| Waited (count) when workers occupied | The number of times that the coordinator thread slept for a short period, which it might do in two situations. The first situation is where the coordinator thread assigns an event and finds the applier worker thread's queue is filled beyond the underrun level of 10% of the maximum queue length, in which case it sleeps for a maximum of 1 millisecond. The second situation is where <code>slave_parallel_type</code> is set to <code>LOGICAL_CLOCK</code> and the coordinator thread needs to assign the first event of a transaction to an applier worker thread's queue, it only does this to a worker with an empty queue, so if no queues are empty, the coordinator thread sleeps until one becomes empty. |
| Waited when workers occupied         | The number of nanoseconds that the coordinator thread slept while waiting for an empty applier worker thread queue (that is, in the second situation described above, where <code>slave_parallel_type</code> is set to <code>LOGICAL_CLOCK</code> and the first event of a transaction needs to be assigned).                                                                                                                                                                                                                                                                                                                                                                                                             |

## 16.2.4 Relay Log and Replication Metadata Repositories

A replica server creates several repositories of information to use for the replication process:

- The *relay log*, which is written by the replication I/O thread, contains the transactions read from the replication source server's binary log. The transactions in the relay log are applied on the replica by the replication SQL thread. For information about the relay log, see [Section 16.2.4.1, “The Relay Log”](#).
- The replica's *connection metadata repository* contains information that the replication I/O thread needs to connect to the replication source server and retrieve transactions from the source's binary log. The connection metadata repository is written to the `mysql.slave_master_info` table or to a file.
- The replica's *applier metadata repository* contains information that the replication SQL thread needs to read and apply transactions from the replica's relay log. The applier metadata repository is written to the `mysql.slave_relay_log_info` table or to a file.

The connection metadata repository and applier metadata repository are collectively known as the replication metadata repositories. For information about these, see [Section 16.2.4.2, “Replication Metadata Repositories”](#).

**Making replication resilient to unexpected halts.** The `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables are created using the transactional storage engine `InnoDB`. Updates to the replica's applier metadata repository table are committed together with the transactions, meaning that the replica's progress information recorded in that repository is always consistent with what has been applied to the database, even in the event of an unexpected server halt. For information on the combination of settings on the replica that is most resilient to unexpected halts, see [Section 16.3.2, “Handling an Unexpected Halt of a Replica”](#).

### 16.2.4.1 The Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#)).

By default, relay log file names have the form `host_name-relay-bin.nnnnnn` in the data directory, where `host_name` is the name of the replica server host and `nnnnnn` is a sequence number.

Successive relay log files are created using successive sequence numbers, beginning with `000001`.

The replica uses an index file to track the relay log files currently in use. The default relay log index file name is `host_name-relay-bin.index` in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the `relay_log` and `relay_log_index` system variables (see [Section 16.1.6, “Replication and Binary Logging Options and Variables”](#)).

If a replica uses the default host-based relay log file names, changing a replica's host name after replication has been set up can cause replication to fail with the errors `Failed to open the relay log` and `Could not find target log during relay log initialization`. This is a known issue (see Bug #2122). If you anticipate that a replica's host name might change in the future (for example, if networking is set up on the replica such that its host name can be modified using DHCP), you can avoid this issue entirely by using the `relay_log` and `relay_log_index` system variables to specify relay log file names explicitly when you initially set up the replica. This makes the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the replica server, prepend the contents of the old relay log index file to the new one, and then restart the replica. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A replica server creates a new relay log file under the following conditions:

- Each time the replication I/O thread starts.
- When the logs are flushed (for example, with `FLUSH LOGS` or `mysqladmin flush-logs`).
- When the size of the current relay log file becomes too large, determined as follows:
  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The replication SQL thread automatically deletes each relay log file after it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the replication SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the replication SQL thread deletes them.

### 16.2.4.2 Replication Metadata Repositories

A replica server creates two replication metadata repositories, the connection metadata repository and the applier metadata repository. The replication metadata repositories survive a replica server's shutdown. If binary log file position based replication is in use, when the replica restarts, it reads the two repositories to determine how far it previously proceeded in reading the binary log from the source and in processing its own relay log. If GTID-based replication is in use, the replica does not use the

replication metadata repositories for that purpose, but does need them for the other metadata that they contain.

- The replica's *connection metadata repository* contains information that the replication I/O thread needs to connect to the replication source server and retrieve transactions from the source's binary log. The metadata in this repository includes the connection configuration, the replication user account details, the SSL settings for the connection, and the file name and position where the replication I/O thread is currently reading from the source's binary log.
- The replica's *applier metadata repository* contains information that the replication SQL thread needs to read and apply transactions from the replica's relay log. The metadata in this repository includes the file name and position up to which the replication SQL thread has executed the transactions in the relay log, and the equivalent position in the source's binary log. It also includes metadata for the process of applying transactions, such as the number of worker threads.

By default, the replication metadata repositories are created as files in the data directory named `master.info` and `relay-log.info`, or with alternative names and locations specified by the `--master-info-file` option and `relay_log_info_file` system variable. To create the replication metadata repositories as tables, specify `master_info_repository=TABLE` and `relay_log_info_repository=TABLE` at server startup. In that case, the replica's connection metadata repository is written to the `slave_master_info` table in the `mysql` system schema, and the replica's applier metadata repository is written to the `slave_relay_log_info` table in the `mysql` system schema. A warning message is issued if `mysqld` is unable to initialize the tables for the replication metadata repositories, but the replica is allowed to continue starting. This situation is most likely to occur when upgrading from a version of MySQL that does not support the use of tables for the repositories to one in which they are supported.

#### Important

1. Do not attempt to update or insert rows in the `mysql.slave_master_info` or `mysql.slave_relay_log_info` tables manually. Doing so can cause undefined behavior, and is not supported. Execution of any statement requiring a write lock on either or both of the `slave_master_info` and `slave_relay_log_info` tables is disallowed while replication is ongoing (although statements that perform only reads are permitted at any time).
2. Access to the replica's connection metadata repository file or table should be restricted to the database administrator, because it contains the replication user account name and password for connecting to the source. Use a restricted access mode to protect database backups that include this repository.

`RESET SLAVE` clears the data in the replication metadata repositories, with the exception of the replication connection parameters (depending on the MySQL Server release and repository type). For details, see the description for `RESET SLAVE`.

If you set `master_info_repository` and `relay_log_info_repository` to `TABLE`, the `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables are created using the `InnoDB` transactional storage engine. Updates to the replica's applier metadata repository table are committed together with the transactions, meaning that the replica's progress information recorded in that repository is always consistent with what has been applied to the database, even in the event of an unexpected server halt. The `--relay-log-recovery` option must be enabled on the replica to guarantee resilience. For more details, see Section 16.3.2, “Handling an Unexpected Halt of a Replica”.

When you back up the replica's data or transfer a snapshot of its data to create a new replica, ensure that you include the `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables containing the replication metadata repositories, or the equivalent files (`master.info` and `relay-log.info` in the data directory, unless you specified alternative names and locations). When binary log file position based replication is in use, the replication metadata repositories are needed to resume

replication after restarting the restored or copied replica. If you do not have the relay log files, but still have the replica's applier metadata repository, you can check it to determine how far the replication SQL thread has executed in the source's binary log. Then you can use a `CHANGE MASTER TO` statement with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the replica to re-read the binary logs from the source from that point (provided that the required binary logs still exist on the source).

One additional repository, the applier worker metadata repository, is created primarily for internal use, and holds status information about worker threads on a multithreaded replica. The applier worker metadata repository includes the names and positions for the relay log file and the source's binary log file for each worker thread. If the replica's applier metadata repository is created as a table, which is the default, the applier worker metadata repository is written to the `mysql.slave_worker_info` table. If the applier metadata repository is written to a file, the applier worker metadata repository is written to the `worker-relay-log.info` file. For external use, status information for worker threads is presented in the Performance Schema `replication_applier_status_by_worker` table.

The replication metadata repositories originally contained information similar to that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in [Section 13.4.2, “SQL Statements for Controlling Replica Servers”](#). Further information has since been added to the replication metadata repositories which is not displayed by the `SHOW SLAVE STATUS` statement.

For the connection metadata repository, the following table shows the correspondence between the columns in the `mysql.slave_master_info` table, the columns displayed by `SHOW SLAVE STATUS`, and the lines in the `master.info` file.

| <code>master.info</code><br>File Line | <code>slave_master_info</code> Table<br>Column | <code>SHOW SLAVE STATUS</code> Column                   | Description                                                                   |
|---------------------------------------|------------------------------------------------|---------------------------------------------------------|-------------------------------------------------------------------------------|
| 1                                     | <code>Number_of_lines</code>                   | [None]                                                  | Number of lines in the file, or columns in the table                          |
| 2                                     | <code>Master_log_name</code>                   | <code>Master_Log_File</code>                            | The name of the binary log currently being read from the source               |
| 3                                     | <code>Master_log_pos</code>                    | <code>Read_Master_Log_Pos</code>                        | The current position within the binary log that has been read from the source |
| 4                                     | <code>Host</code>                              | <code>Master_Host</code>                                | The host name of the source server                                            |
| 5                                     | <code>User_name</code>                         | <code>Master_User</code>                                | The replication user name used to connect to the source                       |
| 6                                     | <code>User_password</code>                     | Password (not shown by <code>SHOW SLAVE STATUS</code> ) | The password used to connect to the source                                    |
| 7                                     | <code>Port</code>                              | <code>Master_Port</code>                                | The network port used to connect to the source                                |
| 8                                     | <code>Connect_retry</code>                     | <code>Connect_Retry</code>                              | The period (in seconds) that the replica waits                                |

| <b>master.info<br/>File Line</b> | <b>slave_master_info Table<br/>Column</b> | <b>SHOW SLAVE STATUS Column</b> | <b>Description</b>                                                                                                                                                    |
|----------------------------------|-------------------------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  |                                           |                                 | before trying to reconnect to the source                                                                                                                              |
| 9                                | Enabled_ssl                               | Master_SSL_Allowed              | Indicates whether the server supports SSL connections                                                                                                                 |
| 10                               | Ssl_ca                                    | Master_SSL_CA_File              | The file used for the Certificate Authority (CA) certificate                                                                                                          |
| 11                               | Ssl_capath                                | Master_SSL_CA_Path              | The path to the Certificate Authority (CA) certificates                                                                                                               |
| 12                               | Ssl_cert                                  | Master_SSL_Cert                 | The name of the SSL certificate file                                                                                                                                  |

|                  |                                       |                                 | attempts permitted                                                   |
| 21               | Ssl_crl                               | [None]                          | Path to an SSL certificate revocation-list file                      |
| 22               | Ssl_crlpath                           | [None]                          | Path to a directory containing SSL certificate revocation-list files |
| 23               | Enabled_auto_position                 | Auto_position                   | If autopositioning is in use or not                                  |
| 24               | Channel_name                          | Channel_name                    | The name of the replication channel                                  |
| 25               | Tls_version                           | Master_TLS_Version              | TLS version on source                                                |

For the applier metadata repository, the following table shows the correspondence between the columns in the `mysql.slave_relay_log_info` table, the columns displayed by `SHOW SLAVE STATUS`, and the lines in the `relay-log.info` file.

| <b>Line in relay-log.info</b> | <b>slave_relay_log_info Table Column</b> | <b>SHOW SLAVE STATUS Column</b> | <b>Description</b>                                                                                                    |
|-------------------------------|------------------------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| 1                             | Number_of_lines                          | [None]                          | Number of lines in the file or columns in the table                                                                   |
| 2                             | Relay_log_name                           | Relay_Log_File                  | The name of the current relay log file                                                                                |
| 3                             | Relay_log_pos                            | Relay_Log_Pos                   | The current position within the relay log file; events up to this position have been executed on the replica database |
| 4                             | Master_log_name                          | Relay_Master_Log_File           | The name of the source's binary log file from which the events in the relay log file were read                        |
| 5                             | Master_log_pos                           | Exec_Master_Log_Pos             | The equivalent position within the source's binary log file of events that have already been executed                 |
| 6                             | Sql_delay                                | SQL_Delay                       | The number of seconds that the replica must lag the source                                                            |

| Line in<br><code>relay-<br/>log.info</code> | <code>slave_relay_log_info</code><br>Table Column | <code>SHOW SLAVE STATUS</code> Column | Description                                                                                             |
|---------------------------------------------|---------------------------------------------------|---------------------------------------|---------------------------------------------------------------------------------------------------------|
| 7                                           | <code>Number_of_workers</code>                    | [None]                                | The number of worker threads on the replica for executing replication events (transactions) in parallel |
| 8                                           | <code>Id</code>                                   | [None]                                | ID used for internal purposes; currently this is always 1                                               |
| 9                                           | <code>Channel_name</code>                         | <code>Channel_name</code>             | The name of the replication channel                                                                     |

In versions of MySQL prior to MySQL 5.6, the `relay-log.info` file does not include a line count or a delay value (and the `slave_relay_log_info` table is not available).

| Line | Status Column                      | Description                                                                                                           |
|------|------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| 1    | <code>Relay_Log_File</code>        | The name of the current relay log file                                                                                |
| 2    | <code>Relay_Log_Pos</code>         | The current position within the relay log file; events up to this position have been executed on the replica database |
| 3    | <code>Relay_Master_Log_File</code> | The name of the source's binary log file from which the events in the relay log file were read                        |
| 4    | <code>Exec_Master_Log_Pos</code>   | The equivalent position within the source's binary log file of events that have already been executed                 |

#### Note

If you downgrade a replica server to a version older than MySQL 5.6, the older server does not read the `relay-log.info` file correctly. To address this, modify the file in a text editor by deleting the initial line containing the number of lines.

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATUS` statement might not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a replica that is offline (that is, `mysqld` is not running). For a running system, you can use `SHOW SLAVE STATUS`, or query the `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables if you are writing the replication metadata repositories to tables.

## 16.2.5 How Servers Evaluate Replication Filtering Rules

If a replication source server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all replicas and each replica determines whether to execute it or ignore it.

On the source, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see [Section 16.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#). You should not use these options to control which databases and tables are replicated. Instead, use filtering on the replica to control the events that are executed on the replica.

On the replica side, decisions about whether to execute or ignore statements received from the source are made according to the `--replicate-*` options that the replica was started with. (See [Section 16.1.6, “Replication and Binary Logging Options and Variables”](#).) The filters governed by these options can also be set dynamically using the `CHANGE REPLICATION FILTER` statement. The rules governing such filters are the same whether they are created on startup using `--replicate-*` options or while the replica server is running by `CHANGE REPLICATION FILTER`. Note that replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state.

In the simplest case, when there are no `--replicate-*` options, the replica executes all statements that it receives from the source. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see [Section 16.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#), for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see [Section 16.2.5.2, “Evaluation of Table-Level Replication Options”](#), for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

For statements affecting databases only (that is, `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), database-level options always take precedence over any `--replicate-wild-do-table` options. In other words, for such statements, `--replicate-wild-do-table` options are checked if and only if there are no database-level options that apply. This is a change in behavior from previous versions of MySQL, where the statement `CREATE DATABASE dbx` was not replicated if the replica had been started with `--replicate-do-db=dbx --replicate-wild-do-table=db% .t1`. (Bug #46110)

To make it easier to determine what effect an option set has, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

#### Note

All replication filtering options follow the same rules for case sensitivity that apply to names of databases and tables elsewhere in the MySQL server, including the effects of the `lower_case_table_names` system variable.

### 16.2.5.1 Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the replica begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the source.

The database that is checked for a match depends on the binary log format of the statement that is being handled. If the statement has been logged using the row format, the database where data is to be changed is the database that is checked. If the statement has been logged using the statement format, the default database (specified with a `USE` statement) is the database that is checked.

#### Note

Only DML statements can be logged using the row format. DDL statements are always logged as statements, even when `binlog_format=ROW`. All DDL statements are therefore always filtered according to the rules for statement-based replication. This means that you must select the default database explicitly with a `USE` statement in order for a DDL statement to be applied.

For replication, the steps involved are listed here:

1. Which logging format is used?
  - **STATEMENT.** Test the default database.
  - **ROW.** Test the database affected by the changes.
2. Are there any `--replicate-do-db` options?
  - **Yes.** Does the database match any of them?
    - **Yes.** Continue to Step 4.
    - **No.** Ignore the update and exit.
  - **No.** Continue to step 3.
3. Are there any `--replicate-ignore-db` options?
  - **Yes.** Does the database match any of them?
    - **Yes.** Ignore the update and exit.
    - **No.** Continue to step 4.
  - **No.** Continue to step 4.
4. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see [Section 16.2.5.2, “Evaluation of Table-Level Replication Options”](#).

#### Important

A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
  - **Yes.** Continue to step 2.
  - **No.** Log the statement and exit.
2. Is there a default database (has any database been selected by `USE`)?
  - **Yes.** Continue to step 3.
  - **No.** Ignore the statement and exit.
3. There is a default database. Are there any `--binlog-do-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Log the statement and exit.
    - **No.** Ignore the statement and exit.
  - **No.** Continue to step 4.
4. Do any of the `--binlog-ignore-db` options match the database?
  - **Yes.** Ignore the statement and exit.

- **No.** Log the statement and exit.

**Important**

For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created*, *altered*, or *dropped* replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

### 16.2.5.2 Evaluation of Table-Level Replication Options

The replica checks for and evaluates table options only if either of the following two conditions is true:

- No matching database options were found.
- One or more database options were found, and were evaluated to arrive at an “execute” condition according to the rules described in the previous section (see [Section 16.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#)).

First, as a preliminary condition, the replica checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the replica executes the statement and exits. If row-based replication is enabled, the replica does not know whether a statement occurred within a stored function on the source, so this condition does not apply.

**Note**

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the replica simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options.

The following steps describe this evaluation in more detail. The starting point is the end of the evaluation of the database-level options, as described in [Section 16.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#).

1. Are there any table replication options?
  - **Yes.** Continue to step 2.
  - **No.** Execute the update and exit.
2. Which logging format is used?
  - **STATEMENT.** Carry out the remaining steps for each statement that performs an update.
  - **ROW.** Carry out the remaining steps for each update of a table row.

3. Are there any `--replicate-do-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Execute the update and exit.
    - **No.** Continue to step 4.
  - **No.** Continue to step 4.
4. Are there any `--replicate-ignore-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Ignore the update and exit.
    - **No.** Continue to step 5.
  - **No.** Continue to step 5.
5. Are there any `--replicate-wild-do-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Execute the update and exit.
    - **No.** Continue to step 6.
  - **No.** Continue to step 6.
6. Are there any `--replicate-wild-ignore-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Ignore the update and exit.
    - **No.** Continue to step 7.
  - **No.** Continue to step 7.
7. Is there another table to be tested?
  - **Yes.** Go back to step 3.
  - **No.** Continue to step 8.
8. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
  - **Yes.** Ignore the update and exit.
  - **No.** Execute the update and exit.

**Note**

Statement-based replication stops if a single SQL statement operates on both a table that is included by a `--replicate-do-table` or `--replicate-wild-do-table` option, and another table that is ignored by a `--replicate-ignore-table` or `--replicate-wild-ignore-table` option. The replica must either execute or ignore the complete statement (which forms a replication event), and it cannot logically do this. This also applies to row-based replication for DDL statements, because DDL statements are always logged as statements, without regard to the logging format in effect. The only type of statement that can update both an included and an ignored table and

still be replicated successfully is a DML statement that has been logged with `binlog_format=ROW`.

### 16.2.5.3 Interactions Between Replication Filtering Options

If you use a combination of database-level and table-level replication filtering options, the replica first accepts or ignores events using the database options, then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive. It is also important to note that the results vary depending on whether the operation is logged using statement-based or row-based binary logging format. If you want to be sure that your replication filters always operate in the same way independently of the binary logging format, which is particularly important if you are using mixed binary logging format, follow the guidance in this topic.

The effect of the replication filtering options differs between binary logging formats because of the way the database name is identified. With statement-based format, DML statements are handled based on the current database, as specified by the `USE` statement. With row-based format, DML statements are handled based on the database where the modified table exists. DDL statements are always filtered based on the current database, as specified by the `USE` statement, regardless of the binary logging format.

An operation that involves multiple tables can also be affected differently by replication filtering options depending on the binary logging format. Operations to watch out for include transactions involving multi-table `UPDATE` statements, triggers, cascading foreign keys, stored functions that update multiple tables, and DML statements that invoke stored functions that update one or more tables. If these operations update both filtered-in and filtered-out tables, the results can vary with the binary logging format.

If you need to guarantee that your replication filters operate consistently regardless of the binary logging format, particularly if you are using mixed binary logging format (`binlog_format=MIXED`), use only table-level replication filtering options, and do not use database-level replication filtering options. Also, do not use multi-table DML statements that update both filtered-in and filtered-out tables.

If you need to use a combination of database-level and table-level replication filters, and want these to operate as consistently as possible, choose one of the following strategies:

1. If you use row-based binary logging format (`binlog_format=ROW`), for DDL statements, rely on the `USE` statement to set the database and do not specify the database name. You can consider changing to row-based binary logging format for improved consistency with replication filtering. See [Section 5.4.4.2, “Setting The Binary Log Format”](#) for the conditions that apply to changing the binary logging format.
2. If you use statement-based or mixed binary logging format (`binlog_format=STATEMENT` or `MIXED`), for both DML and DDL statements, rely on the `USE` statement and do not use the database name. Also, do not use multi-table DML statements that update both filtered-in and filtered-out tables.

#### Example 16.7 A `--replicate-ignore-db` option and a `--replicate-do-table` option

On the source, the following statements are issued:

```
USE db1;
CREATE TABLE t2 LIKE t1;
INSERT INTO db2.t3 VALUES (1);
```

The replica has the following replication filtering options set:

```
replicate-ignore-db = db1
replicate-do-table = db2.t3
```

The DDL statement `CREATE TABLE` creates the table in `db1`, as specified by the preceding `USE` statement. The replica filters out this statement according to its `--replicate-ignore-db = db1` option, because `db1` is the current database. This result is the same whatever the binary logging

format is on the source. However, the result of the DML `INSERT` statement is different depending on the binary logging format:

- If row-based binary logging format is in use on the source (`binlog_format=ROW`), the replica evaluates the `INSERT` operation using the database where the table exists, which is named as `db2`. The database-level option `--replicate-ignore-db = db1`, which is evaluated first, therefore does not apply. The table-level option `--replicate-do-table = db2.t3` does apply, so the replica applies the change to table `t3`.
- If statement-based binary logging format is in use on the source (`binlog_format=STATEMENT`), the replica evaluates the `INSERT` operation using the default database, which was set by the `USE` statement to `db1` and has not been changed. According to its database-level `--replicate-ignore-db = db1` option, it therefore ignores the operation and does not apply the change to table `t3`. The table-level option `--replicate-do-table = db2.t3` is not checked, because the statement already matched a database-level option and was ignored.

If the `--replicate-ignore-db = db1` option on the replica is necessary, and the use of statement-based (or mixed) binary logging format on the source is also necessary, the results can be made consistent by omitting the database name from the `INSERT` statement and relying on a `USE` statement instead, as follows:

```
USE db1;
CREATE TABLE t2 LIKE t1;
USE db2;
INSERT INTO t3 VALUES (1);
```

In this case, the replica always evaluates the `INSERT` statement based on the database `db2`. Whether the operation is logged in statement-based or row-based binary format, the results remain the same.

## 16.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see [Section 16.3.1, “Using Replication for Backups”](#).

For advice and tips on using different storage engines on the source and replicas, see [Section 16.3.3, “Using Replication with Different Source and Replica Storage Engines”](#).

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See [Section 16.3.4, “Using Replication for Scale-Out”](#).

For performance or data distribution reasons, you may want to replicate different databases to different replicas. See [Section 16.3.5, “Replicating Different Databases to Different Replicas”](#)

As the number of replicas increases, the load on the source can increase and lead to reduced performance (because of the need to replicate the binary log to each replica). For tips on improving your replication performance, including using a single secondary server as a replication source server, see [Section 16.3.6, “Improving Replication Performance”](#).

For guidance on switching sources, or converting replicas into sources as part of an emergency failover solution, see [Section 16.3.7, “Switching Sources During Failover”](#).

To secure your replication communication, you can encrypt the communication channel. For step-by-step instructions, see [Section 16.3.8, “Setting Up Replication to Use Encrypted Connections”](#).

### 16.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the source to a replica, and then back up the replica. The replica can be paused and shut down without affecting the running operation of the

source, so you can produce an effective snapshot of “live” data that would otherwise require the source to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replica state so that you can rebuild the replica in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the source, and the size of your database is not too large, the `mysqldump` tool may be suitable. See [Section 16.3.1.1, “Backing Up a Replica Using mysqldump”](#).
- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that enable you to re-create the replica in the event of a replica failure. For more information, see [Section 16.3.1.2, “Backing Up Raw Data from a Replica”](#).

Another backup strategy, which can be used for either source or replica servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See [Section 16.3.1.3, “Backing Up a Source or Replica by Making It Read Only”](#).

### 16.3.1.1 Backing Up a Replica Using mysqldump

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see [Section 4.5.4, “mysqldump — A Database Backup Program”](#)). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the replica before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the replica from processing requests. You can stop replication completely on the replica using `mysqladmin`:

```
shell> mysqladmin stop-slave
```

Alternatively, you can stop only the replication SQL thread to pause event execution:

```
shell> mysql -e 'STOP SLAVE SQL_THREAD;'
```

This enables the replica to continue to receive data change events from the source's binary log and store them in the relay logs using the I/O thread, but prevents the replica from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the replication SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

```
shell> mysqldump --all-databases > fulldb.dump
```

3. Once the dump has completed, start replica operations again:

```
shell> mysqladmin start-slave
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the replication process to ensure that the time taken to run the backup does not affect the replica's ability to keep up with events from the source. See

[Section 16.1.7.1, “Checking Replication Status”](#). If the replica is unable to keep up, you may want to add another replica and distribute the backup process. For an example of how to configure this scenario, see [Section 16.3.5, “Replicating Different Databases to Different Replicas”](#).

### 16.3.1.2 Backing Up Raw Data from a Replica

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replica should take place while your replica server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as [InnoDB](#). With [InnoDB](#), these problems should be resolved during crash recovery, but since the replica server can be shut down during the backup process without affecting the execution of the source it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the replica MySQL server:

```
shell> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including [cp](#), [tar](#) or [WinZip](#). For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

```
shell> tar cf /tmp/dbbackup.tar ./data
```

3. Start the MySQL server again. Under Unix:

```
shell> mysqld_safe &
```

Under Windows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld"
```

Normally you should back up the entire data directory for the replica MySQL server. If you want to be able to restore the data and operate as a replica (for example, in the event of failure of the replica), then in addition to the replica's data, you should also back up the replica status files, the replication metadata repositories, and the relay log files. These files are needed to resume replication after you restore the replica's data.

If you lose the relay logs but still have the [relay-log.info](#) file, you can check it to determine how far the replication SQL thread has executed in the source's binary logs. Then you can use [CHANGE MASTER TO](#) with the [MASTER\\_LOG\\_FILE](#) and [MASTER\\_LOG\\_POS](#) options to tell the replica to re-read the binary logs from that point. This requires that the binary logs still exist on the source server.

If your replica is replicating [LOAD DATA](#) statements, you should also back up any [SQL\\_LOAD-\\*](#) files that exist in the directory that the replica uses for this purpose. The replica needs these files to resume replication of any interrupted [LOAD DATA](#) operations. The location of this directory is the value of the [slave\\_load\\_tmpdir](#) system variable. If the server was not started with that variable set, the directory location is the value of the [tmpdir](#) system variable.

### 16.3.1.3 Backing Up a Source or Replica by Making It Read Only

It is possible to back up either source or replica servers in a replication setup by acquiring a global read lock and manipulating the [read\\_only](#) system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.
2. Perform the backup.
3. Change the server back to its normal read/write state.

**Note**

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see [Section 4.5.4, “mysqldump — A Database Backup Program”](#)). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a source server and for a replica server. For both scenarios discussed here, suppose that you have the following replication setup:

- A source server S1
- A replica server R1 that has S1 as its source
- A client C1 connected to S1
- A client C2 connected to R1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any replicas of that server.

**Scenario 1: Backup with a Read-Only Source**

Put the source S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to S1 block because the server is in read-only mode.
- Requests for query results sent by C1 to S1 succeed.
- Making a backup on S1 is safe.
- Making a backup on R1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

Although performing the backup on S1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of S1 are blocked from executing updates.

This strategy applies to backing up a source server in a replication setup, but can also be used for a single server in a nonreplication setting.

**Scenario 2: Backup with a Read-Only Replica**

Put the replica R1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

```
mysql> SET GLOBAL read_only = ON;
```

While R1 is in a read-only state, the following properties are true:

- The source S1 continues to operate, so making a backup on the source is not safe.
- The replica R1 is stopped, so making a backup on the replica R1 is safe.

These properties provide the basis for a popular backup scenario: Having one replica busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the source server, which remains unaffected by backup activity on the replica.

While R1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on R1 completes, restore R1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the replica is restored to normal operation, it again synchronizes to the source by catching up with any outstanding updates from the binary log of the source.

### 16.3.2 Handling an Unexpected Halt of a Replica

In order for replication to be resilient to unexpected halts of the server (sometimes described as crash-safe) it must be possible for the replica to recover its state before halting. This section describes the impact of an unexpected halt of a replica during replication, and how to configure a replica for the best chance of recovery to continue replication.

After an unexpected halt of a replica, upon restart the replication SQL thread must recover information about which transactions have been executed already. The information required for recovery is stored in the replica's applier metadata repository. In older MySQL Server versions, this repository could only be created as a file in the data directory that was updated after the transaction had been applied. In MySQL 5.7 you can instead use an `InnoDB` table named `mysql.slave_relay_log_info` to store the applier metadata repository. As a table, updates to the applier metadata repository are committed together with the transactions, meaning that the replica's progress information recorded in that repository is always consistent with what has been applied to the database, even in the event of an unexpected server halt. To configure MySQL 5.7 to store the applier metadata repository as an `InnoDB` table, set the system variable `relay_log_info_repository` to `TABLE`. For more information on the applier metadata repository, see [Section 16.2.4, “Relay Log and Replication Metadata Repositories”](#).

The recovery process by which a replica recovers from an unexpected halt varies depending on the configuration of the replica. The details of the recovery process are influenced by the chosen method of replication, whether the replica is single-threaded or multithreaded, and the setting of relevant system variables. The overall aim of the recovery process is to identify what transactions had already been applied on the replica's database before the unexpected halt occurred, and retrieve and apply the transactions that the replica missed following the unexpected halt.

- For GTID-based replication, the recovery process needs the GTIDs of the transactions that were already received or committed by the replica. The missing transactions can be retrieved from the source using GTID auto-positioning, which automatically compares the source's transactions to the replica's transactions and identifies the missing transactions.
- For file position based replication, the recovery process needs an accurate replication SQL thread (applier) position showing the last transaction that was applied on the replica. Based on that position, the replication I/O thread (receiver) retrieves from the source's binary log all of the transactions that should be applied on the replica from that point on.

Using GTID-based replication makes it easiest to configure replication to be resilient to unexpected halts. GTID auto-positioning means the replica can reliably identify and retrieve missing transactions, even if there are gaps in the sequence of applied transactions.

The following information provides combinations of settings that are appropriate for different types of replica to guarantee recovery as far as this is under the control of replication.

### Important

Some factors outside the control of replication can have an impact on the replication recovery process and the overall state of replication after the recovery process. In particular, the settings that influence the recovery process for individual storage engines might result in transactions being lost in the event of an unexpected halt of a replica, and therefore unavailable to the replication recovery process. The `innodb_flush_log_at_trx_commit=1` setting mentioned in the list below is a key setting for a replication setup that uses InnoDB with transactions. However, other settings specific to InnoDB or to other storage engines, especially those relating to flushing or synchronization, can also have an impact. Always check for and apply recommendations made by your chosen storage engines about crash-safe settings.

The following combination of settings on a replica is the most resilient to unexpected halts:

- When GTID-based replication is in use (`gtid_mode=ON`), set `MASTER_AUTO_POSITION=1`, which activates GTID auto-positioning for the connection to the source to automatically identify and retrieve missing transactions. This option is set using a `CHANGE MASTER TO` statement. If the replica has multiple replication channels, you need to set this option for each channel individually. For details of how GTID auto-positioning works, see [Section 16.1.3.3, “GTID Auto-Positioning”](#). When file position based replication is in use, `MASTER_AUTO_POSITION=1` is not used, and instead the binary log position or relay log position is used to control where replication starts.
- Set `sync_relay_log=1`, which instructs the replication I/O thread to synchronize the relay log to disk after each received transaction is written to it. This means the replica's record of the current position read from the source's binary log (in the source metadata repository) is never ahead of the record of transactions saved in the relay log. Note that although this setting is the safest, it is also the slowest due to the number of disk writes involved. With `sync_relay_log > 1`, or `sync_relay_log=0` (where synchronization is handled by the operating system), in the event of an unexpected halt of a replica there might be committed transactions that have not been synchronized to disk. Such transactions can cause the recovery process to fail if the recovering replica, based on the information it has in the relay log as last synchronized to disk, tries to retrieve and apply the transactions again instead of skipping them. Setting `sync_relay_log=1` is particularly important for a multi-threaded replica, where the recovery process fails if gaps in the sequence of transactions cannot be filled using the information in the relay log. For a single-threaded replica, the recovery process only needs to use the relay log if the relevant information is not available in the applier metadata repository.
- Set `innodb_flush_log_at_trx_commit=1`, which synchronizes the InnoDB logs to disk before each transaction is committed. This setting, which is the default, ensures that InnoDB tables and the InnoDB logs are saved on disk so that there is no longer a requirement for the information in the relay log regarding the transaction. Combined with the setting `sync_relay_log=1`, this setting further ensures that the content of the InnoDB tables and the InnoDB logs is consistent with the content of the relay log at all times, so that purging the relay log files cannot cause unfillable gaps in the replica's history of transactions in the event of an unexpected halt.
- Set `relay_log_info_repository = TABLE`, which stores the replication SQL thread position in the InnoDB table `mysql.slave_relay_log_info`, and updates it together with the transaction commit to ensure a record that is always accurate. This setting is *not* the default in MySQL 5.7. If the default `FILE` setting is used, the information is stored in a file in the data directory that is updated after the transaction has been applied. This creates a risk of losing synchrony with the source

depending at which stage of processing a transaction the replica halts at, or even corruption of the file itself. With the setting `relay_log_info_repository = FILE`, recovery is not guaranteed.

- Set `relay_log_recovery = ON`, which enables automatic relay log recovery immediately following server startup. This global variable defaults to `OFF` and is read-only at runtime, but you can set it to `ON` with the `--relay-log-recovery` option at replica startup following an unexpected halt of a replica. Note that this setting ignores the existing relay log files, in case they are corrupted or inconsistent. The relay log recovery process starts a new relay log file and fetches transactions from the source beginning at the replication SQL thread position recorded in the applier metadata repository. The previous relay log files are removed over time by the replica's normal purge mechanism.

For a multithreaded replica, from MySQL 5.7.13, setting `relay_log_recovery = ON` automatically handles any inconsistencies and gaps in the sequence of transactions that have been executed from the relay log. These gaps can occur when file position based replication is in use. (For more details, see [Section 16.4.1.32, “Replication and Transaction Inconsistencies”](#).) The relay log recovery process deals with gaps using the same method as the `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` statement would. When the replica reaches a consistent gap-free state, the relay log recovery process goes on to fetch further transactions from the source beginning at the replication SQL thread position. In MySQL versions prior to MySQL 5.7.13, this process was not automatic and required starting the server with `relay_log_recovery = OFF`, starting the replica with `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to fix any transaction inconsistencies, and then restarting the replica with `relay_log_recovery = ON`. When GTID-based replication is in use, from MySQL 5.7.28 a multithreaded replica checks first whether `MASTER_AUTO_POSITION` is set to `ON`, and if it is, omits the step of calculating the transactions that should be skipped or not skipped, so that the old relay logs are not required for the recovery process.

### 16.3.3 Using Replication with Different Source and Replica Storage Engines

It does not matter for the replication process whether the source table on the source and the replicated table on the replica use different engine types. In fact, the `default_storage_engine` and `storage_engine` system variables are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see [Section 16.3.4, “Using Replication for Scale-Out”](#)), you want to use `InnoDB` tables on the source to take advantage of the transactional functionality, but use `MyISAM` on the replicas where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the `Archive` storage engine on the replica.

Configuring different engines on the source and replica depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your source, you could edit the dump file text to change the engine type used on each table.

Another alternative for `mysqldump` is to disable engine types that you do not want to use on the replica before using the dump to build the data on the replica. For example, you can add the `--skip-federated` option on your replica to disable the `FEDERATED` engine. If a specific engine does not exist for a table to be created, MySQL uses the default engine type, usually `MyISAM`. (This requires that the `NO_ENGINE_SUBSTITUTION` SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the replica that supports only the engines you want.

- If you are using raw data files (a binary backup) to set up the replica, you cannot change the initial table format. Instead, use `ALTER TABLE` to change the table types after the replica has been started.
- For new source/replica replication setups where there are currently no tables on the source, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the replica from running replication updates:

```
mysql> STOP SLAVE;
```

This enables you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.
3. Start the replication process again:

```
mysql> START SLAVE;
```

Although the `default_storage_engine` variable is not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification are correctly replicated to the replica. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The previous statement is replicated to the replica and the engine type on the replica is converted to `MyISAM`, even if you have previously changed the table type on the replica to an engine other than CSV. If you want to retain engine differences on the source and replica, you should be careful to use the `default_storage_engine` variable on the source when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET default_storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `default_storage_engine` variable will be ignored, and the `CREATE TABLE` statement executes on the replica using the replica's default engine.

#### 16.3.4 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one source to one or more replicas, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most websites fit into this category, where users are browsing the website, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replicas, while still enabling your web servers to communicate with the source when a write is required. You can see a sample replication layout for this scenario in [Figure 16.1, “Using Replication to Improve Performance During Scale-Out”](#).

**Figure 16.1 Using Replication to Improve Performance During Scale-Out**

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the source, and to send reads to either the source or a replica. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`

- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a source/replica configuration, even one involving multiple replicas. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions (for example, to log how long each statement took, or which statement among those issued gave you an error).

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

### 16.3.5 Replicating Different Databases to Different Replicas

There may be situations where you have a single source and want to replicate different databases to different replicas. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in Figure 16.2, “Replicating Databases to Separate Replicas”.

**Figure 16.2 Replicating Databases to Separate Replicas**

You can achieve this separation by configuring the source and replicas as normal, and then limiting the binary log statements that each replica processes by using the `--replicate-wild-do-table` configuration option on each replica.

#### Important

You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's effects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in Figure 16.2, “Replicating Databases to Separate Replicas”, you should configure each replica as follows, before executing `START SLAVE`:

- Replica 1 should use `--replicate-wild-do-table=databaseA.%`.

- Replica 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replica 3 should use `--replicate-wild-do-table=databaseC.%`.

Each replica in this configuration receives the entire binary log from the source, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that replica.

If you have data that must be synchronized to the replicas before replication starts, you have a number of choices:

- Synchronize all the data to each replica, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each replica.
- Use a raw data file dump and include only the specific files and databases that you need for each replica.

#### Note

This does not work with `InnoDB` databases unless you use `innodb_file_per_table`.

### 16.3.6 Improving Replication Performance

As the number of replicas connecting to a source increases, the load, although minimal, also increases, as each replica uses a client connection to the source. Also, as each replica must receive a full copy of the source's binary log, the network load on the source may also increase and create a bottleneck.

If you are using a large number of replicas connected to one source, and that source is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the source to replicate to only one replica, and for the remaining replicas to connect to this primary replica for their individual replication requirements. A sample of this structure is shown in [Figure 16.3, “Using an Additional Replication Source to Improve Performance”](#).

**Figure 16.3 Using an Additional Replication Source to Improve Performance**

For this to work, you must configure the MySQL instances as follows:

- Source 1 is the primary source where all changes and updates are written to the database. Binary logging should be enabled on this machine.
- Source 2 is the replica of Source 1 that provides the replication functionality to the remainder of the replicas in the replication structure. Source 2 is the only machine permitted to connect to Source 1. Source 2 also has binary logging enabled, and the `log_slave_updates` system variable enabled so that replication instructions from Source 1 are also written to Source 2's binary log so that they can then be replicated to the true replicas.
- Replica 1, Replica 2, and Replica 3 act as replicas to Source 2, and replicate the information from Source 2, which actually consists of the upgrades logged on Source 1.

The above solution reduces the client load and the network interface load on the primary source, which should improve the overall performance of the primary source when used as a direct database solution.

If your replicas are having trouble keeping up with the replication process on the source, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, set the `relay_log` system variable to specify the location of the relay log.
- If the replicas are significantly slower than the source, you may want to divide up the responsibility for replicating different databases to different replicas. See [Section 16.3.5, “Replicating Different Databases to Different Replicas”](#).
- If your source makes use of transactions and you are not concerned about transaction support on your replicas, use `MyISAM` or another nontransactional engine on the replicas. See [Section 16.3.3, “Using Replication with Different Source and Replica Storage Engines”](#).
- If your replicas are not acting as sources, and you have a potential solution in place to ensure that you can bring up a source in the event of failure, then you can disable the `log_slave_updates` system variable on the replicas. This prevents “dumb” replicas from also logging events they have executed into their own binary log.

### 16.3.7 Switching Sources During Failover

You can tell a replica to change to a new source using the `CHANGE MASTER TO` statement. The replica does not check whether the databases on the source are compatible with those on the replica; it simply begins reading and executing events from the specified coordinates in the new source's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Replicas should be run with the `--log-bin` option, and if not using GTIDs then they should also be run without enabling the `log_slave_updates` system variable. In this way, the replica is ready to become a source without restarting the replica `mysqld`. Assume that you have the structure shown in [Figure 16.4, “Redundancy Using Replication, Initial Structure”](#).

**Figure 16.4 Redundancy Using Replication, Initial Structure**

In this diagram, the `MySQL Source` holds the source database, the `Replica` hosts are replicas, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the replicas) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see [Section 16.3.4, “Using Replication for Scale-Out”](#).

Each MySQL replica (`Replica 1`, `Replica 2`, and `Replica 3`) is a replica running with `--log-bin` and without enabling the `log_slave_updates` system variable. Because updates received by a replica from the source are not logged in the binary log unless `log_slave_updates` is enabled, the binary log on each replica is empty initially. If for some reason `MySQL Source` becomes unavailable, you can pick one of the replicas to become the new source. For example, if you pick `Replica 1`, all `Web Clients` should be redirected to `Replica 1`, which writes the updates to its binary log. `Replica 2` and `Replica 3` should then replicate from `Replica 1`.

The reason for running the replica without `log_slave_updates` enabled is to prevent replicas from receiving updates twice in case you cause one of the replicas to become the new source. If `Replica 1` has `log_slave_updates` enabled, it writes any updates that it receives from `MySQL Source` in its own binary log. This means that, when `Replica 2` changes from `MySQL Source` to `Replica 1` as its source, it may receive updates from `Replica 1` that it has already received from `MySQL Source`.

Make sure that all replicas have processed any statements in their relay log. On each replica, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all replicas, they can be reconfigured to the new setup. On the replica `Replica 1` being promoted to become the source, issue `STOP SLAVE` and `RESET MASTER`.

On the other replicas `Replica 2` and `Replica 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Replica1'` (where '`Replica1`' represents the real host name of `Replica 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Replica 1` from `Replica 2` or `Replica 3` (`user`, `password`, `port`). When issuing the `CHANGE MASTER TO` statement in

this, there is no need to specify the name of the `Replica 1` binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute `START SLAVE` on `Replica 2` and `Replica 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Replica 1`. From that point on, all update statements sent by `Web Client` to `Replica 1` are written to the binary log of `Replica 1`, which then contains every update statement sent to `Replica 1` since `MySQL Source` failed.

The resulting server structure is shown in [Figure 16.5, “Redundancy Using Replication, After Source Failure”](#).

**Figure 16.5 Redundancy Using Replication, After Source Failure**

When `MySQL Source` becomes available again, you should make it a replica of `Replica 1`. To do this, issue on `MySQL Source` the same `CHANGE MASTER TO` statement as that issued on `Replica 2` and `Replica 3` previously. `MySQL Source` then becomes a replica of `Replica 1` and picks up the `Web Client` writes that it missed while it was offline.

To make `MySQL Source` a source again, use the preceding procedure as if `Replica 1` was unavailable and `MySQL Source` was to be the new source. During this procedure, do not forget to run `RESET MASTER` on `MySQL Source` before making `Replica 1`, `Replica 2`, and `Replica 3` replicas of `MySQL Source`. If you fail to do this, the replicas may pick up stale writes from the `Web Client` applications dating from before the point at which `MySQL Source` became unavailable.

You should be aware that there is no synchronization between replicas, even when they share the same source, and thus some replicas might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all replicas should be relatively close together.

One way to keep applications informed about the location of the source is to have a dynamic DNS entry for the source. With `bind` you can use `nsupdate` to update the DNS dynamically.

## 16.3.8 Setting Up Replication to Use Encrypted Connections

To use an encrypted connection for the transfer of the binary log required during replication, both the source and the replica servers must support encrypted network connections. If either server does not support encrypted connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up encrypted connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the source, and a similar certificate (from the same certificate authority) on each replica. You must also obtain suitable key files.

For more information on setting up a server and client for encrypted connections, see [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

To enable encrypted connections on the source, you must create or obtain suitable certificate and key files, and then add the following configuration parameters to the source's configuration within the `[mysqld]` section of the source's `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl_ca=cacert.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
```

The paths to the files may be relative or absolute; we recommend that you always use complete paths for this purpose.

The configuration parameters are as follows:

- `ssl_ca`: The path name of the Certificate Authority (CA) certificate file. (`--ssl-capath` is similar but specifies the path name of a directory of CA certificate files.)
- `ssl_cert`: The path name of the server public key certificate file. This certificate can be sent to the client and authenticated against the CA certificate that it has.
- `ssl_key`: The path name of the server private key file.

To enable encrypted connections on the replica, use the `CHANGE MASTER TO` statement. You can either name the replica certificate and SSL private key files required for the encrypted connection in the `[client]` section of the replica's `my.cnf` file, or you can explicitly specify that information using the `CHANGE MASTER TO` statement. For more information on the `CHANGE MASTER TO` statement, see [Section 13.4.2.1, “CHANGE MASTER TO Statement”](#).

- To name the replica certificate and key files using an option file, add the following lines to the `[client]` section of the replica's `my.cnf` file, changing the file names as necessary:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

- Restart the replica server, using the `--skip-slave-start` option to prevent the replica from connecting to the source. Use `CHANGE MASTER TO` to specify the source configuration, and add the `MASTER_SSL` option to connect using encryption:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='source_hostname',
-> MASTER_USER='repl',
-> MASTER_PASSWORD='password',
-> MASTER_SSL=1;
```

Setting `MASTER_SSL=1` for a replication connection and then setting no further `MASTER_SSL_xxx` options corresponds to setting `--ssl-mode=REQUIRED` for the client, as described in [Command Options for Encrypted Connections](#). With `MASTER_SSL=1`, the connection attempt only succeeds

if an encrypted connection can be established. A replication connection does not fall back to an unencrypted connection, so there is no setting corresponding to the `--ssl-mode=PREFERRED` setting for replication. If `MASTER_SSL=0` is set, this corresponds to `--ssl-mode=DISABLED`.

- To name the replica certificate and SSL private key files using the `CHANGE MASTER TO` statement, if you did not do this in the replica's `my.cnf` file, add the appropriate `MASTER_SSL_xxx` options:

```
-> MASTER_SSL_CA = 'ca_file_name',
-> MASTER_SSL_CAPATH = 'ca_directory_name',
-> MASTER_SSL_CERT = 'cert_file_name',
-> MASTER_SSL_KEY = 'key_file_name',
```

These options correspond to the `--ssl-xxx` options with the same names, as described in [Command Options for Encrypted Connections](#). For these options to take effect, `MASTER_SSL=1` must also be set. For a replication connection, specifying a value for either of `MASTER_SSL_CA` or `MASTER_SSL_CAPATH`, or specifying these options in the replica's `my.cnf` file, corresponds to setting `--ssl-mode=VERIFY_CA`. The connection attempt only succeeds if a valid matching Certificate Authority (CA) certificate is found using the specified information.

- To activate host name identity verification, add the `MASTER_SSL_VERIFY_SERVER_CERT` option:

```
-> MASTER_SSL_VERIFY_SERVER_CERT=1,
```

This option corresponds to the `--ssl-verify-server-cert` option, which is deprecated as of MySQL 5.7.11 and is removed in MySQL 8.0. For a replication connection, specifying `MASTER_SSL_VERIFY_SERVER_CERT=1` corresponds to setting `--ssl-mode=VERIFY_IDENTITY`, as described in [Command Options for Encrypted Connections](#). For this option to take effect, `MASTER_SSL=1` must also be set. Host name identity verification does not work with self-signed certificates.

- To activate certificate revocation list (CRL) checks, add the `MASTER_SSL_CRL` or `MASTER_SSL_CRLPATH` option:

```
-> MASTER_SSL_CRL = 'crl_file_name',
-> MASTER_SSL_CRLPATH = 'crl_directory_name',
```

These options correspond to the `--ssl-xxx` options with the same names, as described in [Command Options for Encrypted Connections](#). If they are not specified, no CRL checking takes place.

- To specify lists of ciphers and encryption protocols permitted by the replica for the replication connection, add the `MASTER_SSL_CIPHER` and `MASTER_TLS_VERSION` options:

```
-> MASTER_SSL_CIPHER = 'cipher_list',
-> MASTER_TLS_VERSION = 'protocol_list',
```

The `MASTER_SSL_CIPHER` option specifies the list of ciphers permitted by the replica for the replication connection, with one or more cipher names separated by colons. The `MASTER_TLS_VERSION` option specifies the encryption protocols permitted by the replica for the replication connection. The format is like that for the `tls_version` system variable, with one or more comma-separated protocol versions. The protocols and ciphers that you can use in these lists depend on the SSL library used to compile MySQL. For information about the formats and permitted values, see [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- After the source information has been updated, start the replication process:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` statement to confirm that an encrypted connection was established successfully.

- Requiring encrypted connections on the replica does not ensure that the source requires encrypted connections from replicas. If you want to ensure that the source only accepts replicas that connect

using encrypted connections, create a replication user account on the source using the `REQUIRE SSL` option, then grant that user the `REPLICATION SLAVE` privilege. For example:

```
mysql> CREATE USER 'repl'@'%.example.com' IDENTIFIED BY 'password'
 -> REQUIRE SSL;
mysql> GRANT REPLICATION SLAVE ON *.*
 -> TO 'repl'@'%.example.com';
```

If you have an existing replication user account on the source, you can add `REQUIRE SSL` to it with this statement:

```
mysql> ALTER USER 'repl'@'%.example.com' REQUIRE SSL;
```

### 16.3.9 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 5.7 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The source writes events to its binary log and replicas request them when they are ready. The source does not know whether or when a replica has retrieved and processed the transactions, and there is no guarantee that any event ever reaches any replica. With asynchronous replication, if the source crashes, transactions that it has committed might not have been transmitted to any replica. Failover from source to replica in this case might result in failover to a server that is missing transactions relative to the source.

With fully synchronous replication, when a source commits a transaction, all replicas must also have committed the transaction before the source returns to the session that performed the transaction. Fully synchronous replication means failover from the source to any replica is possible at any time. The drawback of fully synchronous replication is that there might be a lot of delay to complete a transaction.

Semisynchronous replication falls between asynchronous and fully synchronous replication. The source waits until at least one replica has received and logged the events (the required number of replicas is configurable), and then commits the transaction. The source does not wait for all replicas to acknowledge receipt, and it requires only an acknowledgement from the replicas, not that the events have been fully executed and committed on the replica side. Semisynchronous replication therefore guarantees that if the source crashes, all the transactions that it has committed have been transmitted to at least one replica.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity, because when a commit returns successfully, it is known that the data exists in at least two places. Until a semisynchronous source receives acknowledgment from the required number of replicas, the transaction is on hold and not committed.

Compared to fully synchronous replication, semisynchronous replication is faster, because it can be configured to balance your requirements for data integrity (the number of replicas acknowledging receipt of the transaction) with the speed of commits, which are slower due to the need to wait for replicas.

#### Important

With semisynchronous replication, if the source crashes and a failover to a replica is carried out, the failed source should not be reused as the replication source server, and should be discarded. It could have transactions that were not acknowledged by any replica, which were therefore not committed before the failover.

If your goal is to implement a fault-tolerant replication topology where all the servers receive the same transactions in the same order, and a server that crashes can rejoin the group and be brought up to date automatically, you can

I use Group Replication to achieve this. For information, see [Chapter 17, Group Replication](#).

The performance impact of semisynchronous replication compared to asynchronous replication is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the replica and wait for the acknowledgment of receipt by the replica. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks. Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from source to replica. When one user is too busy, this slows it down, which can be useful in some deployment situations.

Semisynchronous replication between a source and its replicas operates as follows:

- A replica indicates whether it is semisynchronous-capable when it connects to the source.
- If semisynchronous replication is enabled on the source side and there is at least one semisynchronous replica, a thread that performs a transaction commit on the source blocks and waits until at least one semisynchronous replica acknowledges that it has received all events for the transaction, or until a timeout occurs.
- The replica acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.
- If a timeout occurs without any replica having acknowledged the transaction, the source reverts to asynchronous replication. When at least one semisynchronous replica catches up, the source returns to semisynchronous replication.
- Semisynchronous replication must be enabled on both the source and replica sides. If semisynchronous replication is disabled on the source, or enabled on the source but on no replicas, the source uses asynchronous replication.

While the source is blocking (waiting for acknowledgment from a replica), it does not return to the session that performed the transaction. When the block ends, the source returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the source side, and receipt of its events has been acknowledged by at least one replica. The number of replica acknowledgments the source must receive per transaction before returning to the session is configurable using the `rpl_semi_sync_master_wait_for_slave_count` system variable, for which the default value is 1.

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to replicas.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the source blocks for each such statement, just as it does for explicit transaction commits.

The `rpl_semi_sync_master_wait_point` system variable controls the point at which a semisynchronous replication source waits for replica acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- `AFTER_SYNC` (the default): The source writes each transaction to its binary log and the replica, and syncs the binary log to disk. The source waits for replica acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the source commits the transaction to the storage engine and returns a result to the client, which then can proceed.
- `AFTER_COMMIT`: The source writes each transaction to its binary log and the replica, syncs the binary log, and commits the transaction to the storage engine. The source waits for replica

acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the source returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- With [AFTER\\_SYNC](#), all clients see the committed transaction at the same time, which is after it has been acknowledged by the replica and committed to the storage engine on the source. Thus, all clients see the same data on the source.

In the event of source failure, all transactions committed on the source have been replicated to the replica (saved to its relay log). An unexpected exit of the source and failover to the replica is lossless because the replica is up to date. As noted above, the source should not be reused after the failover.

- With [AFTER\\_COMMIT](#), the client issuing the transaction gets a return status only after the server commits to the storage engine and receives replica acknowledgment. After the commit and before replica acknowledgment, other clients can see the committed transaction before the committing client.

If something goes wrong such that the replica does not process the transaction, then in the event of an unexpected source exit and failover to the replica, it is possible that such clients see a loss of data relative to what they saw on the source.

#### 16.3.9.1 Semisynchronous Replication Administrative Interface

The administrative interface to semisynchronous replication has several components:

- Two plugins implement semisynchronous capability. There is one plugin for the source side and one for the replica side.
- System variables control plugin behavior. Some examples:
  - [rpl\\_semi\\_sync\\_master\\_enabled](#)

Controls whether semisynchronous replication is enabled on the source. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).

- [rpl\\_semi\\_sync\\_master\\_timeout](#)

A value in milliseconds that controls how long the source waits on a commit for acknowledgment from a replica before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

- [rpl\\_semi\\_sync\\_slave\\_enabled](#)

Similar to [rpl\\_semi\\_sync\\_master\\_enabled](#), but controls the replica plugin.

All [rpl\\_semi\\_sync\\_xxx](#) system variables are described at [Section 16.1.6.2, “Replication Source Options and Variables”](#) and [Section 16.1.6.3, “Replica Server Options and Variables”](#).

- From MySQL 5.7.33, you can improve the performance of semisynchronous replication by enabling the system variables [replication\\_sender\\_observe\\_commit\\_only](#), which limits callbacks, and [replication\\_optimize\\_for\\_static\\_plugin\\_config](#), which adds shared locks and avoids unnecessary lock acquisitions. These settings help as the number of replicas increases, because contention for locks can slow down performance. Semisynchronous replication source servers can also get performance benefits from enabling these system variables, because they use the same locking mechanisms as the replicas.
- Status variables enable semisynchronous replication monitoring. Some examples:
  - [Rpl\\_semi\\_sync\\_master\\_clients](#)

The number of semisynchronous replicas.

- `Rpl_semi_sync_master_status`

Whether semisynchronous replication currently is operational on the source. The value is 1 if the plugin has been enabled and a commit acknowledgment has not occurred. It is 0 if the plugin is not enabled or the source has fallen back to asynchronous replication due to commit acknowledgment timeout.

- `Rpl_semi_sync_master_no_tx`

The number of commits that were not acknowledged successfully by a replica.

- `Rpl_semi_sync_master_yes_tx`

The number of commits that were acknowledged successfully by a replica.

- `Rpl_semi_sync_slave_status`

Whether semisynchronous replication currently is operational on the replica. This is 1 if the plugin has been enabled and the replication I/O thread is running, 0 otherwise.

All `Rpl_semi_sync_xxx` status variables are described at [Section 5.1.9, “Server Status Variables”](#).

The system and status variables are available only if the appropriate source or replica plugin has been installed with `INSTALL PLUGIN`.

### 16.3.9.2 Semisynchronous Replication Installation and Configuration

Semisynchronous replication is implemented using plugins, so the plugins must be installed into the server to make them available. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are unavailable until the associated plugin has been installed.

This section describes how to install the semisynchronous replication plugins. For general information about installing plugins, see [Section 5.5.1, “Installing and Uninstalling Plugins”](#).

To use semisynchronous replication, the following requirements must be satisfied:

- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.
- Replication must already be working, see [Section 16.1, “Configuring Replication”](#).
- There must not be multiple replication channels configured. Semisynchronous replication is only compatible with the default replication channel. See [Section 16.2.2, “Replication Channels”](#).

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP SLAVE`, and `START SLAVE` statements mentioned here require the `SUPER` privilege.

MySQL distributions include semisynchronous replication plugin files for the source side and the replica side.

To be usable by a source or replica server, the appropriate plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base names are `semisync_master` and `semisync_slave`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

The source plugin library file must be present in the plugin directory of the source server. The replica plugin library file must be present in the plugin directory of each replica server.

To load the plugins, use the `INSTALL PLUGIN` statement on the source and on each replica that is to be semisynchronous, adjusting the `.so` suffix for your platform as necessary.

On the source:

```
INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
```

On each replica:

```
INSTALL PLUGIN rpl_semi_sync_slave SONAME 'semisync_slave.so';
```

If an attempt to install a plugin results in an error on Linux similar to that shown here, you must install `libimf`:

```
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
ERROR 1126 (HY000): Can't open shared library
'/usr/local/mysql/lib/plugin/semisync_master.so'
(errno: 22 libimf.so: cannot open shared object file:
No such file or directory)
```

You can obtain `libimf` from <https://dev.mysql.com/downloads/os-linux.html>.

To see which plugins are installed, use the `SHOW PLUGINS` statement, or query the `INFORMATION_SCHEMA.PLUGINS` table.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.5.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
 FROM INFORMATION_SCHEMA.PLUGINS
 WHERE PLUGIN_NAME LIKE '%semi%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| rpl_semi_sync_master | ACTIVE |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the source side and the replica side to enable semisynchronous replication. If only one side is enabled, replication is asynchronous.

To control whether an installed plugin is enabled, set the appropriate system variables. You can set these variables at runtime using `SET GLOBAL`, or at server startup on the command line or in an option file.

At runtime, these source-side system variables are available:

```
SET GLOBAL rpl_semi_sync_master_enabled = {0|1};
SET GLOBAL rpl_semi_sync_master_timeout = N;
```

On the replica side, this system variable is available:

```
SET GLOBAL rpl_semi_sync_slave_enabled = {0|1};
```

For `rpl_semi_sync_master_enabled` or `rpl_semi_sync_slave_enabled`, the value should be 1 to enable semisynchronous replication or 0 to disable it. By default, these variables are set to 0.

For `rpl_semi_sync_master_timeout`, the value `N` is given in milliseconds. The default value is 10000 (10 seconds).

If you enable semisynchronous replication on a replica at runtime, you must also start the replication I/O thread (stopping it first if it is already running) to cause the replica to connect to the source and register as a semisynchronous replica:

```
STOP SLAVE IO_THREAD;
START SLAVE IO_THREAD;
```

If the replication I/O thread is already running and you do not restart it, the replica continues to use asynchronous replication.

At server startup, the variables that control semisynchronous replication can be set as command-line options or in an option file. A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the source and replica sides as follows.

On the source:

```
[mysqld]
rpl_semi_sync_master_enabled=1
rpl_semi_sync_master_timeout=1000 # 1 second
```

On each replica:

```
[mysqld]
rpl_semi_sync_slave_enabled=1
```

### 16.3.9.3 Semisynchronous Replication Monitoring

The plugins for the semisynchronous replication capability expose several system and status variables that you can examine to determine its configuration and operational state.

The system variable reflect how semisynchronous replication is configured. To check their values, use `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'rpl_semi_sync%';
```

The status variables enable you to monitor the operation of semisynchronous replication. To check their values, use `SHOW STATUS`:

```
mysql> SHOW STATUS LIKE 'Rpl_semi_sync%';
```

When the source switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a replica catching up, it sets the value of the `Rpl_semi_sync_master_status` status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the source means that it is possible for the `rpl_semi_sync_master_enabled` system variable to have a value of 1 on the source side even when semisynchronous replication is in fact not operational at the moment. You can monitor the `Rpl_semi_sync_master_status` status variable to determine whether the source currently is using asynchronous or semisynchronous replication.

To see how many semisynchronous replicas are connected, check `Rpl_semi_sync_master_clients`.

The number of commits that have been acknowledged successfully or unsuccessfully by replicas are indicated by the `Rpl_semi_sync_master_yes_tx` and `Rpl_semi_sync_master_no_tx` variables.

On the replica side, `Rpl_semi_sync_slave_status` indicates whether semisynchronous replication currently is operational.

### 16.3.10 Delayed Replication

MySQL 5.7 supports delayed replication such that a replica server deliberately lags behind the source by at least a specified amount of time. The default delay is 0 seconds. Use the `MASTER_DELAY` option for `CHANGE MASTER TO` to set the delay to `N` seconds:

```
CHANGE MASTER TO MASTER_DELAY = N;
```

An event received from the source is not executed until at least `N` seconds later than its execution on the source. The exceptions are that there is no delay for format description events or log file rotation events, which affect only the internal state of the SQL thread.

Delayed replication can be used for several purposes:

- To protect against user mistakes on the source. A DBA can roll back a delayed replica to the time just before the disaster.
- To test how the system behaves when there is a lag. For example, in an application, a lag might be caused by a heavy load on the replica. However, it can be difficult to generate this load level. Delayed replication can simulate the lag without having to simulate the load. It can also be used to debug conditions related to a lagging replica.
- To inspect what the database looked like long ago, without having to reload a backup. For example, if the delay is one week and the DBA needs to see what the database looked like before the last few days' worth of development, the delayed replica can be inspected.

`START SLAVE` and `STOP SLAVE` take effect immediately and ignore any delay. `RESET SLAVE` resets the delay to 0.

`SHOW SLAVE STATUS` has three fields that provide information about the delay:

- `SQL_Delay`: A nonnegative integer indicating the number of seconds that the replica must lag the source.
- `SQL_Remaining_Delay`: When `Slave_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after master executed event`, this field contains an integer indicating the number of seconds left of the delay. At other times, this field is `NULL`.
- `Slave_SQL_Running_State`: A string indicating the state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`.

When the replication SQL thread is waiting for the delay to elapse before executing an event, `SHOW PROCESSLIST` displays its `State` value as `Waiting until MASTER_DELAY seconds after master executed event`.

## 16.4 Replication Notes and Tips

### 16.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the source and replica. In other words, successful statement-based replication requires that any SQL features used be supported by both the source and the replica servers. If you use a feature on the source server that is available only in the current version of MySQL, you cannot replicate to a replica that uses an earlier version of MySQL. Such incompatibilities can also occur within a release series as well as between versions.

If you are planning to use statement-based replication between MySQL 5.7 and a previous MySQL release series, it is a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see [Section 23.7, “Stored Program Binary Logging”](#). For more information about

row-based logging and row-based replication, see [Section 5.4.4.1, “Binary Logging Formats”](#), and [Section 16.2.1, “Replication Formats”](#).

For additional information specific to replication and [InnoDB](#), see [Section 14.20, “InnoDB and MySQL Replication”](#). For information relating to replication with NDB Cluster, see [Section 21.6, “NDB Cluster Replication”](#).

### 16.4.1.1 Replication and AUTO\_INCREMENT

Statement-based replication of [AUTO\\_INCREMENT](#), [LAST\\_INSERT\\_ID\(\)](#), and [TIMESTAMP](#) values is done correctly, subject to the following exceptions:

- When using statement-based replication prior to MySQL 5.7.1, [AUTO\\_INCREMENT](#) columns in tables on the replica must match the same columns on the source; that is, [AUTO\\_INCREMENT](#) columns must be replicated to [AUTO\\_INCREMENT](#) columns.
- A statement invoking a trigger or function that causes an update to an [AUTO\\_INCREMENT](#) column is not replicated correctly using statement-based replication. These statements are marked as unsafe. (Bug #45677)
- An [INSERT](#) into a table that has a composite primary key that includes an [AUTO\\_INCREMENT](#) column that is not the first column of this composite key is not safe for statement-based logging or replication. These statements are marked as unsafe. (Bug #11754117, Bug #45670)

This issue does not affect tables using the [InnoDB](#) storage engine, since an [InnoDB](#) table with an [AUTO\\_INCREMENT](#) column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an [AUTO\\_INCREMENT](#) column to a table with [ALTER TABLE](#) might not produce the same ordering of the rows on the replica and the source. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the source and replica, the rows must be ordered before assigning an [AUTO\\_INCREMENT](#) number. Assuming that you want to add an [AUTO\\_INCREMENT](#) column to a table [t1](#) that has columns [col1](#) and [col2](#), the following statements produce a new table [t2](#) identical to [t1](#) but with an [AUTO\\_INCREMENT](#) column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

#### Important

To guarantee the same ordering on both source and replica, the [ORDER BY](#) clause must name *all* columns of [t1](#).

The instructions just given are subject to the limitations of [CREATE TABLE ... LIKE](#): Foreign key definitions are ignored, as are the [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) table options. If a table definition includes any of those characteristics, create [t2](#) using a [CREATE TABLE](#) statement that is identical to the one used to create [t1](#), but with the addition of the [AUTO\\_INCREMENT](#) column.

Regardless of the method used to create and populate the copy having the [AUTO\\_INCREMENT](#) column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section B.3.6.1, “Problems with ALTER TABLE”](#).

### 16.4.1.2 Replication and BLACKHOLE Tables

The [BLACKHOLE](#) storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use.

Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting `BLACKHOLE` tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped—they are not written to the binary log. A warning is logged whenever this occurs (Bug #13004581).

For this reason we recommend when you replicate to tables using the `BLACKHOLE` storage engine that you have the `binlog_format` server variable set to `STATEMENT`, and not to either `ROW` or `MIXED`.

#### 16.4.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the source has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

#### 16.4.1.4 Replication and CHECKSUM TABLE

`CHECKSUM TABLE` returns a checksum that is calculated row by row, using a method that depends on the table row storage format. The storage format is not guaranteed to remain the same between MySQL versions, so the checksum value might change following an upgrade.

#### 16.4.1.5 Replication of CREATE ... IF NOT EXISTS Statements

MySQL applies these rules when various `CREATE ... IF NOT EXISTS` statements are replicated:

- Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the source.
- Similarly, every `CREATE TABLE IF NOT EXISTS` statement without a `SELECT` is replicated, whether or not the table already exists on the source. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. Replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see [Section 16.4.1.6, “Replication of CREATE TABLE ... SELECT Statements”](#), for more information.
- `CREATE EVENT IF NOT EXISTS` is always replicated, whether or not the event named in the statement already exists on the source.

#### 16.4.1.6 Replication of CREATE TABLE ... SELECT Statements

This section discusses how MySQL replicates `CREATE TABLE ... SELECT` statements.

MySQL 5.7 does not allow a `CREATE TABLE ... SELECT` statement to make any changes in tables other than the table that is created by the statement. Some older versions of MySQL permitted these statements to do so; this means that, when using replication between a MySQL 5.6 or later replica and a source running a previous version of MySQL, a `CREATE TABLE ... SELECT` statement causing changes in other tables on the source fails on the replica, causing replication to stop. To prevent this from happening, you should use row-based replication, rewrite the offending statement before running it on the source, or upgrade the source to MySQL 5.7. (If you choose to upgrade the source, keep in mind that such a `CREATE TABLE ... SELECT` statement fails following the upgrade unless it is rewritten to remove any side effects on other tables.)

These behaviors are not dependent on MySQL version:

- `CREATE TABLE ... SELECT` always performs an implicit commit ([Section 13.3.3, “Statements That Cause an Implicit Commit”](#)).
- If destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.

- `STATEMENT` or `MIXED` format: The statement is logged as written.
- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.
- If the statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

When the destination table exists and `IF NOT EXISTS` is given, MySQL 5.7 ignores the statement completely; nothing is inserted or logged.

#### 16.4.1.7 Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

The statements `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` are not written to the binary log, regardless of the binary logging format that is in use.

#### 16.4.1.8 Replication of CURRENT\_USER()

The following statements support use of the `CURRENT_USER()` function to take the place of the name of, and possibly the host for, an affected user or a definer:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

When binary logging is enabled and `CURRENT_USER()` or `CURRENT_USER` is used as the definer in any of these statements, MySQL Server ensures that the statement is applied to the same user on both the source and the replica when the statement is replicated. In some cases, such as statements that change passwords, the function reference is expanded before it is written to the binary log, so that the statement includes the user name. For all other cases, the name of the current user on the source is replicated to the replica as metadata, and the replica applies the statement to the current user named in the metadata, rather than to the current user on the replica.

#### 16.4.1.9 Replication of DROP ... IF EXISTS Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the source. This is to ensure that the object to be dropped no longer exists on either the source or the replica, once the replica has caught up with the source.

`DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the source.

### 16.4.1.10 Replication with Differing Table Definitions on Source and Replica

Source and target tables for replication do not have to be identical. A table on the source can have more or fewer columns than the replica's copy of the table. In addition, corresponding table columns on the source and the replica can use different data types, subject to certain conditions.

#### Note

Replication between tables which are partitioned differently from one another is not supported. See [Section 16.4.1.23, “Replication and Partitioning”](#).

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the source and the replica. Additional conditions are discussed, with examples, in the following two sections.

#### Replication with More Columns on Source or Replica

You can replicate a table from the source to the replica such that the source and replica copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the source and the replica.  
(This is true even if both tables have the same number of columns.)
- Columns common to both versions of the table must be defined before any additional columns.

This means that executing an `ALTER TABLE` statement on the replica where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

Suppose that a table `t`, existing on the source and the replica, is defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (
 c1 INT,
 c2 INT,
 c3 INT
);
```

Suppose that the `ALTER TABLE` statement shown here is executed on the replica:

```
ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
```

The previous `ALTER TABLE` is permitted on the replica because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the replica without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
```

Replication fails after execution on the replica of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see [Section 11.6, “Data Type Default Values”](#).

In addition, when the replica's copy of the table has more columns than the source's copy, each column common to the tables must use the same data type in both tables.

**Examples.** The following examples illustrate some valid and invalid table definitions:

**More columns on the source.** The following table definitions are valid and replicate correctly:

```
source> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
replica> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the replica than they are on the source:

```
source> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
replica> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the source appears before the definitions of the columns common to both versions of the table:

```
source> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
replica> CREATE TABLE t1 (c1 INT, c2 INT);
```

**More columns on the replica.** The following table definitions are valid and replicate correctly:

```
source> CREATE TABLE t1 (c1 INT, c2 INT);
replica> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the source and the replica:

```
source> CREATE TABLE t1 (c1 INT, c2 INT);
replica> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the replica's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
source> CREATE TABLE t1 (c1 INT, c2 INT);
replica> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the replica's version of the table has additional columns compared to the source's version, and the two versions of the table use different data types for the common column `c2`:

```
source> CREATE TABLE t1 (c1 INT, c2 BIGINT);
replica> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

## Replication of Columns Having Different Data Types

Corresponding columns on the source's and the replica's copies of the same table ideally should have the same data type. However, this is not always strictly enforced, as long as certain conditions are met.

It is usually possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it is also possible to replicate from a column having one data type (on the source) to a column having a different data type (on the replica); when the data type of the source's version of the column is promoted to a type that is the same size or larger on the replica, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the source or the replica. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

**Important**

Whether you use statement-based or row-based replication, the replica's copy of the table cannot contain more columns than the source's copy if you wish to employ attribute promotion.

**Statement-based replication.** When using statement-based replication, a simple rule of thumb to follow is, “If the statement run on the source would also execute successfully on the replica, it should also replicate successfully”. In other words, if the statement uses a value that is compatible with the type of a given column on the replica, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the replica's copy of a table to `BIGINT`, any insert into that column on the source that succeeds should also succeed on the replica, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

Prior to MySQL 5.7.1, when using statement-based replication, `AUTO_INCREMENT` columns were required to be the same on both the source and the replica; otherwise, updates could be applied to the wrong table on the replica. (Bug #12669186)

**Row-based replication: attribute promotion and demotion.** Row-based replication supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

**Lossy and non-lossy conversions.** In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a “fit” in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy* conversion.

**Type conversion modes (`slave_type_conversions` variable).** The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the replica. This variable takes a set of values from the following table, which shows the effects of each mode on the replica's type-conversion behavior:

| Mode                                  | Effect                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ALL_LOSSY</code>                | <p>In this mode, type conversions that would mean loss of information are permitted.</p> <p>This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling <i>only</i> this mode permits an <code>INT</code> column to be converted to <code>TINYINT</code> (a lossy conversion), but not a <code>TINYINT</code> column to an <code>INT</code> column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the replica.</p>                                                       |
| <code>ALL_NON_LOSSY</code>            | <p>This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type.</p> <p>Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the <code>ALL_LOSSY</code> mode. If only <code>ALL_NON_LOSSY</code> is set, but not <code>ALL_LOSSY</code>, then attempting a conversion that would result in the loss of data (such as <code>INT</code> to <code>TINYINT</code>, or <code>CHAR(25)</code> to <code>VARCHAR(20)</code>) causes the replica to stop with an error.</p> |
| <code>ALL_LOSSY, ALL_NON_LOSSY</code> | When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Mode                                  | Effect                                                                                                                                                                                                                               |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ALL_SIGNED</code>               | Treat promoted integer types as signed values (the default behavior).                                                                                                                                                                |
| <code>ALL_UNSIGNED</code>             | Treat promoted integer types as unsigned values.                                                                                                                                                                                     |
| <code>ALL_SIGNED, ALL_UNSIGNED</code> | Treat promoted integer types as signed if possible, otherwise as unsigned.                                                                                                                                                           |
| [empty]                               | <p>When <code>slave_type_conversions</code> is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types.</p> <p>This mode is the default.</p> |

When an integer type is promoted, its signedness is not preserved. By default, the replica treats all such values as signed. Beginning with MySQL 5.7.2, you can control this behavior using `ALL_SIGNED`, `ALL_UNSIGNED`, or both. (Bug#15831300) `ALL_SIGNED` tells the replica to treat all promoted integer types as signed; `ALL_UNSIGNED` instructs it to treat these as unsigned. Specifying both causes the replica to treat the value as signed if possible, otherwise to treat it as unsigned; the order in which they are listed is not significant. Neither `ALL_SIGNED` nor `ALL_UNSIGNED` has any effect if at least one of `ALL_LOSSY` or `ALL_NONLOSSY` is not also used.

Changing the type conversion mode requires restarting the replica with the new `slave_type_conversions` setting.

**Supported conversions.** Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

This includes conversions between the signed and unsigned versions of these types.

Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For ensuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

`FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where  $D' \geq D$  and  $(M'-D') \geq (M-D)$  is non-lossy; for any case where  $M' < M$ ,  $D' < D$ , or both, only a lossy conversion can be made.

For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See [Section 12.22.4, “Rounding Behavior”](#), for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first `N` characters of the string on the replica, where `N` is the width of the target column.

### Important

Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first  $N$  bytes of the string on the replica, where  $N$  is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where  $M' > M$ , the most significant bits of the `BIT(M')` columns are cleared (set to zero) and the  $M$  bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where  $M' < M$ , the maximum possible value for the `BIT(M')` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

#### 16.4.1.11 Replication and DIRECTORY Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the source server, the table option is also used on the replica. This can cause problems if no corresponding directory exists in the replica host's file system or if it exists but is not accessible to the replica server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the replica, which causes the replica to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see [Section 5.1.10, “Server SQL Modes”](#).

#### 16.4.1.12 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on source and replica servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See [Section 12.3, “Type Conversion in Expression Evaluation”](#), and [Section B.3.4.8, “Problems with Floating-Point Values”](#).

#### 16.4.1.13 Replication and Fractional Seconds Support

MySQL 5.7 permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. See [Section 11.2.7, “Fractional Seconds in Time Values”](#).

There may be problems replicating from a source server that understands fractional seconds to an older replica (MySQL 5.6.3 and earlier) that does not:

- For `CREATE TABLE` statements containing columns that have an `fsp` (fractional seconds precision) value greater than 0, replication fails due to parser errors.
- Statements that use temporal data types with an `fsp` value of 0 work with statement-based logging but not row-based logging. In the latter case, the data types have binary formats and type codes on the source that differ from those on the replica.
- Some expression results differ on source and replica. Examples: On the source, the `timestamp` system variable returns a value that includes a microseconds fractional part; on the replica, it returns an integer. On the source, functions that return a result that includes the current time (such as `CURTIME()`, `SYSDATE()`, or `UTC_TIMESTAMP()`) interpret an argument as an `fsp` value and the return value includes a fractional seconds part of that many digits. On the replica, these functions permit an argument but ignore it.

### 16.4.1.14 Replication and FLUSH

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a replica: `FLUSH LOGS` and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see [Section 13.7.6.3, “FLUSH Statement”](#). The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to replicas. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the replicas to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the replicas. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

### 16.4.1.15 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UUID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the replica unless row-based replication is enabled. (See [Section 16.2.1, “Replication Formats”](#).)

`USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (See also [Section 16.4.1.8, “Replication of CURRENT\\_USER\(\)”](#).) This is also true for `VERSION()` and `RAND()`.

- For `NOW()`, the binary log includes the timestamp. This means that the value *as returned by the call to this function on the source* is replicated to the replica. To avoid unexpected results when replicating between MySQL servers in different time zones, set the time zone on both source and replica. For more information, see [Section 16.4.1.31, “Replication and Time Zones”](#).

To explain the potential problems when replicating between servers which are in different time zones, suppose that the source is located in New York, the replica is located in Stockholm, and both servers are using local time. Suppose further that, on the source, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES (NOW());
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the replica at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the replica's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the replica's copy of `mytable`, you obtain exactly the same result as on the source:

```
mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
```

```
+-----+
1 row in set (0.00 sec)
```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the source and the replica to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the source and the replica.

`SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode.

See also [Section 16.4.1.31, “Replication and Time Zones”](#).

- *The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the replica knowing the concurrency context on the source. Therefore, these functions should not be used to insert into a source table because the content on the replica would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...))`.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode.

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the source and replica.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(FOUND_ROWS());
```

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the replica correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

Prior to MySQL 5.7.3, the value of `LAST_INSERT_ID()` was not replicated correctly if any filtering options such as `--replicate-ignore-db` and `--replicate-do-table` were enabled on the replica. (Bug #17234370, BUG# 69861)

#### 16.4.1.16 Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
  - `CREATE EVENT`
  - `ALTER EVENT`
  - `DROP EVENT`
  - `CREATE PROCEDURE`
  - `DROP PROCEDURE`
  - `CREATE FUNCTION`
  - `DROP FUNCTION`
  - `CREATE TRIGGER`
  - `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

##### Note

Attempting to replicate invoked features using statement-based replication produces the warning `Statement is not safe to log in statement format`. For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
- The status of the event is set to `SLAVESIDE_DISABLED` on the replica regardless of the state specified (this does not apply to `DROP EVENT`).

- The source on which the event was created is identified on the replica by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` store this information. See [Section 24.3.8, “The INFORMATION\\_SCHEMA EVENTS Table”](#), and [Section 13.7.5.18, “SHOW EVENTS Statement”](#), for more information.
- The feature implementation resides on the replica in a renewable state so that if the source fails, the replica can be used as the source without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication source server), query the `INFORMATION_SCHEMA.EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
 FROM INFORMATION_SCHEMA.EVENTS
 WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
 WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replica having such events to a replication source server, you must enable each event using `ALTER EVENT event_name ENABLE`, where `event_name` is the name of the event.

If more than one source was involved in creating events on this replica, and you wish to identify events that were created only on a given source having the server ID `source_id`, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
 FROM INFORMATION_SCHEMA.EVENTS
 WHERE STATUS = 'SLAVESIDE_DISABLED'
 AND ORIGINATOR = 'source_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
 WHERE STATUS = 'SLAVESIDE_DISABLED'
 AND ORIGINATOR = 'source_id'
```

Before enabling events that were replicated from the source, you should disable the MySQL Event Scheduler on the replica (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the replica afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`)-

If you later demote the new source back to being a replica, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replica, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
 FROM INFORMATION_SCHEMA.EVENTS
 WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

#### 16.4.1.17 Replication and LIMIT

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

When using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

#### 16.4.1.18 Replication and LOAD DATA

`LOAD DATA` is considered unsafe for statement-based logging (see [Section 16.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#)). When `binlog_format=MIXED` is set, the statement is logged in row-based format. When `binlog_format=STATEMENT` is set, note that `LOAD DATA` does not generate a warning, unlike other unsafe statements.

When `mysqlbinlog` reads log events for `LOAD DATA` statements logged in statement-based format, a generated local file is created in a temporary directory. These temporary files are not automatically removed by `mysqlbinlog` or any other MySQL program. If you do use `LOAD DATA` statements with statement-based binary logging, you should delete the temporary files yourself after you no longer need the statement log. For more information, see [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

#### 16.4.1.19 Replication and max\_allowed\_packet

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replicas. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the source, the source fails with an error, and the replica shuts down the replication I/O thread. If `max_allowed_packet` is too small on the replica, this also causes the replica to stop the replication I/O thread.

Row-based replication currently sends all columns and column values for updated rows from the source to the replica, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

#### 16.4.1.20 Replication and MEMORY Tables

When a replication source server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to replicas, the first time that the source uses a given `MEMORY` table after startup, it logs an event that notifies replicas that the table must be emptied by writing a `DELETE` or (from MySQL 5.7.32) `TRUNCATE TABLE` statement for that table to the binary log. This generated event is identifiable by a comment in the binary log, and if GTIDs are in use on the server, it has a GTID assigned. The statement is always logged in statement format, even if the binary logging format is set to `ROW`, and it is written even if `read_only` or `super_read_only` mode is set on the server. Note that the replica still has outdated data in a `MEMORY` table during the interval between the source's restart and its first use of the table. To avoid this interval when a direct query to the replica could return stale data, you can set the `init_file` system variable to name a file containing statements that populate the `MEMORY` table on the source at startup.

When a replica server shuts down and restarts, its `MEMORY` tables become empty. This causes the replica to be out of synchrony with the source and may lead to other failures or cause the replica to stop:

- Row-format updates and deletes received from the source may fail with `Can't find record in 'memory_table'`.
- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the source and replica.

The replica also writes a `DELETE` or (from MySQL 5.7.32) `TRUNCATE TABLE` statement to its own binary log, which is passed on to any downstream replicas, causing them to empty their own `MEMORY` tables.

The safe way to restart a replica that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the source and wait until those changes have replicated to the replica. Then it is safe to restart the replica.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the replica from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the replica again. This allows the replica to continue to replicate, but its `MEMORY` tables still differ from those on the source. This is acceptable if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

(The method just described is not applicable in NDB Cluster, where `slave_exec_mode` is always `IDEMPOTENT`, and cannot be changed.)

The size of `MEMORY` tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see [Section 16.4.1.37, “Replication and Variables”](#)). A change in `max_heap_table_size` takes effect for `MEMORY` tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all `MEMORY` tables following a server restart. If you increase the value of this variable on the source without doing so on the replica, it becomes possible for a table on the source to grow larger than its counterpart on the replica, leading to inserts that succeed on the source but fail on the replica with `Table is full` errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the replica as well as on the source, then restart replication. It is also recommended that you restart both the source and replica MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See [Section 15.3, “The MEMORY Storage Engine”](#), for more information about `MEMORY` tables.

#### 16.4.1.21 Replication of the mysql System Database

Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to replicas using statement-based replication.

#### 16.4.1.22 Replication and the Query Optimizer

It is possible for the data on the source and replica to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see [Section 16.4.1.17, “Replication and LIMIT”](#), for a detailed discussion of these.

#### 16.4.1.23 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure except where an exception is specifically allowed (see [Section 16.4.1.10, “Replication with Differing Table Definitions on Source and Replica”](#)).

Replication between tables having different partitioning is generally not supported. This because statements (such as `ALTER TABLE ... DROP PARTITION`) acting directly on partitions in such cases may produce different results on source and replica. In the case where a table is partitioned on the source but not on the replica, any statements operating on partitions on the source's copy of the replica fail on the replica. When the replica's copy of the table is partitioned but the source's copy is not, statements acting on partitions cannot be run on the source without causing errors there.

Due to these dangers of causing replication to fail entirely (on account of failed statements) and of inconsistencies (when the result of a partition-level SQL statement produces different results on source and replica), we recommend that insure that the partitioning of any tables to be replicated from the source is matched by the replica's versions of these tables.

#### 16.4.1.24 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause source and replica to lose synchronization. For this reason, in the event that a table on the source becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the source's and replica's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

#### 16.4.1.25 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older source to a newer replica and you make use of identifiers on the source that are reserved words in the newer MySQL version running on the replica. An example of this is using a table column named `virtual` on a 5.6 source that is replicating to a 5.7 or higher replica because `VIRTUAL` is a reserved word beginning in MySQL 5.7. Replication can fail in such cases with Error 1064 `You have an error in your SQL syntax... even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication.` This is due to the fact that each SQL event must be parsed by the replica prior to execution, so that the replica knows which database object or objects would be affected; only after the event is parsed can the replica apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the source which would be regarded as reserved words by the replica, do one of the following:

- Use one or more `ALTER TABLE` statements on the source to change the names of any database objects where these names would be considered reserved words on the replica, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (`).

For listings of reserved words by MySQL version, see [Keywords and Reserved Words in MySQL 5.7](#), in the *MySQL Server Version Reference*. For identifier quoting rules, see [Section 9.2, “Schema Object Names”](#).

#### 16.4.1.26 Replication and Source or Replica Shutdowns

It is safe to shut down a source server and restart it later. When a replica loses its connection to the source, the replica tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement. A replica also is able to deal with network connectivity outages. However, the replica notices the network outage only after receiving no data from the source for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See [Section 16.3.2, “Handling an Unexpected Halt of a Replica”](#).

An unclean shutdown (for example, a crash) on the source side can result in the source's binary log having a final position less than the most recent position read by the replica, due to the source's binary log file not being flushed. This can cause the replica not to be able to replicate when the source comes back up. Setting `sync_binlog=1` in the source's `my.cnf` file helps to minimize this problem because it causes the source to flush its binary log more frequently. For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should also set `innodb_flush_log_at_trx_commit=1`. With this setting, the contents of the `InnoDB` redo log

buffer are written out to the log file at each transaction commit and the log file is flushed to disk. Note that the durability of transactions is still not guaranteed with this setting, because operating systems or disk hardware may tell `mysqld` that the flush-to-disk operation has taken place, even though it has not.

Shutting down a replica cleanly is safe because it keeps track of where it left off. However, be careful that the replica does not have temporary tables open; see [Section 16.4.1.29, “Replication and Temporary Tables”](#). Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the replica commits and then updates `relay-log.info`. If an unexpected exit occurs between these two operations, relay log processing proceeds further than the information file indicates and the replica re-executes the events from the last transaction in the relay log after it has been restarted.
- A similar problem can occur if the replica updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set `sync_relay_log_info=1` in the replica `my.cnf` file. Setting `sync_relay_log_info` to 0 causes no writes to be forced to disk and the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

#### 16.4.1.27 Replica Errors During Replication

If a statement produces the same error (identical error code) on both the source and the replica, the error is logged, but replication continues.

If a statement produces different errors on the source and the replica, the replication SQL thread terminates, and the replica writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the source or the replica, but not both. To address the issue, connect to the replica manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the replica again.

##### Note

If a temporary error is recorded in the replica's error log, you do not necessarily have to take any action suggested in the quoted error message. Temporary errors should be handled by the client retrying the transaction. For example, if the replication SQL thread records a temporary error relating to a deadlock, you do not need to restart the transaction manually on the replica, unless the replication SQL thread subsequently terminates with a nontemporary error message.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the source, the replica expects execution of the statement to result in the same error code. If it does not, the replication SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the source and replica, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since `MyISAM` ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an `InnoDB` table on the source might cause a foreign key violation but the same statement performed

on a [MyISAM](#) version of the same table on the replica would produce no such error, causing replication to stop.

#### 16.4.1.28 Replication and Server SQL Mode

Using different server SQL mode settings on the source and the replica may cause the same [INSERT](#) statements to be handled differently on the source and the replica, leading the source and replica to diverge. For best results, you should always use the same server SQL mode on the source and on the replica. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the source and the replica is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the source's and replica's copies of a given table. It may also cause inserts into partitioned tables that succeed on the source to fail on the replica.

For more information, see [Section 5.1.10, “Server SQL Modes”](#). In particular, see [SQL Mode Changes in MySQL 5.7](#), which describes changes in MySQL 5.7, so that you can assess whether your applications are affected.

#### 16.4.1.29 Replication and Temporary Tables

The discussion in the following paragraphs does not apply when [binlog\\_format=ROW](#) because, in that case, temporary tables are not replicated; this means that there are never any temporary tables on the replica to be lost in the event of an unplanned shutdown by the replica. The remainder of this section applies only when using statement-based or mixed-format replication. Loss of replicated temporary tables on the replica can be an issue, whenever [binlog\\_format](#) is [STATEMENT](#) or [MIXED](#), for statements involving temporary tables that can be logged safely using statement-based format. For more information about row-based replication and temporary tables, see [Row-based logging of temporary tables](#).

**Safe replica shutdown when using temporary tables.** Temporary tables are replicated except in the case where you stop the replica server (not just the replication threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the replica. If you stop the replica server, the temporary tables needed by those updates are no longer available when the replica is restarted. To avoid this problem, do not shut down the replica while it has temporary tables open. Instead, use the following procedure:

1. Issue a [STOP SLAVE SQL THREAD](#) statement.
2. Use [SHOW STATUS](#) to check the value of the [Slave\\_open\\_temp\\_tables](#) variable.
3. If the value is not 0, restart the replication SQL thread with [START SLAVE SQL THREAD](#) and repeat the procedure later.
4. When the value is 0, issue a [mysqladmin shutdown](#) command to stop the replica.

**Temporary tables and replication options.** By default, all temporary tables are replicated; this happens whether or not there are any matching [--replicate-do-db](#), [--replicate-do-table](#), or [--replicate-wild-do-table](#) options in effect. However, the [--replicate-ignore-table](#) and [--replicate-wild-ignore-table](#) options are honored for temporary tables. The exception is that to enable correct removal of temporary tables at the end of a session, a replica always replicates a [DROP TEMPORARY TABLE IF EXISTS](#) statement, regardless of any exclusion rules that would normally apply for the specified table.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a [--replicate-wild-ignore-table](#) option to match that prefix. For example, you might give all such tables names beginning with [norep](#) (such as [norepmytable](#), [norepyourtable](#), and so on), then use [--replicate-wild-ignore-table=norep%](#) to prevent them from being replicated.

#### 16.4.1.30 Replication Retries and Timeouts

The global system variable `slave_transaction_retries` affects replication as follows: If the replication SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because it exceeded the `InnoDB innodb_lock_wait_timeout` value, or the `NDB TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout` value, the replica automatically retries the transaction `slave_transaction_retries` times before stopping with an error. The default value is 10. The total retry count can be seen in the output of `SHOW STATUS`; see [Section 5.1.9, “Server Status Variables”](#).

#### 16.4.1.31 Replication and Time Zones

By default, source and replica servers assume that they are in the same time zone. If you are replicating between servers in different time zones, the time zone must be set on both source and replica. Otherwise, statements depending on the local time on the source are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions.

Verify that your combination of settings for the system time zone (`system_time_zone`), server current time zone (the global value of `time_zone`), and per-session time zones (the session value of `time_zone`) on the source and replica is producing the correct results. In particular, if the `time_zone` system variable is set to the value `SYSTEM`, indicating that the server time zone is the same as the system time zone, this can cause the source and replica to apply different time zones. For example, a source could write the following statement in the binary log:

```
SET @@session.time_zone='SYSTEM';
```

If this source and its replica have a different setting for their system time zones, this statement can produce unexpected results on the replica, even if the replica's global `time_zone` value has been set to match the source's. For an explanation of MySQL Server's time zone settings, and how to change them, see [Section 5.1.13, “MySQL Server Time Zone Support”](#).

See also [Section 16.4.1.15, “Replication and System Functions”](#).

#### 16.4.1.32 Replication and Transaction Inconsistencies

Inconsistencies in the sequence of transactions that have been executed from the relay log can occur depending on your replication configuration. This section explains how to avoid inconsistencies and solve any problems they cause.

The following types of inconsistencies can exist:

- *Half-applied transactions*. A transaction which updates non-transactional tables has applied some but not all of its changes.
- *Gaps*. A gap is a transaction that has not been fully applied, even though some transaction later in the sequence has been applied. Gaps can only appear when using a multithreaded replica. To avoid gaps occurring, set `slave_preserve_commit_order=1`, which requires `slave_parallel_type=LOGICAL_CLOCK`, and that `log-bin` and `log-slave-updates` are also enabled. Note that `slave_preserve_commit_order=1` does not preserve the order of non-transactional DML updates, so these might commit before transactions that precede them in the relay log, which might result in gaps.
- *Source binary log position lag*. Even in the absence of gaps, it is possible that transactions after `Exec_master_log_pos` have been applied. That is, all transactions up to point `N` have been applied, and no transactions after `N` have been applied, but `Exec_master_log_pos` has a value smaller than `N`. In this situation, `Exec_master_log_pos` is a “low-water mark” of the transactions applied, and lags behind the position of the most recently applied transaction. This can only happen on multithreaded replicas. Enabling `slave_preserve_commit_order` does not prevent source binary log position lag.

The following scenarios are relevant to the existence of half-applied transactions, gaps, and source binary log position lag:

1. While replication threads are running, there may be gaps and half-applied transactions.

2. `mysqld` shuts down. Both clean and unclean shutdown abort ongoing transactions and may leave gaps and half-applied transactions.
3. `KILL` of replication threads (the SQL thread when using a single-threaded replica, the coordinator thread when using a multithreaded replica). This aborts ongoing transactions and may leave gaps and half-applied transactions.
4. Error in applier threads. This may leave gaps. If the error is in a mixed transaction, that transaction is half-applied. When using a multithreaded replica, workers which have not received an error complete their queues, so it may take time to stop all threads.
5. `STOP SLAVE` when using a multithreaded replica. After issuing `STOP SLAVE`, the replica waits for any gaps to be filled and then updates `Exec_master_log_pos`. This ensures it never leaves gaps or source binary log position lag, unless any of the cases above applies, in other words, before `STOP SLAVE` completes, either an error happens, or another thread issues `KILL`, or the server restarts. In these cases, `STOP SLAVE` returns successfully.
6. If the last transaction in the relay log is only half-received and the multithreaded replica coordinator has started to schedule the transaction to a worker, then `STOP SLAVE` waits up to 60 seconds for the transaction to be received. After this timeout, the coordinator gives up and aborts the transaction. If the transaction is mixed, it may be left half-completed.
7. `STOP SLAVE` when using a single-threaded replica. If the ongoing transaction only updates transactional tables, it is rolled back and `STOP SLAVE` stops immediately. If the ongoing transaction is mixed, `STOP SLAVE` waits up to 60 seconds for the transaction to complete. After this timeout, it aborts the transaction, so it may be left half-completed.

The global variable `rpl_stop_slave_timeout` is unrelated to the process of stopping the replication threads. It only makes the client that issues `STOP SLAVE` return to the client, but the replication threads continue to try to stop.

If a replication channel has gaps, it has the following consequences:

1. The replica database is in a state that may never have existed on the source.
2. The field `Exec_master_log_pos` in `SHOW SLAVE STATUS` is only a “low-water mark”. In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not.
3. `CHANGE MASTER TO` statements for that channel fail with an error, unless the applier threads are running and the `CHANGE MASTER TO` statement only sets receiver options.
4. If `mysqld` is started with `--relay-log-recovery`, no recovery is done for that channel, and a warning is printed.
5. If `mysqldump` is used with `--dump-slave`, it does not record the existence of gaps; thus it prints `CHANGE MASTER TO` with `RELAY_LOG_POS` set to the “low-water mark” position in `Exec_master_log_pos`.

After applying the dump on another server, and starting the replication threads, transactions appearing after the position are replicated again. Note that this is harmless if GTIDs are enabled (however, in that case it is not recommended to use `--dump-slave`).

If a replication channel has source binary log position lag but no gaps, cases 2 to 5 above apply, but case 1 does not.

The source binary log position information is persisted in binary format in the internal table `mysql.slave_worker_info`. `START SLAVE [SQL_THREAD]` always consults this information so that it applies only the correct transactions. This remains true even if `slave_parallel_workers` has been changed to 0 before `START SLAVE`, and even if `START SLAVE` is used with `UNTIL` clauses. `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` only applies as many transactions as needed in

order to fill in the gaps. If `START SLAVE` is used with `UNTIL` clauses that tell it to stop before it has consumed all the gaps, then it leaves remaining gaps.

### Warning

`RESET SLAVE` removes the relay logs and resets the replication position. Thus issuing `RESET SLAVE` on a replica with gaps means the replica loses any information about the gaps, without correcting the gaps.

When GTID-based replication is in use, from MySQL 5.7.28 a multithreaded replica checks first whether `MASTER_AUTO_POSITION` is set to `ON`, and if it is, omits the step of calculating the transactions that should be skipped or not skipped. In that situation, the old relay logs are not required for the recovery process.

#### 16.4.1.33 Replication and Transactions

**Mixing transactional and nontransactional statements within the same transaction.** In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

The server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)
- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` system variable. When this variable is `OFF` (the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` has no effect for row-format or mixed-format binary logging.

#### Transactional, nontransactional, and mixed statements.

To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. A statement that references both nontransactional and transactional tables and updates *any* of the tables involved, is considered a “mixed” statement. (In some past MySQL versions, only a statement that updated *both* nontransactional and transactional tables was considered mixed.) Mixed statements, like transactional statements, are cached and logged when the transaction commits.

A mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a temporary table
- Reads a nontransactional table and the transaction isolation level is less than `REPEATABLE_READ`

A mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:

- Updates any table and reads from any temporary table
- Updates a nontransactional table and `binlog_direct_non_transactional_updates` is `OFF`

For more information, see [Section 16.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#).

**Note**

A mixed statement is unrelated to mixed binary logging format.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on source and replica.** It is possible to replicate transactional tables on the source using nontransactional tables on the replica. For example, you can replicate an `InnoDB` source table as a `MyISAM` replica table. However, if you do this, there are problems if the replica is stopped in the middle of a `BEGIN ... COMMIT` block because the replica restarts at the beginning of the `BEGIN` block.

It is also safe to replicate transactions from `MyISAM` tables on the source to transactional tables, such as tables that use the `InnoDB` storage engine, on the replica. In such cases, an `AUTOCOMMIT=1` statement issued on the source is replicated, thus enforcing `AUTOCOMMIT` mode on the replica.

When the storage engine type of the replica is nontransactional, transactions on the source that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the source transactional table and the replica nontransactional table. That is, such transactions can lead to source storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the source to nontransactional tables on the replicas.

**Changing the binary logging format within transactions.** The `binlog_format` and `binlog_checksum` system variables are read-only as long as a transaction is in progress.

Every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. This is even true for statements affecting tables that use a nontransactional storage engine (such as `MyISAM`).

**Note**

For restrictions that apply specifically to XA transactions, see [Section 13.3.7.3, “Restrictions on XA Transactions”](#).

#### 16.4.1.34 Replication and Triggers

With statement-based replication, triggers executed on the source also execute on the replica. With row-based replication, triggers executed on the source do not execute on the replica. Instead, the row changes on the source resulting from trigger execution are replicated and applied on the replica.

This behavior is by design. If under row-based replication the replica applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the replica, leading to different data on the source and the replica.

If you want triggers to execute on both the source and the replica, perhaps because you have different triggers on the source and replica, you must use statement-based replication. However, to enable replica-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. MySQL 5.7 marks such statements as unsafe. (Bug #45677)

A trigger can have triggers for different combinations of trigger event (`INSERT`, `UPDATE`, `DELETE`) and action time (`BEFORE`, `AFTER`), but before MySQL 5.7.2 cannot have multiple triggers that have the same trigger event and action time. MySQL 5.7.2 lifts this limitation and multiple triggers are permitted. This change has replication implications for upgrades and downgrades.

For brevity, “multiple triggers” here is shorthand for “multiple triggers that have the same trigger event and action time.”

**Upgrades.** Suppose that you upgrade an old server that does not support multiple triggers to MySQL 5.7.2 or higher. If the new server is a replication source server and has old replicas that do not support multiple triggers, an error occurs on those replicas if a trigger is created on the source for a table that already has a trigger with the same trigger event and action time. To avoid this problem, upgrade the replicas first, then upgrade the source.

**Downgrades.** If you downgrade a server that supports multiple triggers to an older version that does not, the downgrade has these effects:

- For each table that has triggers, all trigger definitions remain in the `.TRG` file for the table. However, if there are multiple triggers with the same trigger event and action time, the server executes only one of them when the trigger event occurs. For information about `.TRG` files, see the Table Trigger Storage section of the MySQL Server Doxygen documentation, available at <https://dev.mysql.com/doc/index-other.html>.
- If triggers for the table are added or dropped subsequent to the downgrade, the server rewrites the table’s `.TRG` file. The rewritten file retains only one trigger per combination of trigger event and action time; the others are lost.

To avoid these problems, modify your triggers before downgrading. For each table that has multiple triggers per combination of trigger event and action time, convert each such set of triggers to a single trigger as follows:

1. For each trigger, create a stored routine that contains all the code in the trigger. Values accessed using `NEW` and `OLD` can be passed to the routine using parameters. If the trigger needs a single result value from the code, you can put the code in a stored function and have the function return the value. If the trigger needs multiple result values from the code, you can put the code in a stored procedure and return the values using `OUT` parameters.
2. Drop all triggers for the table.
3. Create one new trigger for the table that invokes the stored routines just created. The effect for this trigger is thus the same as the multiple triggers it replaces.

#### 16.4.1.35 Replication and TRUNCATE TABLE

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

`TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replicas still follow the rules described in Section 13.1.34, “`TRUNCATE TABLE Statement`” governing such tables. (Bug #36763)

#### 16.4.1.36 Replication and User Name Length

The maximum length of MySQL user names was increased from 16 characters to 32 characters in MySQL 5.7.8. Replication of user names longer than 16 characters to a replica that supports only shorter user names fails. However, this should occur only when replicating from a newer source to an older replica, which is not a recommended configuration.

### 16.4.1.37 Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See [Section 5.4.4.3, “Mixed Binary Logging Format”](#).

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the replica always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the source. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full `mode` value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `default_storage_engine` and `storage_engine` system variables are not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the source without doing so on the replica can lead eventually to `Table is full` errors on the replica when trying to execute `INSERT` statements on a `MEMORY` table on the source that is thus permitted

to grow larger than its counterpart on the replica. For more information, see [Section 16.4.1.20, “Replication and MEMORY Tables”](#).

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements do not insert the same data on the source and the replica:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=... ;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See [Section 16.2.1, “Replication Formats”](#).

The following session variables are written to the binary log and honored by the replica when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

#### Important

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

To help reduce possible confusion, we recommend that you always use the same setting for the `lower_case_table_names` system variable on both source and replica, especially when you are running MySQL on platforms with case-sensitive file systems.

### 16.4.1.38 Replication and Views

Views are always replicated to replicas. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the replica even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a same-named view is supported using statement-based logging, but not when using row-based logging. Trying to do so when row-based logging is in effect causes an error. (Bug #11752707, Bug #43975)

## 16.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one release series to the next higher release series. For example, you can replicate from a source running MySQL 5.6 to a replica running MySQL 5.7, from a source

running MySQL 5.7 to a replica running MySQL 8.0, and so on. However, you may encounter difficulties when replicating from an older source to a newer replica if the source uses statements or relies on behavior no longer supported in the version of MySQL used on the replica. For example, foreign key names longer than 64 characters are no longer supported from MySQL 8.0.

The use of more than two MySQL Server versions is not supported in replication setups involving multiple sources, regardless of the number of source or replica MySQL servers. This restriction applies not only to release series, but to version numbers within the same release series as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.7.22, MySQL 5.7.23, and MySQL 5.7.24 concurrently, although you could use any two of these releases together.

#### Important

It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade sources and replicas that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

Replication from newer sources to older replicas may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible.

This also has significant implications for upgrading replication servers; see [Section 16.4.3, “Upgrading a Replication Setup”](#), for more information.

- For more information about row-based replication, see [Section 16.2.1, “Replication Formats”](#).
- **SQL incompatibilities.** You cannot replicate from a newer source to an older replica using statement-based replication if the statements to be replicated use SQL features available on the source but not on the replica.

However, if both the source and the replica support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the source but not on the replica, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the source is not supported on the replica.

For more information on potential replication issues, see [Section 16.4.1, “Replication Features and Issues”](#).

### 16.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading. This section provides information about how upgrading affects replication. For general information about upgrading MySQL, see [Section 2.11, “Upgrading MySQL”](#).

When you upgrade a source to 5.7 from an earlier MySQL release series, you should first ensure that all the replicas of this source are using the same 5.7.x release. If this is not the case, you should first upgrade the replicas. To upgrade each replica, shut it down, upgrade it to the appropriate 5.7.x version, restart it, and restart replication. Relay logs created by the replica after the upgrade are in 5.7 format.

Changes affecting operations in strict SQL mode (`STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES`) may result in replication failure on an updated replica. For example, as of MySQL 5.7.2, the server restricts insertion of a `DEFAULT` value of 0 for temporal data types in strict mode. If you use statement-based logging (`binlog_format=STATEMENT`), if a replica is upgraded before the source, the source that is not upgraded executes statements without error that may fail on the replica and replication stops. To deal with this, stop all new statements on the source and wait until the replicas catch up. Then upgrade the replicas. Alternatively, if you cannot stop new statements, temporarily change to

row-based logging on the source (`binlog_format=ROW`) and wait until all replicas have processed all binary logs produced up to the point of this change. Then upgrade the replicas.

After the replicas have been upgraded, shut down the source, upgrade it to the same 5.7.x release as the replicas, and restart it. If you had temporarily changed the source to row-based logging, change it back to statement-based logging. The 5.7 source is able to read the old binary logs written prior to the upgrade and to send them to the 5.7 replicas. The replicas recognize the old format and handle it properly. Binary logs created by the source subsequent to the upgrade are in 5.7 format. These too are recognized by the 5.7 replicas.

In other words, when upgrading to MySQL 5.7, the replicas must be MySQL 5.7 before you can upgrade the source to 5.7. Note that downgrading from 5.7 to older versions does not work so simply: You must ensure that any 5.7 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, are detailed at [Section 2.11.3, “Changes in MySQL 5.7”](#). It is safest to perform these operations separately on the replicas and the source, and to disable replication of these operations from the source to the replica. To achieve this, use the following procedure:

1. Stop all the replicas and upgrade them. Restart them with the `--skip-slave-start` option so that they do not connect to the source. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.
2. Disable the binary log on the source. To do this without restarting the source, execute a `SET sql_log_bin = OFF` statement. Alternatively, stop the source and restart it without the `--log-bin` option. If you restart the source, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, enable the `skip_networking` system variable when you restart the source.
3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the replicas later.
4. Re-enable the binary log on the source. If you set `sql_log_bin` to `OFF` earlier, execute a `SET sql_log_bin = ON` statement. If you restarted the source to disable the binary log, restart it with `--log-bin`, and without enabling the `skip_networking` system variable so that clients and replicas can connect.
5. Restart the replicas, this time without the `--skip-slave-start` option.

If you are upgrading an existing replication setup from a version of MySQL that does not support global transaction identifiers to a version that does, you should not enable GTIDs on either the source or the replica before making sure that the setup meets all the requirements for GTID-based replication. For example `server_uuid`, which was added in MySQL 5.6, must exist for GTIDs to function correctly. See [Section 16.1.3.4, “Setting Up Replication Using GTIDs”](#), which contains information about converting existing replication setups to use GTID-based replication.

When the server is running with global transaction identifiers (GTIDs) enabled (`gtid_mode=ON`), do not enable binary logging by `mysql_upgrade`.

It is not recommended to load a dump file when GTIDs are enabled on the server (`gtid_mode=ON`), if your dump file includes system tables. `mysqldump` issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled. Also be aware that loading a dump file from a server with GTIDs enabled, into another server with GTIDs enabled, causes different transaction identifiers to be generated.

## 16.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the source has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the source server with the `--log-bin` option.
- Verify that the `server_id` system variable was set at startup on both the source and replica and that the ID value is unique on each server.
- Verify that the replica is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the replica server. For example, `--skip-slave-start` prevents the replica threads from starting until you issue a `START SLAVE` statement.
- If the replica is running, check whether it established a connection to the source. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See [Section 16.2.3, “Replication Threads”](#). If the replication I/O thread state says `Connecting to master`, check the following:
  - Verify the privileges for the user being used for replication on the source.
  - Check that the host name of the source is correct and that you are using the correct port to connect to the source. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.
  - Check the configuration file to see whether the `skip_networking` system variable has been enabled on the source or replica to disable networking. If so, comment the setting or remove it.
  - If the source has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
  - Check that you can reach the source by using `ping` or `traceroute/tracert` to reach the host.
- If the replica was running previously but has stopped, the reason usually is that some statement that succeeded on the source failed on the replica. This should never happen if you have taken a proper snapshot of the source, and never modified the data on the replica outside of the replication threads. If the replica stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in [Section 16.4.1, “Replication Features and Issues”](#). If it is a bug, see [Section 16.4.5, “How to Report Replication Bugs or Problems”](#), for instructions on how to report it.
- If a statement that succeeded on the source refuses to run on the replica, try the following procedure if it is not feasible to do a full database resynchronization by deleting the replica's databases and copying a new snapshot from the source:
  1. Determine whether the affected table on the replica is different from the table on the source. Try to understand how this happened. Then make the replica's table identical to the source's and run `START SLAVE`.
  2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the source.
  3. If you decide that the replica can skip the next statement from the source, issue the following statements:

```
mysql> SET GLOBAL sql_slave_skip_counter = N;
```

```
mysql> START SLAVE;
```

The value of `N` should be 1 if the next statement from the source does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the source.

See also [SET GLOBAL sql\\_slave\\_skip\\_counter Statement](#).

4. If you are sure that the replica started out perfectly synchronized with the source, and that no one has updated the tables involved outside of the replication threads, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

## 16.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the replica outside of the replication thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the replication SQL thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*
2. Run the replica with the `--log-slave-updates` and `--log-bin` options. These options cause the replica to log the updates that it receives from the source into its own binary logs.
3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
  - All binary log files from the source
  - All binary log files from the replica
  - The output of `SHOW MASTER STATUS` from the source at the time you discovered the problem
  - The output of `SHOW SLAVE STATUS` from the replica at the time you discovered the problem
  - Error logs from the source and the replica
4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_file` and `log_pos` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at [Section 1.6, “How to Report Bugs or Problems”](#).

This chapter explains MySQL Group Replication and how to install, configure and monitor groups. MySQL Group Replication is a MySQL Server plugin that enables you to create elastic, highly-available, fault-tolerant replication topologies.

Groups can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users, groups can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

The chapter is structured as follows:

- [Section 17.1, “Group Replication Background”](#) provides an introduction to groups and how Group Replication works.

- [Section 17.2, “Getting Started”](#) explains how to configure multiple MySQL Server instances to create a group.
- [Section 17.3, “Requirements and Limitations”](#) explains architecture and setup requirements and limitations for Group Replication.
- [Section 17.4, “Monitoring Group Replication”](#) explains how to monitor a group.
- [Section 17.5, “Group Replication Operations”](#) explains how to work with a group.
- [Section 17.6, “Group Replication Security”](#) explains how to secure a group.
- [Upgrading Group Replication](#) explains how to upgrade a group.
- [Section 17.7, “Group Replication System Variables”](#) is a reference for the system variables specific to Group Replication.
- [Section 17.8, “Frequently Asked Questions”](#) provides answers to some technical questions about deploying and operating Group Replication.
- [Section 17.9, “Group Replication Technical Details”](#) provides in-depth information about how Group Replication works.

## 17.1 Group Replication Background

This section provides background information on MySQL Group Replication.

The most common way to create a fault-tolerant system is to resort to making components redundant, in other words the component can be removed and the system should continue to operate as expected. This creates a set of challenges that raise complexity of such systems to a whole different level. Specifically, replicated databases have to deal with the fact that they require maintenance and administration of several servers instead of just one. Moreover, as servers are cooperating together to create the group several other classic distributed systems problems have to be dealt with, such as network partitioning or split brain scenarios.

Therefore, the ultimate challenge is to fuse the logic of the database and data replication with the logic of having several servers coordinated in a consistent and simple way. In other words, to have multiple servers agreeing on the state of the system and the data on each and every change that the system goes through. This can be summarized as having servers reaching agreement on each database state transition, so that they all progress as one single database or alternatively that they eventually converge to the same state. Meaning that they need to operate as a (distributed) state machine.

MySQL Group Replication provides distributed state machine replication with strong coordination between servers. Servers coordinate themselves automatically when they are part of the same group. The group can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users the group can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently. This power comes at the expense of applications having to work around the limitations imposed by such deployments.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

For a transaction to commit, the majority of the group have to agree on the order of a given transaction in the global sequence of transactions. Deciding to commit or abort a transaction is done by each server individually, but all servers make the same decision. If there is a network partition, resulting in a split where members are unable to reach agreement, then the system does not progress until this issue is resolved. Hence there is also a built-in, automatic, split-brain protection mechanism.

All of this is powered by the provided Group Communication System (GCS) protocols. These provide a failure detection mechanism, a group membership service, and safe and completely ordered message delivery. All these properties are key to creating a system which ensures that data is consistently replicated across the group of servers. At the very core of this technology lies an implementation of the Paxos algorithm. It acts as the group communication engine.

## 17.1.1 Replication Technologies

Before getting into the details of MySQL Group Replication, this section introduces some background concepts and an overview of how things work. This provides some context to help understand what is required for Group Replication and what the differences are between classic asynchronous MySQL Replication and Group Replication.

### 17.1.1.1 Primary-Secondary Replication

Traditional MySQL Replication provides a simple Primary-Secondary approach to replication. There is a primary (source) and there are one or more secondaries (replicas). The primary executes transactions, commits them and then they are later (thus asynchronously) sent to the secondaries to be either re-executed (in statement-based replication) or applied (in row-based replication). It is a shared-nothing system, where all servers have a full copy of the data by default.

**Figure 17.1 MySQL Asynchronous Replication**

There is also semisynchronous replication, which adds one synchronization step to the protocol. This means that the Primary waits, at commit time, for the secondary to acknowledge that it has received the transaction. Only then does the Primary resume the commit operation.

**Figure 17.2 MySQL Semisynchronous Replication**

In the two pictures above, you can see a diagram of the classic asynchronous MySQL Replication protocol (and its semisynchronous variant as well). The arrows between the different instances represent messages exchanged between servers or messages exchanged between servers and the client application.

### 17.1.1.2 Group Replication

Group Replication is a technique that can be used to implement fault-tolerant systems. The replication group is a set of servers that each have their own entire copy of the data (a shared-nothing replication scheme), and interact with each other through message passing. The communication layer provides a set of guarantees such as atomic message and total order message delivery. These are very powerful properties that translate into very useful abstractions that one can resort to build more advanced database replication solutions.

MySQL Group Replication builds on top of such properties and abstractions and implements a multi-source update everywhere replication protocol. A replication group is formed by multiple servers and each server in the group may execute transactions independently at any time. However, all read-write transactions commit only after they have been approved by the group. In other words, for any read-write transaction the group needs to decide whether it commits or not, so the commit operation is not a unilateral decision from the originating server. Read-only transactions need no coordination within the group and commit immediately.

When a read-write transaction is ready to commit at the originating server, the server atomically broadcasts the write values (the rows that were changed) and the corresponding write set (the unique identifiers of the rows that were updated). Because the transaction is sent through an atomic broadcast, either all servers in the group receive the transaction or none do. If they receive it, then they all receive it in the same order with respect to other transactions that were sent before. All servers therefore receive the same set of transactions in the same order, and a global total order is established for the transactions.

However, there may be conflicts between transactions that execute concurrently on different servers. Such conflicts are detected by inspecting and comparing the write sets of two different and concurrent transactions, in a process called *certification*. During certification, conflict detection is carried out at row level: if two concurrent transactions, that executed on different servers, update the same row, then there is a conflict. The conflict resolution procedure states that the transaction that was ordered first

commits on all servers, and the transaction ordered second aborts, and is therefore rolled back on the originating server and dropped by the other servers in the group. For example, if t1 and t2 execute concurrently at different sites, both changing the same row, and t2 is ordered before t1, then t2 wins the conflict and t1 is rolled back. This is in fact a distributed first commit wins rule. Note that if two transactions are bound to conflict more often than not, then it is a good practice to start them on the same server, where they have a chance to synchronize on the local lock manager instead of being rolled back as a result of certification.

For applying and externalizing the certified transactions, Group Replication permits servers to deviate from the agreed order of the transactions if this does not break consistency and validity. Group Replication is an eventual consistency system, meaning that as soon as the incoming traffic slows down or stops, all group members have the same data content. While traffic is flowing, transactions can be externalized in a slightly different order, or externalized on some members before the others. For example, in multi-primary mode, a local transaction might be externalized immediately following certification, although a remote transaction that is earlier in the global order has not yet been applied. This is permitted when the certification process has established that there is no conflict between the transactions. In single-primary mode, on the primary server, there is a small chance that concurrent, non-conflicting local transactions might be committed and externalized in a different order from the global order agreed by Group Replication. On the secondaries, which do not accept writes from clients, transactions are always committed and externalized in the agreed order.

The following figure depicts the MySQL Group Replication protocol and by comparing it to MySQL Replication (or even MySQL semisynchronous replication) you can see some differences. Note that some underlying consensus and Paxos related messages are missing from this picture for the sake of clarity.

**Figure 17.3 MySQL Group Replication Protocol**

## 17.1.2 Group Replication Use Cases

Group Replication enables you to create fault-tolerant systems with redundancy by replicating the system state to a set of servers. Even if some of the servers subsequently fail, as long it is not all or a majority, the system is still available. Depending on the number of servers which fail the group might have degraded performance or scalability, but it is still available. Server failures are isolated and independent. They are tracked by a group membership service which relies on a distributed failure detector that is able to signal when any servers leave the group, either voluntarily or due to an unexpected halt. There is a distributed recovery procedure to ensure that when servers join the group they are brought up to date automatically. There is no need for server fail-over, and the multi-source update everywhere nature ensures that even updates are not blocked in the event of a single server failure. To summarize, MySQL Group Replication guarantees that the database service is continuously available.

It is important to understand that although the database service is available, in the event of an unexpected server exit, those clients connected to it must be redirected, or failed over, to a different server. This is not something Group Replication attempts to resolve. A connector, load balancer, router, or some form of middleware are more suitable to deal with this issue. For example see [MySQL Router 8.0](#).

To summarize, MySQL Group Replication provides a highly available, highly elastic, dependable MySQL service.

### 17.1.2.1 Examples of Use Case Scenarios

The following examples are typical use cases for Group Replication.

- *Elastic Replication* - Environments that require a very fluid replication infrastructure, where the number of servers has to grow or shrink dynamically and with as few side-effects as possible. For instance, database services for the cloud.
- *Highly Available Shards* - Sharding is a popular approach to achieve write scale-out. Use MySQL Group Replication to implement highly available shards, where each shard maps to a replication group.
- *Alternative to Source-Replica replication* - In certain situations, using a single source server makes it a single point of contention. Writing to an entire group may prove more scalable under certain circumstances.
- *Autonomic Systems* - Additionally, you can deploy MySQL Group Replication purely for the automation that is built into the replication protocol (described already in this and previous chapters).

### 17.1.3 Group Replication Details

This section presents details about some of the services that Group Replication builds on.

#### 17.1.3.1 Group Membership

In MySQL Group Replication, a set of servers forms a replication group. A group has a name, which takes the form of a UUID. The group is dynamic and servers can leave (either voluntarily or involuntarily) and join it at any time. The group adjusts itself whenever servers join or leave.

If a server joins the group, it automatically brings itself up to date by fetching the missing state from an existing server. If a server leaves the group, for instance it was taken down for maintenance, the remaining servers notice that it has left and reconfigure the group automatically.

Group Replication has a group membership service that defines which servers are online and participating in the group. The list of online servers is referred to as a *view*. Every server in the group has a consistent view of which servers are the members participating actively in the group at a given moment in time.

Group members must agree not only on transaction commits, but also on which is the current view. If existing members agree that a new server should become part of the group, the group is reconfigured to integrate that server in it, which triggers a view change. If a server leaves the group, either voluntarily or not, the group dynamically rearranges its configuration and a view change is triggered.

In the case where a member leaves the group voluntarily, it first initiates a dynamic group reconfiguration, during which all members have to agree on a new view without the leaving server. However, if a member leaves the group involuntarily, for example because it has stopped unexpectedly or the network connection is down, it cannot initiate the reconfiguration. In this situation, Group Replication's failure detection mechanism recognizes after a short period of time that the member has left, and a reconfiguration of the group without the failed member is proposed. As with a member

that leaves voluntarily, the reconfiguration requires agreement from the majority of servers in the group. However, if the group is not able to reach agreement, for example because it partitioned in such a way that there is no majority of servers online, the system is not able to dynamically change the configuration, and blocks to prevent a split-brain situation. This situation requires intervention from an administrator.

It is possible for a member to go offline for a short time, then attempt to rejoin the group again before the failure detection mechanism has detected its failure, and before the group has been reconfigured to remove the member. In this situation, the rejoicing member forgets its previous state, but if other members send it messages that are intended for its pre-crash state, this can cause issues including possible data inconsistency. If a member in this situation participates in XCom's consensus protocol, it could potentially cause XCom to deliver different values for the same consensus round, by making a different decision before and after failure.

To counter this possibility, from MySQL 5.7.22, servers are given a unique identifier when they join a group. This enables Group Replication to be aware of the situation where a new incarnation of the same server (with the same address but a new identifier) is trying to join the group while its old incarnation is still listed as a member. The new incarnation is blocked from joining the group until the old incarnation can be removed by a reconfiguration. If Group Replication is stopped and restarted on the server, the member becomes a new incarnation and cannot rejoin until the suspicion times out.

### 17.1.3.2 Failure Detection

Group Replication includes a failure detection mechanism that is able to find and report which servers are silent and as such assumed to be dead. At a high level, the failure detector is a distributed service that provides information about which servers may be dead (suspicions). Suspicions are triggered when servers go mute. When server A does not receive messages from server B during a given period, a timeout occurs and a suspicion is raised. Later if the group agrees that the suspicions are probably true, then the group decides that a given server has indeed failed. This means that the remaining members in the group take a coordinated decision to exclude a given member.

Suspicions are triggered when servers go mute. When server A does not receive messages from server B during a given period, a timeout occurs and a suspicion is raised.

If a server gets isolated from the rest of the group, then it suspects that all others have failed. Being unable to secure agreement with the group (as it cannot secure a quorum), its suspicion does not have consequences. When a server is isolated from the group in this way, it is unable to execute any local transactions.

### 17.1.3.3 Fault-tolerance

MySQL Group Replication builds on an implementation of the Paxos distributed algorithm to provide distributed coordination between servers. As such, it requires a majority of servers to be active to reach quorum and thus make a decision. This has direct impact on the number of failures the system can tolerate without compromising itself and its overall functionality. The number of servers ( $n$ ) needed to tolerate  $f$  failures is then  $n = 2 \times f + 1$ .

In practice this means that to tolerate one failure the group must have three servers in it. As such if one server fails, there are still two servers to form a majority (two out of three) and allow the system to continue to make decisions automatically and progress. However, if a second server fails *involuntarily*, then the group (with one server left) blocks, because there is no majority to reach a decision.

The following is a small table illustrating the formula above.

| Capacity  |
|-----------|
| 3         |
| Failures  |
| 2         |
| Tolerated |
| 1         |

| Majority<br>States | Tolerated |
|--------------------|-----------|
| 2                  | 1         |
| 3                  | 2         |
| 4                  | 3         |
| 5                  | 3         |
| 6                  | 2         |
| 7                  | 2         |

The next Chapter covers technical aspects of Group Replication.

## 17.2 Getting Started

MySQL Group Replication is provided as a plugin to MySQL server, and each server in a group requires configuration and installation of the plugin. This section provides a detailed tutorial with the steps required to create a replication group with at least three members.

### Tip

An alternative way to deploy multiple instances of MySQL is by using InnoDB Cluster, which uses Group Replication and wraps it in a programmatic environment that enables you to easily work with groups of MySQL server instances in the [MySQL Shell 8.0](#). In addition, InnoDB Cluster interfaces seamlessly with MySQL Router and simplifies deploying MySQL with high availability. See [Using MySQL AdminAPI](#).

### 17.2.1 Deploying Group Replication in Single-Primary Mode

Each of the MySQL server instances in a group can run on an independent physical host machine, which is the recommended way to deploy Group Replication. This section explains how to create a replication group with three MySQL Server instances, each running on a different host machine. See [Section 17.2.2, “Deploying Group Replication Locally”](#) for information about deploying multiple MySQL server instances running Group Replication on the same host machine, for example for testing purposes.

**Figure 17.4 Group Architecture**

This tutorial explains how to get and deploy MySQL Server with the Group Replication plugin, how to configure each server instance before creating a group, and how to use Performance Schema monitoring to verify that everything is working correctly.

### 17.2.1.1 Deploying Instances for Group Replication

The first step is to deploy at least three instances of MySQL Server, this procedure demonstrates using multiple hosts for the instances, named s1, s2 and s3. It is assumed that MySQL Server was installed on each of the hosts, see [Chapter 2, “Installing and Upgrading MySQL”](#). Group Replication is a built-in MySQL plugin provided with MySQL Server 5.7.17 and later. For more background information on MySQL plugins, see [Section 5.5, “MySQL Server Plugins”](#).

In this example, three instances are used for the group, which is the minimum number of instances to create a group. Adding more instances increases the fault tolerance of the group. For example if the group consists of three members, in event of failure of one instance the group can continue. But in the event of another failure the group can no longer continue processing write transactions. By adding more instances, the number of servers which can fail while the group continues to process transactions also increases. The maximum number of instances which can be used in a group is nine. For more information see [Section 17.1.3.2, “Failure Detection”](#).

### 17.2.1.2 Configuring an Instance for Group Replication

This section explains the configuration settings required for MySQL Server instances that you want to use for Group Replication. For background information, see [Section 17.3, “Requirements and Limitations”](#).

- [Storage Engines](#)
- [Replication Framework](#)
- [Group Replication Settings](#)

## Storage Engines

For Group Replication, data must be stored in the InnoDB transactional storage engine (for details of why, see [Section 17.3.1, “Group Replication Requirements”](#)). The use of other storage engines, including the temporary `MEMORY` storage engine, might cause errors in Group Replication. Set the `disabled_storage_engines` system variable as follows to prevent their use:

```
disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"
```

Note that with the `MyISAM` storage engine disabled, when you are upgrading a MySQL instance to a release where `mysql_upgrade` is still used (before MySQL 8.0.16), `mysql_upgrade` might fail with an error. To handle this, you can re-enable that storage engine while you run `mysql_upgrade`, then disable it again when you restart the server. For more information, see [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

## Replication Framework

The following settings configure replication according to the MySQL Group Replication requirements.

```
server_id=1
gtid_mode=ON
enforce_gtid_consistency=ON
master_info_repository=TABLE
relay_log_info_repository=TABLE
binlog_checksum=None
log_slave_updates=ON
log_bin=binlog
binlog_format=ROW
```

These settings configure the server to use the unique identifier number 1, to enable global transaction identifiers and to store replication metadata in system tables instead of files. Additionally, it instructs the server to turn on binary logging, use row-based format and disable binary log event checksums. For more details see [Section 17.3.1, “Group Replication Requirements”](#).

## Group Replication Settings

At this point the option file ensures that the server is configured and is instructed to instantiate the replication infrastructure under a given configuration. The following section configures the Group Replication settings for the server.

```
plugin_load_add='group_replication.so'
transaction_write_set_extraction=XXHASH64
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaa-aaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "s1:33061"
group_replication_group_seeds= "s1:33061,s2:33061,s3:33061"
group_replication_bootstrap_group=off
```

- `plugin-load-add` adds the Group Replication plugin to the list of plugins which the server loads at startup. This is preferable in a production deployment to installing the plugin manually.
- Configuring `group_replication_group_name` tells the plugin that the group that it is joining, or creating, is named "aaaaaaaa-aaaa-aaaa-aaa-aaaaaaaaaaaa".

The value of `group_replication_group_name` must be a valid UUID. This UUID is used internally when setting GTIDs for Group Replication events in the binary log. You can use `SELECT UUID()` to generate a UUID.

- Configuring the `group_replication_start_on_boot` variable to `off` instructs the plugin to not start operations automatically when the server starts. This is important when setting up Group Replication as it ensures you can configure the server before manually starting the plugin. Once the member is configured you can set `group_replication_start_on_boot` to `on` so that Group Replication starts automatically upon server boot.
- Configuring `group_replication_local_address` sets the network address and port which the member uses for internal communication with other members in the group. Group Replication uses this address for internal member-to-member connections involving remote instances of the group communication engine (XCom, a Paxos variant).

#### Important

This address must be different to the `hostname` and `port` used for SQL and it must not be used for client applications. It must be only be used for internal communication between the members of the group while running Group Replication.

The network address configured by `group_replication_local_address` must be resolvable by all group members. For example, if each server instance is on a different machine with a fixed network address, you could use the IP address of the machine, such as 10.0.0.1. If you use a host name, you must use a fully qualified name, and ensure it is resolvable through DNS, correctly configured `/etc/hosts` files, or other name resolution processes. From MySQL 8.0.14, IPv6 addresses (or host names that resolve to them) can be used as well as IPv4 addresses. A group can contain a mix of members using IPv6 and members using IPv4. For more information on Group Replication support for IPv6 networks and on mixed IPv4 and IPv6 groups, see [Support For IPv6 And For Mixed IPv6 And IPv4 Groups](#).

The recommended port for `group_replication_local_address` is 33061. `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. You can use the same port for all members of a replication group as long as the host names or IP addresses are all different, as demonstrated in this tutorial. Alternatively you can use the same host name or IP address for all members as long as the ports are all different, for example as shown in [Section 17.2.2, “Deploying Group Replication Locally”](#).

- Configuring `group_replication_group_seeds` sets the hostname and port of the group members which are used by the new member to establish its connection to the group. These members are called the seed members. Once the connection is established, the group membership information is listed at `performance_schema.replication_group_members`. Usually the `group_replication_group_seeds` list contains the `hostname:port` of each of the group member's `group_replication_local_address`, but this is not obligatory and a subset of the group members can be chosen as seeds.

#### Important

The `hostname:port` listed in `group_replication_group_seeds` is the seed member's internal network address, configured by `group_replication_local_address` and not the SQL `hostname:port` used for client connections, and shown for example in `performance_schema.replication_group_members` table.

The server that starts the group does not make use of this option, since it is the initial server and as such, it is in charge of bootstrapping the group. In other words, any existing data which is on the server bootstrapping the group is what is used as the data for the next joining member. The second

server joining asks the one and only member in the group to join, any missing data on the second server is replicated from the donor data on the bootstrapping member, and then the group expands. The third server joining can ask any of these two to join, data is synchronized to the new member, and then the group expands again. Subsequent servers repeat this procedure when joining.

### Warning

When joining multiple servers at the same time, make sure that they point to seed members that are already in the group. Do not use members that are also joining the group as seeds, because they might not yet be in the group when contacted.

It is good practice to start the bootstrap member first, and let it create the group. Then make it the seed member for the rest of the members that are joining. This ensures that there is a group formed when joining the rest of the members.

Creating a group and joining multiple members at the same time is not supported. It might work, but chances are that the operations race and then the act of joining the group ends up in an error or a time out.

- Configuring `group_replication_bootstrap_group` instructs the plugin whether to bootstrap the group or not. In this case, even though s1 is the first member of the group we set this variable to off in the option file. Instead we configure `group_replication_bootstrap_group` when the instance is running, to ensure that only one member actually bootstraps the group.

### Important

The `group_replication_bootstrap_group` variable must only be enabled on one server instance belonging to a group at any time, usually the first time you bootstrap the group (or in case the entire group is brought down and back up again). If you bootstrap the group multiple times, for example when multiple server instances have this option set, then they could create an artificial split brain scenario, in which two distinct groups with the same name exist. Always set `group_replication_bootstrap_group=off` after the first server instance comes online.

Configuration for all servers in the group is quite similar. You need to change the specifics about each server (for example `server_id`, `datadir`, `group_replication_local_address`). This is illustrated later in this tutorial.

### 17.2.1.3 User Credentials

Group Replication uses the asynchronous replication protocol to achieve [Section 17.9.5, “Distributed Recovery”](#), synchronizing group members before joining them to the group. The distributed recovery process relies on a replication channel named `group_replication_recovery` which is used to transfer transactions from donor members to members that join the group. Therefore you need to set up a replication user with the correct permissions so that Group Replication can establish direct member-to-member recovery replication channels.

Start the MySQL server instance and then connect a client to it. Create a MySQL user with the `REPLICATION SLAVE` privilege. This process can be captured in the binary log and then you can rely on distributed recovery to replicate the statements used to create the user. Alternatively, you can disable binary logging using `SET SQL_LOG_BIN=0;` and then create the user manually on each member, for example if you want to avoid the changes being propagated to other server instances. If you do decide to disable binary logging, ensure you reenable it once you have configured the user.

In the following example the user `rpl_user` with the password `password` is shown. When configuring your servers use a suitable user name and password.

```
mysql> CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
```

```
mysql> GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
mysql> FLUSH PRIVILEGES;
```

If binary logging was disabled, enable it again once the user has been created using `SET SQL_LOG_BIN=1`.

Once the user has been configured, use the `CHANGE MASTER TO` statement to configure the server to use the given credentials for the `group_replication_recovery` replication channel the next time it needs to recover its state from another member. Issue the following, replacing `rpl_user` and `password` with the values used when creating the user.

```
mysql> CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' \\
FOR CHANNEL 'group_replication_recovery';
```

Distributed recovery is the first step taken by a server that joins the group and does not have the same set of transactions as the group members. If these credentials are not set correctly for the `group_replication_recovery` replication channel and the `rpl_user` as shown, the server cannot connect to the donor members and run the distributed recovery process to gain synchrony with the other group members, and hence ultimately cannot join the group. See [Section 17.9.5, “Distributed Recovery”](#).

Similarly, if the server cannot correctly identify the other members via the server's `hostname` the recovery process can fail. It is recommended that operating systems running MySQL have a properly configured unique `hostname`, either using DNS or local settings. This `hostname` can be verified in the `Member_host` column of the `performance_schema.replication_group_members` table. If multiple group members externalize a default `hostname` set by the operating system, there is a chance of the member not resolving to the correct member address and not being able to join the group. In such a situation use `report_host` to configure a unique `hostname` to be externalized by each of the servers.

#### 17.2.1.4 Launching Group Replication

Once server s1 has been configured and started, install the Group Replication plugin. If you used `plugin_load_add='group_replication.so'` in the option file then the Group Replication plugin is installed and you can proceed to the next step. In the event that you decide to install the plugin manually, connect to the server and issue the following:

```
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

#### Important

The `mysql.session` user must exist before you can load Group Replication. `mysql.session` was added in MySQL version 5.7.19. If your data dictionary was initialized using an earlier version you must perform the MySQL upgrade procedure (see [Section 2.11, “Upgrading MySQL”](#)). If the upgrade is not run, Group Replication fails to start with the error message `There was an error when trying to access the server with user: mysql.session@localhost. Make sure the user is present in the server and that mysql_upgrade was ran after a server update..`

To check that the plugin was installed successfully, issue `SHOW PLUGINS;` and check the output. It should show something like this:

```
mysql> SHOW PLUGINS;
+-----+-----+-----+-----+
| Name | Status | Type | Library | License |
+-----+-----+-----+-----+
| binlog | ACTIVE | STORAGE ENGINE | NULL | PROPRIETARY |
| (...) | | | | |

```

|                   |        |                   |                      |             |
|-------------------|--------|-------------------|----------------------|-------------|
| group_replication | ACTIVE | GROUP REPLICATION | group_replication.so | PROPRIETARY |
|-------------------|--------|-------------------|----------------------|-------------|

### 17.2.1.5 Bootstrapping the Group

The process of starting a group for the first time is called bootstrapping. You use the `group_replication_bootstrap_group` system variable to bootstrap a group. The bootstrap should only be done by a single server, the one that starts the group and only once. This is why the value of the `group_replication_bootstrap_group` option was not stored in the instance's option file. If it is saved in the option file, upon restart the server automatically bootstraps a second group with the same name. This would result in two distinct groups with the same name. The same reasoning applies to stopping and restarting the plugin with this option set to `ON`. Therefore to safely bootstrap the group, connect to `s1` and issue:

```
mysql> SET GLOBAL group_replication_bootstrap_group=ON;
mysql> START GROUP_REPLICATION;
mysql> SET GLOBAL group_replication_bootstrap_group=OFF;
```

Once the `START GROUP_REPLICATION` statement returns, the group has been started. You can check that the group is now created and that there is one member in it:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STATUS |
|---------------------------|--------------------------------------|-------------|-------------|---------------|
| group_replication_applier | ce9be252-2b71-11e6-b8f4-00212844f856 | s1          | 3306        | ONLINE        |

The information in this table confirms that there is a member in the group with the unique identifier `ce9be252-2b71-11e6-b8f4-00212844f856`, that it is `ONLINE` and is at `s1` listening for client connections on port `3306`.

For the purpose of demonstrating that the server is indeed in a group and that it is able to handle load, create a table and add some content to it.

```
mysql> CREATE DATABASE test;
mysql> USE test;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 TEXT NOT NULL);
mysql> INSERT INTO t1 VALUES (1, 'Luis');
```

Check the content of table `t1` and the binary log.

```
mysql> SELECT * FROM t1;
+---+---+
| c1 | c2 |
+---+---+
| 1 | Luis |
+---+---+

mysql> SHOW BINLOG EVENTS;
+-----+-----+-----+-----+-----+-----+
| Log_name | Pos | Event_type | Server_id | End_log_pos | Info
+-----+-----+-----+-----+-----+
| binlog.000001 | 4 | Format_desc | 1 | 123 | Server ver: 5.7.34-log, Binlog ver: 4
| binlog.000001 | 123 | Previous_gtids | 1 | 150 |
| binlog.000001 | 150 | Gtid | 1 | 211 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa-aaaa
| binlog.000001 | 211 | Query | 1 | 270 | BEGIN
| binlog.000001 | 270 | View_change | 1 | 369 | view_id=14724817264259180:1
| binlog.000001 | 369 | Query | 1 | 434 | COMMIT
| binlog.000001 | 434 | Gtid | 1 | 495 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa-aaaa
| binlog.000001 | 495 | Query | 1 | 585 | CREATE DATABASE test
| binlog.000001 | 585 | Gtid | 1 | 646 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa-aaaa
| binlog.000001 | 646 | Query | 1 | 770 | use `test`; CREATE TABLE t1 (c1 INT PRIN
| binlog.000001 | 770 | Gtid | 1 | 831 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa-aaaa
| binlog.000001 | 831 | Query | 1 | 899 | BEGIN
| binlog.000001 | 899 | Table_map | 1 | 942 | table_id: 108 (test.t1)
| binlog.000001 | 942 | Write_rows | 1 | 984 | table_id: 108 flags: STMT_END_F
| binlog.000001 | 984 | Xid | 1 | 1011 | COMMIT /* xid=38 */
```

```
+-----+-----+-----+-----+
```

As seen above, the database and the table objects were created and their corresponding DDL statements were written to the binary log. Also, the data was inserted into the table and written to the binary log. The importance of the binary log entries is illustrated in the following section when the group grows and distributed recovery is executed as new members try to catch up and become online.

### 17.2.1.6 Adding Instances to the Group

At this point, the group has one member in it, server s1, which has some data in it. It is now time to expand the group by adding the other two servers configured previously.

#### Adding a Second Instance

In order to add a second instance, server s2, first create the configuration file for it. The configuration is similar to the one used for server s1, except for things such as the `server_id`. These different lines are highlighted in the listing below.

```
[mysqld]

#
Disable other storage engines
#
disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"

#
Replication configuration parameters
#
server_id=2
gtid_mode=ON
enforce_gtid_consistency=ON
master_info_repository=TABLE
relay_log_info_repository=TABLE
binlog_checksum=NONE
log_slave_updates=ON
log_bin=binlog
binlog_format=ROW

#
Group Replication configuration
#
transaction_write_set_extraction=XXHASH64
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address="s2:33061"
group_replication_group_seeds="s1:33061,s2:33061,s3:33061"
group_replication_bootstrap_group= off
```

Similar to the procedure for server s1, with the option file in place you launch the server. Then configure the recovery credentials as follows. The commands are the same as used when setting up server s1 as the user is shared within the group. This member needs to have the same replication user configured in [Section 17.2.1.3, “User Credentials”](#). If you are relying on distributed recovery to configure the user on all members, when s2 connects to the seed s1 the replication user is replicated to s1. If you did not have binary logging enabled when you configured the user credentials on s1, you must create the replication user on s2. In this case, connect to s2 and issue:

```
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
SET SQL_LOG_BIN=1;
CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' \\
FOR CHANNEL 'group_replication_recovery';
```

If necessary, install the Group Replication plugin, see [Section 17.2.1.4, “Launching Group Replication”](#).

Start Group Replication and s2 starts the process of joining the group.

```
mysql> START GROUP_REPLICATION;
```

Unlike the previous steps that were the same as those executed on s1, here there is a difference in that you do *not* need to bootstrap the group because the group already exists. In other words on s2 `group_replication_bootstrap_group` is set to off, and you do not issue `SET GLOBAL group_replication_bootstrap_group=ON`; before starting Group Replication, because the group has already been created and bootstrapped by server s1. At this point server s2 only needs to be added to the already existing group.

### Tip

When Group Replication starts successfully and the server joins the group it checks the `super_read_only` variable. By setting `super_read_only` to ON in the member's configuration file, you can ensure that servers which fail when starting Group Replication for any reason do not accept transactions. If the server should join the group as read-write instance, for example as the primary in a single-primary group or as a member of a multi-primary group, when the `super_read_only` variable is set to ON then it is set to OFF upon joining the group.

Checking the `performance_schema.replication_group_members` table again shows that there are now two `ONLINE` servers in the group.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+-----+-----+-----+-----+-----+
| CHANNEL_NAME | MEMBER_ID | MEMBER_HOST | MEMBER_PORT | MEMBER_STATE |
+-----+-----+-----+-----+
| group_replication_applier | 395409e1-6dfa-11e6-970b-00212844f856 | s1 | 3306 | ONLINE
| group_replication_applier | ac39f1e6-6dfa-11e6-a69d-00212844f856 | s2 | 3306 | ONLINE
+-----+-----+-----+-----+
```

When s2 attempted to join the group, [Section 17.9.5, “Distributed Recovery”](#) ensured that s2 applied the same transactions which s1 had applied. Once this process completed, s2 could join the group as a member, and at this point it is marked as `ONLINE`. In other words it must have already caught up with server s1 automatically. Once s2 is `ONLINE`, it then begins to process transactions with the group. Verify that s2 has indeed synchronized with server s1 as follows.

```
mysql> SHOW DATABASES LIKE 'test';
+-----+
| Database (test) |
+-----+
| test |
+-----+

mysql> SELECT * FROM test.t1;
+---+---+
| c1 | c2 |
+---+---+
| 1 | Luis |
+---+---+

mysql> SHOW BINLOG EVENTS;
+-----+-----+-----+-----+-----+-----+
| Log_name | Pos | Event_type | Server_id | End_log_pos | Info |
+-----+-----+-----+-----+-----+
| binlog.000001 | 4 | Format_desc | 2 | 123 | Server ver: 5.7.34-log, Binlog ver: 4 |
| binlog.000001 | 123 | Previous_gtids | 2 | 150 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa-aaaaaa-aaaaaa-aaaaaa-aaaaaa' |
| binlog.000001 | 150 | Gtid | 1 | 211 | BEGIN |
| binlog.000001 | 211 | Query | 1 | 270 | CREATE DATABASE test |
| binlog.000001 | 270 | View_change | 1 | 369 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa-aaaaaa-aaaaaa-aaaaaa-aaaaaa' |
| binlog.000001 | 369 | Query | 1 | 434 | COMMIT |
| binlog.000001 | 434 | Gtid | 1 | 495 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa-aaaaaa-aaaaaa-aaaaaa-aaaaaa' |
| binlog.000001 | 495 | Query | 1 | 585 | BEGIN |
| binlog.000001 | 585 | Gtid | 1 | 646 | CREATE TABLE t1 (c1 INT PRIMARY KEY) ENGINE=InnoDB |
| binlog.000001 | 646 | Query | 1 | 770 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa-aaaaaa-aaaaaa-aaaaaa-aaaaaa' |
| binlog.000001 | 770 | Gtid | 1 | 831 | BEGIN |
| binlog.000001 | 831 | Query | 1 | 890 | CREATE TABLE t1 (c1 INT PRIMARY KEY) ENGINE=InnoDB |
| binlog.000001 | 890 | Table_map | 1 | 933 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa-aaaaaa-aaaaaa-aaaaaa-aaaaaa' |
| binlog.000001 | 933 | Write_rows | 1 | 975 | COMMIT /* xid=30 */ |
| binlog.000001 | 975 | Xid | 1 | 1002 | */
```

```

| binlog.000001 | 1002 | Gtid | 1 | 1063 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaaaa'
| binlog.000001 | 1063 | Query | 1 | 1122 | BEGIN
| binlog.000001 | 1122 | View_change | 1 | 1261 | view_id=14724832985483517:2
| binlog.000001 | 1261 | Query | 1 | 1326 | COMMIT
+-----+-----+-----+-----+-----+-----+

```

As seen above, the second server has been added to the group and it has replicated the changes from server s1 automatically using distributed recovery. In other words, the transactions applied on s1 up to the point in time that s2 joined the group have been replicated to s2.

## Adding Additional Instances

Adding additional instances to the group is essentially the same sequence of steps as adding the second server, except that the configuration has to be changed as it had to be for server s2. To summarise the required commands:

### 1. Create the configuration file

```

[mysqld]

#
Disable other storage engines
#
disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"

#
Replication configuration parameters
#
server_id=3
gtid_mode=ON
enforce_gtid_consistency=ON
master_info_repository=TABLE
relay_log_info_repository=TABLE
binlog_checksum=NONE
log_slave_updates=ON
log_bin=binlog
binlog_format=ROW

#
Group Replication configuration
#
group_replication_group_name="aaaaaaaa-aaaa-aaa-aaa-aaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "s3:33061"
group_replication_group_seeds= "s1:33061,s2:33061,s3:33061"
group_replication_bootstrap_group= off

```

### 2. Start the server and connect to it. Configure the recovery credentials for the group\_replication\_recovery channel.

```

SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
FLUSH PRIVILEGES;
SET SQL_LOG_BIN=1;
CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' \\
FOR CHANNEL 'group_replication_recovery';

```

### 4. Install the Group Replication plugin and start it.

```

INSTALL PLUGIN group_replication SONAME 'group_replication.so';
START GROUP_REPLICATION;

```

At this point server s3 is booted and running, has joined the group and caught up with the other servers in the group. Consulting the `performance_schema.replication_group_members` table again confirms this is the case.

```

mysql> SELECT * FROM performance_schema.replication_group_members;
+-----+-----+-----+-----+-----+
| CHANNEL_NAME | MEMBER_ID | MEMBER_HOST | MEMBER_PORT | MEMBER_IP |
+-----+-----+-----+-----+-----+

```

| group_replication_applier | 395409e1-6dfa-11e6-970b-00212844f856 | s1 |  | 3306 | ONLINE |  |
|---------------------------|--------------------------------------|----|--|------|--------|--|
| group_replication_applier | 7eb217ff-6df3-11e6-966c-00212844f856 | s3 |  | 3306 | ONLINE |  |
| group_replication_applier | ac39f1e6-6dfa-11e6-a69d-00212844f856 | s2 |  | 3306 | ONLINE |  |

Issuing this same query on server s2 or server s1 yields the same result. Also, you can verify that server s3 has caught up:

```
mysql> SHOW DATABASES LIKE 'test';
+-----+
| Database (test) |
+-----+
| test |
+-----+

mysql> SELECT * FROM test.t1;
+---+---+
| c1 | c2 |
+---+---+
| 1 | Luis |
+---+---+

mysql> SHOW BINLOG EVENTS;
+-----+-----+-----+-----+-----+-----+
| Log_name | Pos | Event_type | Server_id | End_log_pos | Info
+-----+-----+-----+-----+-----+-----+
| binlog.000001 | 4 | Format_desc | 3 | 123 | Server ver: 5.7.34-log, Binlog ver: 4
| binlog.000001 | 123 | Previous_gtids | 3 | 150 |
| binlog.000001 | 150 | Gtid | 1 | 211 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa
| binlog.000001 | 211 | Query | 1 | 270 | BEGIN
| binlog.000001 | 270 | View_change | 1 | 369 | view_id=14724832985483517:1
| binlog.000001 | 369 | Query | 1 | 434 | COMMIT
| binlog.000001 | 434 | Gtid | 1 | 495 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa
| binlog.000001 | 495 | Query | 1 | 585 | CREATE DATABASE test
| binlog.000001 | 585 | Gtid | 1 | 646 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa
| binlog.000001 | 646 | Query | 1 | 770 | use `test`; CREATE TABLE t1 (c1 INT PRI
| binlog.000001 | 770 | Gtid | 1 | 831 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa
| binlog.000001 | 831 | Query | 1 | 890 | BEGIN
| binlog.000001 | 890 | Table_map | 1 | 933 | table_id: 108 (test.t1)
| binlog.000001 | 933 | Write_rows | 1 | 975 | table_id: 108 flags: STMT_END_F
| binlog.000001 | 975 | Xid | 1 | 1002 | COMMIT /* xid=29 */
| binlog.000001 | 1002 | Gtid | 1 | 1063 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa
| binlog.000001 | 1063 | Query | 1 | 1122 | BEGIN
| binlog.000001 | 1122 | View_change | 1 | 1261 | view_id=14724832985483517:2
| binlog.000001 | 1261 | Query | 1 | 1326 | COMMIT
| binlog.000001 | 1326 | Gtid | 1 | 1387 | SET @@SESSION.GTID_NEXT= 'aaaaaaaaaaaa
| binlog.000001 | 1387 | Query | 1 | 1446 | BEGIN
| binlog.000001 | 1446 | View_change | 1 | 1585 | view_id=14724832985483517:3
| binlog.000001 | 1585 | Query | 1 | 1650 | COMMIT
+-----+-----+-----+-----+-----+-----+
```

## 17.2.2 Deploying Group Replication Locally

The most common way to deploy Group Replication is using multiple server instances, to provide high availability. It is also possible to deploy Group Replication locally, for example for testing purposes. This section explains how you can deploy Group Replication locally.

### Important

Group Replication is usually deployed on multiple hosts because this ensures that high-availability is provided. The instructions in this section are not suitable for production deployments because all MySQL server instances are running on the same single host. In the event of failure of this host, the whole group fails. Therefore this information should be used for testing purposes and it should not be used in a production environments.

This section explains how to create a replication group with three MySQL Server instances on one physical machine. This means that three data directories are needed, one per server instance, and

that you need to configure each instance independently. This - procedure assumes that MySQL Server was downloaded and unpacked - into the directory named `mysql-5.7`. Each MySQL server instance requires a specific data directory. Create a directory named `data`, then in that directory create a subdirectory for each server instance, for example `s1`, `s2` and `s3`, and initialize each one.

```
mysql-5.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-5.7 --datadir=$PWD/data/s1
mysql-5.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-5.7 --datadir=$PWD/data/s2
mysql-5.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-5.7 --datadir=$PWD/data/s3
```

Inside `data/s1`, `data/s2`, `data/s3` is an initialized data directory, containing the mysql system database and related tables and much more. To learn more about the initialization procedure, see [Section 2.10.1, “Initializing the Data Directory”](#).

### Warning

Do not use `-initialize-insecure` in production environments, it is only used here to simplify the tutorial. For more information on security settings, see [Section 17.6, “Group Replication Security”](#).

## Configuration of Local Group Replication Members

When you are following [Section 17.2.1.2, “Configuring an Instance for Group Replication”](#), you need to add configuration for the data directories added in the previous section. For example:

```
[mysqld]
server configuration
datadir=<full_path_to_data>/data/s1
basedir=<full_path_to_bin>/mysql-8.0/
port=24801
socket=<full_path_to_sock_dir>/s1.sock
```

These settings configure MySQL server to use the data directory created earlier and which port the server should open and start listening for incoming connections.

### Note

The non-default port of 24801 is used because in this tutorial the three server instances use the same hostname. In a setup with three different machines this would not be required.

Group Replication requires a network connection between the members, which means that each member must be able to resolve the network address of all of the other members. For example in this tutorial all three instances run on one machine, so to ensure that the members can contact each other you could add a line to the option file such as `report_host=127.0.0.1`.

Then each member needs to be able to connect to the other members on their `group_replication_local_address`. For example in the option file of member `s1` add:

```
group_replication_local_address= "127.0.0.1:24901"
group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
```

This configures `s1` to use port 24901 for internal group communication with seed members. For each server instance you want to add to the group, make these changes in the option file of the member. For each member you must ensure a unique address is specified, so use a unique port per instance for `group_replication_local_address`. Usually you want all members to be able to serve as seeds for members that are joining the group and have not got the transactions processed by the group. In this case, add all of the ports to `group_replication_group_seeds` as shown above.

The remaining steps of [Section 17.2.1, “Deploying Group Replication in Single-Primary Mode”](#) apply equally to a group which you have deployed locally in this way.

## 17.3 Requirements and Limitations

This section lists and explains the requirements and limitations of Group Replication.

### 17.3.1 Group Replication Requirements

Server instances that you want to use for Group Replication must satisfy the following requirements.

#### Infrastructure

- **InnoDB Storage Engine.** Data must be stored in the `InnoDB` transactional storage engine. Transactions are executed optimistically and then, at commit time, are checked for conflicts. If there are conflicts, in order to maintain consistency across the group, some transactions are rolled back. This means that a transactional storage engine is required. Moreover, `InnoDB` provides some additional functionality that enables better management and handling of conflicts when operating together with Group Replication. The use of other storage engines, including the temporary `MEMORY` storage engine, might cause errors in Group Replication. You can prevent the use of other storage engines by setting the `disabled_storage_engines` system variable on group members, for example:

```
disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"
```

- **Primary Keys.** Every table that is to be replicated by the group must have a defined primary key, or primary key equivalent where the equivalent is a non-null unique key. Such keys are required as a unique identifier for every row within a table, enabling the system to determine which transactions conflict by identifying exactly which rows each transaction has modified.
- **IPv4 Network.** The group communication engine used by MySQL Group Replication only supports IPv4. Therefore, Group Replication requires an IPv4 network infrastructure.
- **Network Performance.** MySQL Group Replication is designed to be deployed in a cluster environment where server instances are very close to each other. The performance and stability of a group can be impacted by both network latency and network bandwidth. Bi-directional communication must be maintained at all times between all group members. If either inbound or outbound communication is blocked for a server instance (for example, by a firewall, or by connectivity issues), the member cannot function in the group, and the group members (including the member with issues) might not be able to report the correct member status for the affected server instance.

#### Server Instance Configuration

The following options must be configured on server instances that are members of a group.

- **Unique Server Identifier.** Use the `server_id` system variable to configure the server with a unique server ID, as required for all servers in replication topologies. With the default server ID of 0, servers in a replication topology cannot connect to each other. The server ID must be a positive integer between 1 and  $(2^{32})-1$ , and it must be different from every other server ID in use by any other server in the replication topology.
- **Binary Log Active.** Set `--log-bin[=log_file_name]`. MySQL Group Replication replicates binary log contents, therefore the binary log needs to be on for it to operate. This option is enabled by default. See [Section 5.4.4, “The Binary Log”](#).
- **Replica Updates Logged.** Set `--log-slave-updates`. Servers need to log binary logs that are applied through the replication applier. Servers in the group need to log all transactions that they receive and apply from the group. This is required because recovery is conducted by relying on binary logs from participants in the group. Therefore, copies of each transaction need to exist on every server, even for those transactions that were not initiated on the server itself.
- **Binary Log Row Format.** Set `--binlog-format=row`. Group Replication relies on row-based replication format to propagate changes consistently among the servers in the group. It relies on row-based infrastructure to be able to extract the necessary information to detect conflicts among transactions that execute concurrently in different servers in the group. See [Section 16.2.1, “Replication Formats”](#).

- **Binary Log Checksums Off.** Set `--binlog-checksum=NONE`. Due to a design limitation of replication event checksums, Group Replication cannot make use of them, and they must be disabled.
- **Global Transaction Identifiers On.** Set `gtid_mode=ON` and `enforce_gtid_consistency=ON`. Group Replication uses global transaction identifiers to track exactly which transactions have been committed on every server instance and thus be able to infer which servers have executed transactions that could conflict with already committed transactions elsewhere. In other words, explicit transaction identifiers are a fundamental part of the framework to be able to determine which transactions may conflict. See [Section 16.1.3, “Replication with Global Transaction Identifiers”](#).
- **Replication Information Repositories.** Set `master_info_repository=TABLE` and `relay_log_info_repository=TABLE`. The replication applier needs to have the source and replica metadata written to the `mysql.slave_master_info` and `mysql.slave_relay_log_info` system tables. This ensures the Group Replication plugin has consistent recoverability and transactional management of the replication metadata. See [Section 16.2.4.2, “Replication Metadata Repositories”](#).
- **Transaction Write Set Extraction.** Set `--transaction-write-set-extraction=XXHASH64` so that while collecting rows to log them to the binary log, the server collects the write set as well. The write set is based on the primary keys of each row and is a simplified and compact view of a tag that uniquely identifies the row that was changed. This tag is then used for detecting conflicts.
- **Lower Case Table Names.** Set `--lower-case-table-names` to the same value on all group members. A setting of 1 is correct for the use of the `InnoDB` storage engine, which is required for Group Replication. Note that this setting is not the default on all platforms.
- **Multithreaded Appliers.** Group Replication members can be configured as multithreaded replicas, enabling transactions to be applied in parallel. A nonzero value for `slave_parallel_workers` enables the multithreaded applier on the member, and up to 1024 parallel applier threads can be specified. If you do this, the following settings are also required:

`slave_preserve_commit_order` This setting is required to ensure that the final commit of parallel transactions is in the same order as the original transactions. Group Replication relies on consistency mechanisms built around the guarantee that all participating members receive and apply committed transactions in the same order.

`slave_parallel_type=LOGICAL` This setting is required with `slave_preserve_commit_order=1`. It specifies the policy used to decide which transactions are allowed to execute in parallel on the replica.

Setting `slave_parallel_workers=0` disables parallel execution and gives the replica a single applier thread and no coordinator thread. With that setting, the `slave_parallel_type` and `slave_preserve_commit_order` options have no effect and are ignored.

### 17.3.2 Group Replication Limitations

The following known limitations exist for Group Replication. Note that the limitations and issues described for multi-primary mode groups can also apply in single-primary mode clusters during a failover event, while the newly elected primary flushes out its applier queue from the old primary.

#### Tip

Group Replication is built on GTID based replication, therefore you should also be aware of [Section 16.1.3.6, “Restrictions on Replication with GTIDs”](#).

- **Gap Locks.** Group Replication's certification process for concurrent transactions does not take into account [gap locks](#), as information about gap locks is not available outside of [InnoDB](#). See [Gap Locks](#) for more information.

**Note**

For a group in multi-primary mode, unless you rely on [REPEATABLE READ](#) semantics in your applications, we recommend using the [READ COMMITTED](#) isolation level with Group Replication. InnoDB does not use gap locks in [READ COMMITTED](#), which aligns the local conflict detection within InnoDB with the distributed conflict detection performed by Group Replication. For a group in single-primary mode, only the primary accepts writes, so the [READ COMMITTED](#) isolation level is not important to Group Replication.

- **Table Locks and Named Locks.** The certification process does not take into account table locks (see [Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Statements”](#)) or named locks (see [GET\\_LOCK\(\)](#)).
- **Replication Event Checksums.** Due to a design limitation of replication event checksums, Group Replication cannot currently make use of them. Therefore set `--binlog-checksum=NONE`.
- **SERIALIZABLE Isolation Level.** [SERIALIZABLE](#) isolation level is not supported in multi-primary groups by default. Setting a transaction isolation level to [SERIALIZABLE](#) configures Group Replication to refuse to commit the transaction.
- **Concurrent DDL versus DML Operations.** Concurrent data definition statements and data manipulation statements executing against the same object but on different servers is not supported when using multi-primary mode. During execution of Data Definition Language (DDL) statements on an object, executing concurrent Data Manipulation Language (DML) on the same object but on a different server instance has the risk of conflicting DDL executing on different instances not being detected.
- **Foreign Keys with Cascading Constraints.** Multi-primary mode groups (members all configured with `group_replication_single_primary_mode=OFF`) do not support tables with multi-level foreign key dependencies, specifically tables that have defined [CASCADING foreign key constraints](#). This is because foreign key constraints that result in cascading operations executed by a multi-primary mode group can result in undetected conflicts and lead to inconsistent data across the members of the group. Therefore we recommend setting `group_replication_enforce_update_everywhere_checks=ON` on server instances used in multi-primary mode groups to avoid undetected conflicts.

In single-primary mode this is not a problem as it does not allow concurrent writes to multiple members of the group and thus there is no risk of undetected conflicts.

- **MySQL Enterprise Audit and MySQL Enterprise Firewall.** Prior to version 5.7.21 MySQL Enterprise Audit and MySQL Enterprise Firewall use [MyISAM](#) tables in the [mysql](#) system database. Group Replication does not support [MyISAM](#) tables.
- **Multi-primary Mode Deadlock.** When a group is operating in multi-primary mode, [SELECT ... FOR UPDATE](#) statements can result in a deadlock. This is because the lock is not shared across the members of the group, therefore the expectation for such a statement might not be reached.
- **Replication Filters.** Replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state.

## Limit on Group Size

The maximum number of MySQL servers that can be members of a single replication group is 9. If further members attempt to join the group, their request is refused. This limit has been identified from

testing and benchmarking as a safe boundary where the group performs reliably on a stable local area network.

## Limits on Transaction Size

If an individual transaction results in message contents which are large enough that the message cannot be copied between group members over the network within a 5-second window, members can be suspected of having failed, and then expelled, just because they are busy processing the transaction. Large transactions can also cause the system to slow due to problems with memory allocation. To avoid these issues use the following mitigations:

- Where possible, try and limit the size of your transactions. For example, split up files used with `LOAD DATA` into smaller chunks.
- Use the system variable `group_replication_transaction_size_limit` to specify the maximum transaction size that the group accepts. In MySQL 5.7, this system variable defaults to zero, but in MySQL 8.0, it defaults to a maximum transaction size of 150000000 bytes (approximately 143 MB). Transactions above this limit are rolled back and are not sent to Group Replication's Group Communication System (GCS) for distribution to the group. Adjust the value of this variable depending on the maximum message size that you need the group to tolerate, bearing in mind that the time taken to process a transaction is proportional to its size.
- Use the system variable `group_replication_compression_threshold` to specify a message size above which compression is applied. This system variable defaults to 1000000 bytes (1 MB), so large messages are automatically compressed. Compression is carried out by Group Replication's Group Communication System (GCS) when it receives a message that was permitted by the `group_replication_transaction_size_limit` setting but exceeds the `group_replication_compression_threshold` setting. If you set the system variable value to zero, compression is deactivated. For more information, see [Section 17.9.7.2, “Message Compression”](#).

If you have deactivated message compression and do not specify a maximum transaction size, the upper size limit for a message that can be handled by the applier thread on a member of a replication group is the value of the member's `slave_max_allowed_packet` system variable, which has a default and maximum value of 1073741824 bytes (1 GB). A message that exceeds this limit fails when the receiving member attempts to handle it. The upper size limit for a message that a group member can originate and attempt to transmit to the group is 4294967295 bytes (approximately 4 GB). This is a hard limit on the packet size that is accepted by the group communication engine for Group Replication (XCom, a Paxos variant), which receives messages after GCS has handled them. A message that exceeds this limit fails when the originating member attempts to broadcast it.

## 17.4 Monitoring Group Replication

Use the Performance Schema tables to monitor Group Replication, assuming that the [Performance Schema](#) is enabled. Group Replication adds the following tables:

- `performance_schema.replication_group_member_stats`
- `performance_schema.replication_group_members`

These Performance Schema replication tables also show information about Group Replication:

- `performance_schema.replication_connection_status` shows information regarding Group Replication, for example the transactions that have been received from the group and queued in the applier queue (the relay log).
- `performance_schema.replication_applier_status` shows the state of the Group Replication related channels and threads. If there are many different worker threads applying transactions, then the worker tables can also be used to monitor what each worker thread is doing.

The replication channels created by the Group Replication plugin are named:

- `group_replication_recovery` - This channel is used for the replication changes that are related to the distributed recovery phase.
- `group_replication_applier` - This channel is used for the incoming changes from the group. This is the channel used to apply transactions coming directly from the group.

The following sections describe how to interpret the information available.

### 17.4.1 Group Replication Server States

There are various states that a server instance can be in. If servers are communicating properly, all report the same states for all servers. However, if there is a network partition, or a server leaves the group, then different information could be reported, depending on which server is queried. If the server has left the group then it cannot report updated information about the other servers' states. If there is a partition, such that quorum is lost, servers are not able to coordinate between themselves. As a consequence, they cannot guess what the status of different servers is. Therefore, instead of guessing their state they report that some servers are unreachable.

**Table 17.1 Server State**

| Field                    | Description                                                                                                                                                                                          | Group Synchronized |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| <code>ONLINE</code>      | The member is ready to serve as a fully functional group member, meaning that the client can connect and start executing transactions.                                                               | Yes                |
| <code>RECOVERING</code>  | The member is in the process of becoming an active member of the group and is currently going through the recovery process, receiving state information from a donor.                                | No                 |
| <code>OFFLINE</code>     | The plugin is loaded but the member does not belong to any group.                                                                                                                                    | No                 |
| <code>ERROR</code>       | The state of the member. Whenever there is an error on the recovery phase or while applying changes, the server enters this state.                                                                   | No                 |
| <code>UNREACHABLE</code> | Whenever the local failure detector suspects that a given server is not reachable, because for example it was disconnected involuntarily, it shows that server's state as <code>UNREACHABLE</code> . | No                 |

#### Important

Once an instance enters `ERROR` state, the `super_read_only` option is set to `ON`. To leave the `ERROR` state you must manually configure the instance with `super_read_only=OFF`.

Note that Group Replication is *not* synchronous, but eventually synchronous. More precisely, transactions are delivered to all group members in the same order, but their execution is not synchronized, meaning that after a transaction is accepted to be committed, each member commits at its own pace.

### 17.4.2 The `replication_group_members` Table

The `performance_schema.replication_group_members` table is used for monitoring the status of the different server instances that are members of the group. The information in the table is updated whenever there is a view change, for example when the configuration of the group is dynamically

changed when a new member joins. At that point, servers exchange some of their metadata to synchronize themselves and continue to cooperate together. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member. This table can be used to get a high level view of the state of a replication group, for example by issuing:

| SELECT * FROM performance_schema.replication_group_members; |                                      |             |             |              |             |
|-------------------------------------------------------------|--------------------------------------|-------------|-------------|--------------|-------------|
| CHANNEL_NAME                                                | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STATE | MEMBER_ROLE |
| group_replication_applier                                   | 041f26d8-f3f3-11e8-adff-080027337932 | example1    | 3306        | ONLINE       | SECONDARY   |
| group_replication_applier                                   | f60a3e10-f3f2-11e8-8258-080027337932 | example2    | 3306        | ONLINE       | SECONDARY   |
| group_replication_applier                                   | fc890014-f3f2-11e8-a9fd-080027337932 | example3    | 3306        | ONLINE       | PRIMARY     |

Based on this result we can see that the group consists of three members, each member's host and port number which clients use to connect to the member, and the `server_uuid` of the member. The `MEMBER_STATE` column shows one of the [Section 17.4.1, “Group Replication Server States”](#), in this case it shows that all three members in this group are `ONLINE`, and the `MEMBER_ROLE` column shows that there are two secondaries, and a single primary. Therefore this group must be running in single-primary mode. The `MEMBER_VERSION` column can be useful when you are upgrading a group and are combining members running different MySQL versions. See [Section 17.4.1, “Group Replication Server States”](#) for more information.

For more information about the `Member_host` value and its impact on the distributed recovery process, see [Section 17.2.1.3, “User Credentials”](#).

### 17.4.3 The replication\_group\_member\_stats Table

Each member in a replication group certifies and applies transactions received by the group. Statistics regarding the certifier and applier procedures are useful to understand how the applier queue is growing, how many conflicts have been found, how many transactions were checked, which transactions are committed everywhere, and so on.

The `performance_schema.replication_group_member_stats` table provides group-level information related to the certification process, and also statistics for the transactions received and originated by each individual member of the replication group. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member. Note that refreshing of statistics for remote members is controlled by the message period specified in the `group_replication_flow_control_period` option, so these can differ slightly from the locally collected statistics for the member where the query is made. To use this table to monitor a Group Replication member, issue:

```
mysql> SELECT * FROM performance_schema.replication_group_member_stats\G
```

These fields are important for monitoring the performance of the members connected in the group. For example, suppose that one of the group's members always reports a large number of transactions in its queue compared to other members. This means that the member is delayed and is not able to keep up to date with the other members of the group. Based on this information, you could decide to either remove the member from the group, or delay the processing of transactions on the other members of the group in order to reduce the number of queued transactions. This information can also help you to decide how to adjust the flow control of the Group Replication plugin, see [Section 17.9.7.3, “Flow Control”](#).

## 17.5 Group Replication Operations

This section describes the different modes of deploying Group Replication, explains common operations for managing groups and provides information about how to tune your groups. .

### 17.5.1 Deploying in Multi-Primary or Single-Primary Mode

Group Replication operates in the following different modes:

- single-primary mode
- multi-primary mode

The default mode is single-primary. It is not possible to have members of the group deployed in different modes, for example one configured in multi-primary mode while another one is in single-primary mode. To switch between modes, the group and not the server, needs to be restarted with a different operating configuration. Regardless of the deployed mode, Group Replication does not handle client-side fail-over, that must be handled by the application itself, a connector or a middleware framework such as a proxy or [MySQL Router 8.0](#).

When deployed in multi-primary mode, statements are checked to ensure they are compatible with the mode. The following checks are made when Group Replication is deployed in multi-primary mode:

- If a transaction is executed under the SERIALIZABLE isolation level, then its commit fails when synchronizing itself with the group.
- If a transaction executes against a table that has foreign keys with cascading constraints, then the transaction fails to commit when synchronizing itself with the group.

These checks can be deactivated by setting the option

`group_replication_enforce_update_everywhere_checks` to `FALSE`. When deploying in single-primary mode, this option *must* be set to `FALSE`.

### 17.5.1.1 Single-Primary Mode

In this mode the group has a single-primary server that is set to read-write mode. All the other members in the group are set to read-only mode (with `super-read-only=ON`). This happens automatically. The primary is typically the first server to bootstrap the group, all other servers that join automatically learn about the primary server and are set to read only.

**Figure 17.5 New Primary Election**

When in single-primary mode, some of the checks deployed in multi-primary mode are disabled, because the system enforces that only a single server writes to the group. For example, changes to tables that have cascading foreign keys are allowed, whereas in multi-primary mode they are not. Upon primary member failure, an automatic primary election mechanism chooses the new primary member. The election process is performed by looking at the new view, and ordering the potential new primaries based on the value of `group_replication_member_weight`. Assuming the group is

operating with all members running the same MySQL version, then the member with the highest value for `group_replication_member_weight` is elected as the new primary. In the event that multiple servers have the same `group_replication_member_weight`, the servers are then prioritized based on their `server_uuid` in lexicographical order and by picking the first one. Once a new primary is elected, it is automatically set to read-write and the other secondaries remain as secondaries, and as such, read-only.

When a new primary is elected, it is only writable once it has processed all of the transactions that came from the old primary. This avoids possible concurrency issues between old transactions from the old primary and the new ones being executed on this member. It is a good practice to wait for the new primary to apply its replication related relay-log before re-routing client applications to it.

If the group is operating with members that are running different versions of MySQL then the election process can be impacted. For example, if any member does not support `group_replication_member_weight`, then the primary is chosen based on `server_uuid` order from the members of the lower major version. Alternatively, if all members running different MySQL versions do support `group_replication_member_weight`, the primary is chosen based on `group_replication_member_weight` from the members of the lower major version.

### 17.5.1.2 Multi-Primary Mode

In multi-primary mode, there is no notion of a single primary. There is no need to engage an election procedure because there is no server playing any special role.

**Figure 17.6 Client Failover**

All servers are set to read-write mode when joining the group.

### 17.5.1.3 Finding the Primary

The following example shows how to find out which server is currently the primary when deployed in single-primary mode.

```
mysql> SHOW STATUS LIKE 'group_replication_primary_member';
```

## 17.5.2 Tuning Recovery

Whenever a new member joins a replication group, it connects to a suitable donor and fetches the data that it has missed up until the point it is declared online. This critical component in Group Replication is fault tolerant and configurable. The following section explains how recovery works and how to tune the settings

## Donor Selection

A random donor is selected from the existing online members in the group. This way there is a good chance that the same server is not selected more than once when multiple members enter the group.

If the connection to the selected donor fails, a new connection is automatically attempted to a new candidate donor. Once the connection retry limit is reached the recovery procedure terminates with an error.

### Note

A donor is picked randomly from the list of online members in the current view.

## Enhanced Automatic Donor Switchover

The other main point of concern in recovery as a whole is to make sure that it copes with failures. Hence, Group Replication provides robust error detection mechanisms. In earlier versions of Group Replication, when reaching out to a donor, recovery could only detect connection errors due to authentication issues or some other problem. The reaction to such problematic scenarios was to switch over to a new donor thus a new connection attempt was made to a different member.

This behavior was extended to also cover other failure scenarios:

- *Purged data scenarios* - If the selected donor contains some purged data that is needed for the recovery process then an error occurs. Recovery detects this error and a new donor is selected.
- *Duplicated data* - If a server joining the group already contains some data that conflicts with the data coming from the selected donor during recovery then an error occurs. This could be caused by some errant transactions present in the server joining the group.

One could argue that recovery should fail instead of switching over to another donor, but in heterogeneous groups there is chance that other members share the conflicting transactions and others do not. For that reason, upon error, recovery selects another donor from the group.

- *Other errors* - If any of the recovery threads fail (receiver or applier threads fail) then an error occurs and recovery switches over to a new donor.

### Note

In case of some persistent failures or even transient failures recovery automatically retries connecting to the same or a new donor.

## Donor Connection Retries

The recovery data transfer relies on the binary log and existing MySQL replication framework, therefore it is possible that some transient errors could cause errors in the receiver or applier threads. In such cases, the donor switch over process has retry functionality, similar to that found in regular replication.

## Number of Attempts

The number of attempts a server joining the group makes when trying to connect to a donor from the pool of donors is 10. This is configured through the `group_replication_recovery_retry_count` plugin variable . The following command sets the maximum number of attempts to connect to a donor to 10.

```
mysql> SET GLOBAL group_replication_recovery_retry_count= 10;
```

Note that this accounts for the global number of attempts that the server joining the group makes connecting to each one of the suitable donors.

## Sleep Routines

The `group_replication_recovery_reconnect_interval` plugin variable defines how much time the recovery process should sleep between donor connection attempts. This variable has its default set to 60 seconds and you can change this value dynamically. The following command sets the recovery donor connection retry interval to 120 seconds.

```
mysql> SET GLOBAL group_replication_recovery_reconnect_interval= 120;
```

Note, however, that recovery does not sleep after every donor connection attempt. As the server joining the group is connecting to different servers and not to the same one over and over again, it can assume that the problem that affects server A does not affect server B. As such, recovery suspends only when it has gone through all the possible donors. Once the server joining the group has tried to connect to all the suitable donors in the group and none remains, the recovery process sleeps for the number of seconds configured by the `group_replication_recovery_reconnect_interval` variable.

### 17.5.3 Network Partitioning

The group needs to achieve consensus whenever a change that needs to be replicated happens. This is the case for regular transactions but is also required for group membership changes and some internal messaging that keeps the group consistent. Consensus requires a majority of group members to agree on a given decision. When a majority of group members is lost, the group is unable to progress and blocks because it cannot secure majority or quorum.

Quorum may be lost when there are multiple involuntary failures, causing a majority of servers to be removed abruptly from the group. For example in a group of 5 servers, if 3 of them become silent at once, the majority is compromised and thus no quorum can be achieved. In fact, the remaining two are not able to tell if the other 3 servers have crashed or whether a network partition has isolated these 2 alone and therefore the group cannot be reconfigured automatically.

On the other hand, if servers exit the group voluntarily, they instruct the group that it should reconfigure itself. In practice, this means that a server that is leaving tells others that it is going away. This means that other members can reconfigure the group properly, the consistency of the membership is maintained and the majority is recalculated. For example, in the above scenario of 5 servers where 3 leave at once, if the 3 leaving servers warn the group that they are leaving, one by one, then the membership is able to adjust itself from 5 to 2, and at the same time, securing quorum while that happens.

#### Note

Loss of quorum is by itself a side-effect of bad planning. Plan the group size for the number of expected failures (regardless whether they are consecutive, happen all at once or are sporadic).

The following sections explain what to do if the system partitions in such a way that no quorum is automatically achieved by the servers in the group.

#### Tip

A primary that has been excluded from a group after a majority loss followed by a reconfiguration can contain extra transactions that are not included in the new group. If this happens, the attempt to add back the excluded member from the group results in an error with the message `This member has more executed transactions than those present in the group.`

## Detecting Partitions

The `replication_group_members` performance schema table presents the status of each server in the current view from the perspective of this server. The majority of the time the system does not

run into partitioning, and therefore the table shows information that is consistent across all servers in the group. In other words, the status of each server on this table is agreed by all in the current view. However, if there is network partitioning, and quorum is lost, then the table shows the status **UNREACHABLE** for those servers that it cannot contact. This information is exported by the local failure detector built into Group Replication.

**Figure 17.7 Losing Quorum**

To understand this type of network partition the following section describes a scenario where there are initially 5 servers working together correctly, and the changes that then happen to the group once only 2 servers are online. The scenario is depicted in the figure.

As such, lets assume that there is a group with these 5 servers in it:

- Server s1 with member identifier `199b2df7-4aaaf-11e6-bb16-28b2bd168d07`
- Server s2 with member identifier `199bb88e-4aaaf-11e6-babe-28b2bd168d07`
- Server s3 with member identifier `1999b9fb-4aaaf-11e6-bb54-28b2bd168d07`

- Server s4 with member identifier `19ab72fc-4AAF-11e6-bb51-28b2bd168d07`
- Server s5 with member identifier `19b33846-4AAF-11e6-ba81-28b2bd168d07`

Initially the group is running fine and the servers are happily communicating with each other. You can verify this by logging into s1 and looking at its `replication_group_members` performance schema table. For example:

```
mysql> SELECT MEMBER_ID, MEMBER_STATE, MEMBER_ROLE FROM performance_schema.replication_group_members;
+-----+-----+-----+
| MEMBER_ID | MEMBER_STATE | MEMBER_ROLE |
+-----+-----+-----+
| 1999b9fb-4AAF-11e6-bb54-28b2bd168d07 | ONLINE | SECONDARY |
| 199b2df7-4AAF-11e6-bb16-28b2bd168d07 | ONLINE | PRIMARY |
| 199bb88e-4AAF-11e6-babe-28b2bd168d07 | ONLINE | SECONDARY |
| 19ab72fc-4AAF-11e6-bb51-28b2bd168d07 | ONLINE | SECONDARY |
| 19b33846-4AAF-11e6-ba81-28b2bd168d07 | ONLINE | SECONDARY |
+-----+-----+-----+
```

However, moments later there is a catastrophic failure and servers s3, s4 and s5 stop unexpectedly. A few seconds after this, looking again at the `replication_group_members` table on s1 shows that it is still online, but several others members are not. In fact, as seen below they are marked as `UNREACHABLE`. Moreover, the system could not reconfigure itself to change the membership, because the majority has been lost.

```
mysql> SELECT MEMBER_ID, MEMBER_STATE FROM performance_schema.replication_group_members;
+-----+-----+
| MEMBER_ID | MEMBER_STATE |
+-----+-----+
| 1999b9fb-4AAF-11e6-bb54-28b2bd168d07 | UNREACHABLE |
| 199b2df7-4AAF-11e6-bb16-28b2bd168d07 | ONLINE |
| 199bb88e-4AAF-11e6-babe-28b2bd168d07 | ONLINE |
| 19ab72fc-4AAF-11e6-bb51-28b2bd168d07 | UNREACHABLE |
| 19b33846-4AAF-11e6-ba81-28b2bd168d07 | UNREACHABLE |
+-----+-----+
```

The table shows that s1 is now in a group that has no means of progressing without external intervention, because a majority of the servers are unreachable. In this particular case, the group membership list needs to be reset to allow the system to proceed, which is explained in this section. Alternatively, you could also choose to stop Group Replication on s1 and s2 (or stop completely s1 and s2), figure out what happened with s3, s4 and s5 and then restart Group Replication (or the servers).

## Unblocking a Partition

Group replication enables you to reset the group membership list by forcing a specific configuration. For instance in the case above, where s1 and s2 are the only servers online, you could choose to force a membership configuration consisting of only s1 and s2. This requires checking some information about s1 and s2 and then using the `group_replication_force_members` variable.

**Figure 17.8 Forcing a New Membership**

Suppose that you are back in the situation where s1 and s2 are the only servers left in the group. Servers s3, s4 and s5 have left the group unexpectedly. To make servers s1 and s2 continue, you want to force a membership configuration that contains only s1 and s2.

#### Warning

This procedure uses `group_replication_force_members` and should be considered a last resort remedy. It *must* be used with extreme care and only for overriding loss of quorum. If misused, it could create an artificial split-brain scenario or block the entire system altogether.

Recall that the system is blocked and the current configuration is the following (as perceived by the local failure detector on s1):

```
mysql> SELECT MEMBER_ID, MEMBER_STATE FROM performance_schema.replication_group_members;
+-----+-----+
| MEMBER_ID | MEMBER_STATE |
+-----+-----+
| 1999b9fb-4aaaf-11e6-bb54-28b2bd168d07 | UNREACHABLE |
+-----+-----+
```

|                                                    |
|----------------------------------------------------|
| 199b2df7-4aaf-11e6-bb16-28b2bd168d07   ONLINE      |
| 199bb88e-4aaf-11e6-babe-28b2bd168d07   ONLINE      |
| 19ab7fc-4aaf-11e6-bb51-28b2bd168d07   UNREACHABLE  |
| 19b33846-4aaf-11e6-ba81-28b2bd168d07   UNREACHABLE |

The first thing to do is to check what is the local address (group communication identifier) for s1 and s2. Log in to s1 and s2 and get that information as follows.

```
mysql> SELECT @@group_replication_local_address;
```

Once you know the group communication addresses of s1 (`127.0.0.1:10000`) and s2 (`127.0.0.1:10001`), you can use that on one of the two servers to inject a new membership configuration, thus overriding the existing one that has lost quorum. To do that on s1:

```
mysql> SET GLOBAL group_replication_force_members="127.0.0.1:10000,127.0.0.1:10001";
```

This unblocks the group by forcing a different configuration. Check `replication_group_members` on both s1 and s2 to verify the group membership after this change. First on s1.

```
mysql> SELECT MEMBER_ID, MEMBER_STATE FROM performance_schema.replication_group_members;
+-----+-----+
| MEMBER_ID | MEMBER_STATE |
+-----+-----+
| b5ffe505-4ab6-11e6-b04b-28b2bd168d07 | ONLINE
| b60907e7-4ab6-11e6-afb7-28b2bd168d07 | ONLINE
+-----+-----+
```

And then on s2.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+-----+-----+
| MEMBER_ID | MEMBER_STATE |
+-----+-----+
| b5ffe505-4ab6-11e6-b04b-28b2bd168d07 | ONLINE
| b60907e7-4ab6-11e6-afb7-28b2bd168d07 | ONLINE
+-----+-----+
```

When forcing a new membership configuration, make sure that any servers are going to be forced out of the group are indeed stopped. In the scenario depicted above, if s3, s4 and s5 are not really unreachable but instead are online, they may have formed their own functional partition (they are 3 out of 5, hence they have the majority). In that case, forcing a group membership list with s1 and s2 could create an artificial split-brain situation. Therefore it is important before forcing a new membership configuration to ensure that the servers to be excluded are indeed shutdown and if they are not, shut them down before proceeding.

After you have used the `group_replication_force_members` system variable to successfully force a new group membership and unblock the group, ensure that you clear the system variable. `group_replication_force_members` must be empty in order to issue a `START GROUP_REPLICATION` statement.

## 17.5.4 Using MySQL Enterprise Backup with Group Replication

[MySQL Enterprise Backup](#) is a commercially-licensed backup utility for MySQL Server, available with [MySQL Enterprise Edition](#). This section explains how to back up and subsequently restore a Group Replication member using MySQL Enterprise Backup. The same technique can be used to quickly add a new member to a group.

### Backing up a Group Replication Member Using MySQL Enterprise Backup

Backing up a Group Replication member is similar to backing up a stand-alone MySQL instance. The following instructions assume that you are already familiar with how to use MySQL Enterprise Backup to perform a backup; if that is not the case, please review the [MySQL Enterprise Backup 4.1 User's Guide](#), especially [Backing Up a Database Server](#). Also note the requirements described in

Grant MySQL Privileges to Backup Administrator and [Using MySQL Enterprise Backup with Group Replication](#).

Consider the following group with three members, `s1`, `s2`, and `s3`, running on hosts with the same names:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s1 | 3306 | ONLINE
| s2 | 3306 | ONLINE
| s3 | 3306 | ONLINE
+-----+-----+-----+
```

Using MySQL Enterprise Backup, create a backup of `s2` by issuing on its host, for example, the following command:

```
s2> mysqlbackup --defaults-file=/etc/my.cnf --backup-image=/backups/my.mbi_`date +%d%m_%H%M` \
 --backup-dir=/backups/backup_`date +%d%m_%H%M` --user=root -p \
 --host=127.0.0.1 backup-to-image
```

#### Note

- When backing up a secondary member, as MySQL Enterprise Backup cannot write backup status and metadata to a read-only server instance, it might issue warnings similar to the following one during the backup operation:

```
181113 21:31:08 MAIN WARNING: This backup operation cannot write to backup
progress. The MySQL server is running with the --super-read-only option.
```

You can avoid the warning by using the `--no-history-logging` option with your backup command.

## Restoring a Failed Member

Assume one of the members (`s3` in the following example) is irreconcilably corrupted. The most recent backup of group member `s2` can be used to restore `s3`. Here are the steps for performing the restore:

1. *Copy the backup of s2 onto the host for s3.* The exact way to copy the backup depends on the operating system and tools available to you. In this example, we assume the hosts are both Linux servers and use SCP to copy the files between them:

```
s2/backups> scp my.mbi_2206_1429 s3:/backups
```

2. *Restore the backup.* Connect to the target host (the host for `s3` in this case), and restore the backup using MySQL Enterprise Backup. Here are the steps:

- a. Stop the corrupted server, if it is still running. For example, on Linux distributions that use systemd:

```
s3> systemctl stop mysqld
```

- b. Preserve the configuration file `auto.cnf`, located in the corrupted server's data directory, by copying it to a safe location outside of the data directory. This is for preserving the `server's UUID`, which is needed later.

- c. Delete all contents in the data directory of `s3`. For example:

```
s3> rm -rf /var/lib/mysql/*
```

If the system variables `innodb_data_home_dir`, `innodb_log_group_home_dir`, and `innodb_undo_directory` point to any directories other than the data directory, they should also be made empty; otherwise, the restore operation fails.

- d. Restore backup of `s2` onto the host for `s3`:

```
s3> mysqlbackup --defaults-file=/etc/my.cnf \
 --datadir=/var/lib/mysql \
 --backup-image=/backups/my.mbi_2206_1429 \
 --backup-dir=/tmp/restore_`date +%d%m_%H%M` copy-back-and-apply-log
```

#### Note

The command above assumes that the binary logs and relay logs on `s2` and `s3` have the same base name and are at the same location on the two servers. If these conditions are not met, for MySQL Enterprise Backup 4.1.2 and later, you should use the `--log-bin` and `--relay-log` options to restore the binary log and relay log to their original file paths on `s3`. For example, if you know that on `s3` the binary log's base name is `s3-bin` and the relay-log's base name is `s3-relay-bin`, your restore command should look like:

```
mysqlbackup --defaults-file=/etc/my.cnf \
 --datadir=/var/lib/mysql \
 --backup-image=/backups/my.mbi_2206_1429 \
 --log-bin=s3-bin --relay-log=s3-relay-bin \
 --backup-dir=/tmp/restore_`date +%d%m_%H%M` copy-back-and-apply-log
```

Being able to restore the binary log and relay log to the right file paths makes the restore process easier; if that is impossible for some reason, see [Rebuild the Failed Member to Rejoin as a New Member](#).

3. *Restore the `auto.cnf` file for `s3`.* To rejoin the replication group, the restored member *must* have the same `server_uuid` it used to join the group before. Supply the old server UUID by copying the `auto.cnf` file preserved in step 2 above into the data directory of the restored member.

#### Note

If you cannot supply the failed member's original `server_uuid` to the restored member by restoring its old `auto.cnf` file, you must let the restored member join the group as a new member; see instructions in [Rebuild the Failed Member to Rejoin as a New Member](#) below on how to do that.

4. *Start the restored server.* For example, on Linux distributions that use `systemd`:

```
systemctl start mysqld
```

#### Note

If the server you are restoring is a primary member, perform the steps described in [Restoring a Primary Member](#) before starting the restored server.

5. *Restart Group Replication.* Connect to the restarted `s3` using, for example, a `mysql` client, and issue the following command:

```
mysql> START GROUP_REPLICATION;
```

Before the restored instance can become an online member of the group, it needs to apply any transactions that have happened to the group after the backup was taken; this is achieved using Group Replication's [distributed recovery](#) mechanism, and the process starts after the `START GROUP_REPLICATION` statement has been issued. To check the member status of the restored instance, issue:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_member_stats;
```

| member_host | member_port | member_state |
|-------------|-------------|--------------|
| s1          | 3306        | ONLINE       |
| s2          | 3306        | ONLINE       |
| s3          | 3306        | RECOVERING   |

This shows that `s3` is applying transactions to catch up with the group. Once it has caught up with the rest of the group, its `member_state` changes to `ONLINE`:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s1 | 3306 | ONLINE |
| s2 | 3306 | ONLINE |
| s3 | 3306 | ONLINE |
+-----+-----+-----+
```

### Note

If the server you are restoring is a primary member, once it has gained synchrony with the group and become `ONLINE`, perform the steps described at the end of [Restoring a Primary Member](#) to revert the configuration changes you had made to the server before you started it.

The member has now been fully restored from the backup and functions as a regular member of the group.

## Rebuild the Failed Member to Rejoin as a New Member

Sometimes, the steps outlined above in [Restoring a Failed Member](#) cannot be carried out because, for example, the binary log or relay log is corrupted, or it is just missing from the backup. In such a situation, use the backup to rebuild the member, and then add it to the group as a new member. In the steps below, we assume the rebuilt member is named `s3`, like the failed member, and it is run on the same host as `s3` was:

1. *Copy the backup of `s2` onto the host for `s3`.* The exact way to copy the backup depends on the operating system and tools available to you. In this example we assume the hosts are both Linux servers and use SCP to copy the files between them:

```
s2/backups> scp my.mbi_2206_1429 s3:/backups
```

2. *Restore the backup.* Connect to the target host (the host for `s3` in this case), and restore the backup using MySQL Enterprise Backup. Here are the steps:

- a. Stop the corrupted server, if it is still running. For example, on Linux distributions that use systemd:

```
s3> systemctl stop mysqld
```

- b. Delete all contents in the data directory of `s3`. For example:

```
s3> rm -rf /var/lib/mysql/*
```

If the system variables `innodb_data_home_dir`, `innodb_log_group_home_dir`, and `innodb_undo_directory` point to any directories other than the data directory, they should also be made empty; otherwise, the restore operation fails.

- c. Restore the backup of `s2` onto the host of `s3`. With this approach, we are rebuilding `s3` as a new member, for which we do not need or do not want to use the old binary and relay logs in the backup; therefore, if these logs have been included in your backup, exclude them using the `--skip-binlog` and `--skip-relaylog` options:

```
s3> mysqlbackup --defaults-file=/etc/my.cnf \
```

```
--datadir=/var/lib/mysql \
--backup-image=/backups/my.mbi_2206_1429 \
--backup-dir=/tmp/restore_`date +%d%m_%H%M` \
--skip-binlog --skip-relaylog \
copy-back-and-apply-log
```

**Notes**

- If you have healthy binary log and relay logs in the backup that you can transfer onto the target host with no issues, you are recommended to follow the easier procedure as described in [Restoring a Failed Member](#) above.
- Do NOT restore manually the corrupted server's `auto.cnf` file to the data directory of the new member—when the rebuilt `s3` joins the group as a new member, it is going to be assigned a new server UUID.

3. *Start the restored server.* For example, on Linux distributions that use `systemd`:

```
systemctl start mysqld
```

**Note**

If the server you are restoring is a primary member, perform the steps described in [Restoring a Primary Member before starting the restored server](#).

4. *Reconfigure the restored member to join Group Replication.* Connect to the restored server with a `mysql` client and reset the source and replica information with the following commands:

```
mysql> RESET MASTER;
```

```
mysql> RESET SLAVE ALL;
```

For the restored server to be able to recover automatically using Group Replication's built-in mechanism for [distributed recovery](#), configure the server's `gtid_executed` variable. To do this, use the `backup_gtid_executed.sql` file included in the backup of `s2`, which is usually restored under the restored member's data directory. Disable binary logging, use the `backup_gtid_executed.sql` file to configure `gtid_executed`, and then re-enable binary logging by issuing the following statements with your `mysql` client:

```
mysql> SET SQL_LOG_BIN=OFF;
mysql> SOURCE datadir/backup_gtid_executed.sql
mysql> SET SQL_LOG_BIN=ON;
```

Then, configure the [Group Replication user credentials](#) on the member:

```
mysql> CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' /
FOR CHANNEL 'group_replication_recovery';
```

5. *Restart Group Replication.* Issue the following command to the restored server with your `mysql` client:

```
mysql> START GROUP_REPLICATION;
```

Before the restored instance can become an online member of the group, it needs to apply any transactions that have happened to the group after the backup was taken; this is achieved using Group Replication's [distributed recovery](#) mechanism, and the process starts after the [START GROUP\\_REPLICATION](#) statement has been issued. To check the member status of the restored instance, issue:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_member_stats;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
```

|    |      |            |
|----|------|------------|
| s3 | 3306 | RECOVERING |
| s2 | 3306 | ONLINE     |
| s1 | 3306 | ONLINE     |

This shows that `s3` is applying transactions to catch up with the group. Once it has caught up with the rest of the group, its `member_state` changes to `ONLINE`:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s3 | 3306 | ONLINE |
| s2 | 3306 | ONLINE |
| s1 | 3306 | ONLINE |
+-----+-----+-----+
```

### Note

If the server you are restoring is a primary member, once it has gained synchrony with the group and become `ONLINE`, perform the steps described at the end of [Restoring a Primary Member](#) to revert the configuration changes you had made to the server before you started it.

The member has now been restored to the group as a new member.

**Restoring a Primary Member.** If the restored member is a primary in the group, care must be taken to prevent writes to the restored database during the Group Replication recovery phase: Depending on how the group is accessed by clients, there is a possibility of DML statements being executed on the restored member once it becomes accessible on the network, prior to the member finishing its catch-up on the activities it has missed while off the group. To avoid this, *before starting the restored server*, configure the following system variables in the server option file:

```
group_replication_start_on_boot=OFF
super_read_only=ON
event_scheduler=OFF
```

These settings ensure that the member becomes read-only at startup and that the event scheduler is turned off while the member is catching up with the group during the recovery phase. Adequate error handling must also be configured on the clients, as they are prevented temporarily from performing DML operations during this period on the restored member. Once the restore process is fully completed and the restored member is in-sync with the rest of the group, revert those changes; restart the event scheduler:

```
mysql> SET global event_scheduler=ON;
```

Edit the following system variables in the member's option file, so things are correctly configured for the next startup:

```
group_replication_start_on_boot=ON
super_read_only=OFF
event_scheduler=ON
```

## 17.6 Group Replication Security

This section explains how to secure a group, securing the connections between members of a group, or by establishing a security perimeter using IP address allowlisting.

### 17.6.1 Group Replication IP Address Allowlisting

The Group Replication plugin has a configuration option to determine from which hosts an incoming Group Communication System connection can be accepted. This option is called

`group_replication_ip_whitelist`. If you set this option on a server s1, then when server s2 is establishing a connection to s1 for the purpose of engaging group communication, s1 first checks the allowlist before accepting the connection from s2. If s2 is in the allowlist, then s1 accepts the connection, otherwise s1 rejects the connection attempt by s2.

If you do not specify an allowlist explicitly, the group communication engine (XCom) automatically scans active interfaces on the host, and identifies those with addresses on private subnetworks. These addresses and the `localhost` IP address for IPv4 are used to create an automatic Group Replication allowlist. The automatic allowlist therefore includes any IP addresses found for the host in the following ranges:

```
10/8 prefix (10.0.0.0 - 10.255.255.255) - Class A
172.16/12 prefix (172.16.0.0 - 172.31.255.255) - Class B
192.168/16 prefix (192.168.0.0 - 192.168.255.255) - Class C
127.0.0.1 - localhost for IPv4
```

An entry is added to the error log stating the addresses that have been allowlisted automatically for the host.

The automatic allowlist of private addresses cannot be used for connections from servers outside the private network, so a server, even if it has interfaces on public IPs, does not by default allow Group Replication connections from external hosts. For Group Replication connections between server instances that are on different machines, you must provide public IP addresses and specify these as an explicit allowlist. If you specify any entries for the allowlist, the private and `localhost` addresses are not added automatically, so if you use any of these, you must specify them explicitly.

To specify an allowlist manually, use the `group_replication_ip_whitelist` option. You cannot change the allowlist on a server while it is an active member of a replication group. If the member is active, you must issue a `STOP GROUP_REPLICATION` statement before changing the allowlist, and a `START GROUP_REPLICATION` statement afterwards.

In the allowlist, you can specify any combination of the following:

- IPv4 addresses (for example, `198.51.100.44`)
- IPv4 addresses with CIDR notation (for example, `192.0.2.21/24`)
- Host names, from MySQL 5.7.21 (for example, `example.org`)
- Host names with CIDR notation, from MySQL 5.7.21 (for example, `www.example.com/24`)

IPv6 addresses, and host names that resolve to IPv6 addresses, are not supported in MySQL 5.7. You can use CIDR notation in combination with host names or IP addresses to allowlist a block of IP addresses with a particular network prefix, but do ensure that all the IP addresses in the specified subnet are under your control.

You must stop and restart Group Replication on a member in order to change its allowlist. A comma must separate each entry in the allowlist. For example:

```
mysql> STOP GROUP_REPLICATION;
mysql> SET GLOBAL group_replication_ip_whitelist="192.0.2.21/24,198.51.100.44,203.0.113.0/24,example.or
mysql> START GROUP_REPLICATION;
```

The allowlist must contain the IP address or host name that is specified in each member's `group_replication_local_address` system variable. This address is not the same as the MySQL server SQL protocol host and port, and is not specified in the `bind_address` system variable for the server instance.

When a replication group is reconfigured (for example, when a new primary is elected or a member joins or leaves), the group members re-establish connections between themselves. If a group member is only allowlisted by servers that are no longer part of the replication group after the reconfiguration,

it is unable to reconnect to the remaining servers in the replication group that do not allowlist it. To avoid this scenario entirely, specify the same allowlist for all servers that are members of the replication group.

#### Note

It is possible to configure different allowlists on different group members according to your security requirements, for example, in order to keep different subnets separate. If you need to configure different allowlists to meet your security requirements, ensure that there is sufficient overlap between the allowlists in the replication group to maximize the possibility of servers being able to reconnect in the absence of their original seed member.

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for allowlist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

#### Warning

Host names are inherently less secure than IP addresses in an allowlist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your allowlist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

## 17.6.2 Group Replication Secure Socket Layer (SSL) Support

Group communication connections as well as recovery connections, are secured using SSL. The following sections explain how to configure connections.

### Configuring SSL for Group Replication Recovery

Recovery is performed through a regular asynchronous replication connection. Once the donor is selected, the server joining the group establishes an asynchronous replication connection. This is all automatic.

However, a user that requires an SSL connection must have been created before the server joining the group connects to the donor. Typically, this is set up at the time one is provisioning a server to join the group.

```
donor> SET SQL_LOG_BIN=0;
donor> CREATE USER 'rec_ssl_user'@'%' REQUIRE SSL;
donor> GRANT replication slave ON *.* TO 'rec_ssl_user'@'%';
donor> SET SQL_LOG_BIN=1;
```

Assuming that all servers already in the group have a replication user set up to use SSL, you configure the server joining the group to use those credentials when connecting to the donor. That is done according to the values of the SSL options provided for the Group Replication plugin.

```
new_member> SET GLOBAL group_replication_recovery_use_ssl=1;
new_member> SET GLOBAL group_replication_recovery_ssl_ca= '....cacert.pem';
new_member> SET GLOBAL group_replication_recovery_ssl_cert= '..../client-cert.pem';
new_member> SET GLOBAL group_replication_recovery_ssl_key= '..../client-key.pem';
```

And by configuring the recovery channel to use the credentials of the user that requires an SSL connection.

```
new_member> CHANGE MASTER TO MASTER_USER="rec_ssl_user" FOR CHANNEL "group_replication_recovery";
```

```
new_member> START GROUP_REPLICATION;
```

## Configuring SSL for Group Communication

Secure sockets can be used to establish communication between members in a group. The configuration for this depends on the server's SSL configuration. As such, if the server has SSL configured, the Group Replication plugin also has SSL configured. For more information on the options for configuring the server SSL, see [Command Options for Encrypted Connections](#). The options which configure Group Replication are shown in the following table.

**Table 17.2 SSL Options**

| String Configuration    | Description                                                       |
|-------------------------|-------------------------------------------------------------------|
| <code>ssl_key</code>    | of key file. To be used as client and server certificate.         |
| <code>ssl_cert</code>   | of certificate file. To be used as client and server certificate. |
| <code>ssl_ca</code>     | of file with SSL Certificate Authorities that are trusted.        |
| <code>ssl_capath</code> | of directory containing certificates for SSL Certificate          |

|                                                                                   |
|-----------------------------------------------------------------------------------|
| <b>String</b>                                                                     |
| <b>Configuration</b>                                                              |
| <b>Description</b>                                                                |
| Authorities<br>that<br>are<br>trusted.                                            |
| <b>RevocationList</b>                                                             |
| of<br>file<br>containing<br>the<br>certificate<br>revocation<br>lists.            |
| <b>RevokedPath</b>                                                                |
| of<br>directory<br>containing<br>revoked<br>certificate<br>lists.                 |
| <b>Permitted</b>                                                                  |
| ciphers<br>to<br>use<br>while<br>encrypting<br>data<br>over<br>the<br>connection. |
| <b>Version</b>                                                                    |
| communication<br>uses<br>this<br>version<br>and<br>its<br>protocols.              |

These options are MySQL Server configuration options which Group Replication relies on for its configuration. In addition there is the following Group Replication specific option to configure SSL on the plugin itself.

- `group_replication_ssl_mode` - specifies the security state of the connection between Group Replication members.

**Table 17.3 group\_replication\_ssl\_mode configuration values**

|                                                                          |
|--------------------------------------------------------------------------|
| <b>Description</b>                                                       |
| <b>DISABLED</b><br>an<br>unencrypted<br>connection<br><i>(default)</i> . |

**Description****RESCUED**

a  
secure  
connection  
if  
the  
server  
supports  
secure  
connections.

**VERIFY\_CA**

REQUIRED,  
but  
additionally  
verify  
the  
server  
TLS  
certificate  
against  
the  
configured  
Certificate  
Authority  
(CA)  
certificates.

**VERIFY\_IDENTITY**

VERIFY\_CA,  
but  
additionally  
verify  
that  
the  
server  
certificate  
matches  
the  
host  
to  
which  
the  
connection  
is  
attempted.

The following example shows an example my.cnf file section used to configure SSL on a server and how activate it for Group Replication.

```
[mysqld]
ssl_ca = "cacert.pem"
ssl_capath = "/.../ca_directory"
ssl_cert = "server-cert.pem"
ssl_cipher = "DHE-RSA-AE512-SHA"
ssl_crl = "crl-server-revoked.crl"
ssl_crlpath = "/.../crl_directory"
ssl_key = "server-key.pem"
group_replication_ssl_mode= REQUIRED
```

The only plugin specific configuration option that is listed is `group_replication_ssl_mode`. This option activates the SSL communication between members of the group, by configuring the SSL framework with the `ssl_*` parameters that are provided to the server.

### 17.6.3 Group Replication and Virtual Private Networks (VPNs)

There is nothing preventing Group Replication from operating over a virtual private network. At its core, it just relies on an IPv4 socket to establish connections between servers for the purpose of propagating messages between them.

## 17.7 Group Replication System Variables

This section lists the system variables that are specific to the Group Replication plugin. Every configuration option is prefixed with "`group_replication`".

Most system variables for Group Replication are described as dynamic, and their values can be changed while the server is running. However, in most cases, the change only takes effect after you stop and restart Group Replication on the group member using a `STOP GROUP_REPLICATION` statement followed by a `START GROUP_REPLICATION` statement. Changes to the following system variables take effect without stopping and restarting Group Replication:

- `group_replication_exit_state_action`
- `group_replication_flow_control_applier_threshold`
- `group_replication_flow_control_certifier_threshold`
- `group_replication_flow_control_hold_percent`
- `group_replication_flow_control_max_commit_quota`
- `group_replication_flow_control_member_quota_percent`
- `group_replication_flow_control_min_quota`
- `group_replication_flow_control_min_recovery_quota`
- `group_replication_flow_control_mode`
- `group_replication_force_members`
- `group_replication_member_weight`
- `group_replication_transaction_size_limit`
- `group_replication_unreachable_majority_timeout`

Most system variables for Group Replication can have different values on different group members. For the following system variables, it is advisable to set the same value on all members of a group in order to avoid unnecessary rollback of transactions, failure of message delivery, or failure of message recovery:

- `group_replication_auto_increment_increment`
- `group_replication_compression_threshold`
- `group_replication_transaction_size_limit`

Some system variables on a Group Replication group member, including some Group Replication-specific system variables and some general system variables, are group-wide configuration settings. These system variables must have the same value on all group members, cannot be changed while Group Replication is running, and require a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. These conditions apply to the following system variables:

- `group_replication_single_primary_mode`
- `group_replication_enforce_update_everywhere_checks`
- `group_replication_gtid_assignment_block_size`
- `default_table_encryption`
- `lower_case_table_names`
- `transaction_write_set_extraction`

### Important

- A number of system variables for Group Replication are not completely validated during server startup if they are passed as command line arguments to the server. These system variables include `group_replication_group_name`, `group_replication_single_primary_mode`, `group_replication_force_members`, the SSL variables, and the flow control system variables. They are only fully validated after the server has started.
- System variables for Group Replication that specify IP addresses or host names for group members are not validated until a `START GROUP_REPLICATION` statement is issued. Group Replication's Group Communication System (GCS) is not available to validate the values until that point.

The system variables that are specific to the Group Replication plugin are as follows:

- `group_replication_allow_local_disjoint_gtids_join`

|                     |                                                                             |
|---------------------|-----------------------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-allow-local-disjoint-gtids-join[={OFF ON}]</code> |
| Introduced          | 5.7.17                                                                      |
| Deprecated          | 5.7.21                                                                      |
| System Variable     | <code>group_replication_allow_local_disjoint_gtids_join</code>              |
| Scope               | Global                                                                      |
| Dynamic             | Yes                                                                         |
| Type                | Boolean                                                                     |
| Default Value       | <code>OFF</code>                                                            |

Deprecated in version 5.7.21 and scheduled for removal in a future version. Allows the server to join the group even if it has local transactions that are not present in the group.

### Warning

Use caution when enabling this option as incorrect usage can lead to conflicts in the group and rollback of transactions. The option should only be enabled as a last resort method to allow a server that has local transactions to join an existing group, and then only if the local transactions do not affect the data that is handled by the group (for example, an administrative action that was written to the binary log). The option should not be left enabled on all group members.

- `group_replication_allow_local_lower_version_join`

|                     |                                                                            |
|---------------------|----------------------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-allow-local-lower-version-join[={OFF ON}]</code> |
| Introduced          | 5.7.17                                                                     |
| System Variable     | <code>group_replication_allow_local_lower_version_join</code>              |
| Scope               | Global                                                                     |
| Dynamic             | Yes                                                                        |
| Type                | Boolean                                                                    |
| Default Value       | <code>OFF</code>                                                           |

Allows the current server to join the group even if it has a lower major version than the group. With the default setting `OFF`, servers are not permitted to join a replication group if they have a lower major version than the existing group members. For example, a MySQL 5.7 server cannot join a group that consists of MySQL 8.0 servers. This standard policy ensures that all members of a group are able to exchange messages and apply transactions. Set `group_replication_allow_local_lower_version_join` to `ON` only in the following scenarios:

- A server must be added to the group in an emergency in order to improve the group's fault tolerance, and only older versions are available.
- You want to carry out a downgrade of the replication group members without shutting down the whole group and bootstrapping it again.

### Warning

Setting this option to `ON` does not make the new member compatible with the group, and allows it to join the group without any safeguards against incompatible behaviors by the existing members. To ensure the new member's correct operation, take *both* of the following precautions:

1. Before the server with the lower major version joins the group, stop all writes on that server.
2. From the point where the server with the lower major version joins the group, stop all writes on the other servers in the group.

Without these precautions, the server with the lower major version is likely to experience difficulties and terminate with an error.

- `group_replication_auto_increment_increment`

|                     |                                                             |
|---------------------|-------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-auto-increment-increment=#</code> |
| Introduced          | 5.7.17                                                      |
| System Variable     | <code>group_replication_auto_increment_increment</code>     |
| Scope               | Global                                                      |
| Dynamic             | Yes                                                         |
| Type                | Integer                                                     |
| Default Value       | <code>7</code>                                              |
| Minimum Value       | <code>1</code>                                              |
| Maximum Value       | <code>65535</code>                                          |

Determines the interval between successive column values for transactions that execute on this server instance. This system variable should have the same value on all group members.

When Group Replication is started on a server, the value of the server system variable `auto_increment_increment` is changed to this value, and the value of the server system variable `auto_increment_offset` is changed to the server ID. These settings avoid the selection of duplicate auto-increment values for writes on group members, which causes rollback of transactions. The changes are reverted when Group Replication is stopped. These changes are only made and reverted if `auto_increment_increment` and `auto_increment_offset` each have their default value of 1. If their values have already been modified from the default, Group Replication does not alter them. From MySQL 8.0, the system variables are also not modified when Group Replication is in single-primary mode, where only one server writes.

The default value of 7 represents a balance between the number of usable values and the permitted maximum size of a replication group (9 members). If your group has more or fewer members, you can set this system variable to match the expected number of group members before Group Replication is started. You cannot change the setting while Group Replication is running.

- `group_replication_bootstrap_group`

|                     |                                                             |
|---------------------|-------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-bootstrap-group[={OFF ON}]</code> |
| Introduced          | 5.7.17                                                      |
| System Variable     | <code>group_replication_bootstrap_group</code>              |
| Scope               | Global                                                      |
| Dynamic             | Yes                                                         |
| Type                | Boolean                                                     |
| Default Value       | <code>OFF</code>                                            |

Configure this server to bootstrap the group. This option must only be set on one server and only when starting the group for the first time or restarting the entire group. After the group has been bootstrapped, set this option to `OFF`. It should be set to `OFF` both dynamically and in the configuration files. Starting two servers or restarting one server with this option set while the group is running may lead to an artificial split brain situation, where two independent groups with the same name are bootstrapped.

- `group_replication_components_stop_timeout`

|                     |                                                            |
|---------------------|------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-components-stop-timeout=#</code> |
| Introduced          | 5.7.17                                                     |
| System Variable     | <code>group_replication_components_stop_timeout</code>     |
| Scope               | Global                                                     |
| Dynamic             | Yes                                                        |
| Type                | Integer                                                    |
| Default Value       | <code>31536000</code>                                      |
| Minimum Value       | <code>2</code>                                             |
| Maximum Value       | <code>31536000</code>                                      |
| Unit                | <code>seconds</code>                                       |

Timeout, in seconds, that Group Replication waits for each of the components when shutting down.

- `group_replication_compression_threshold`

|                     |                                                          |
|---------------------|----------------------------------------------------------|
| Command-Line Format | <code>--group-replication-compression-threshold=#</code> |
| Introduced          | 5.7.17                                                   |
| System Variable     | <code>group_replication_compression_threshold</code>     |

|               |            |
|---------------|------------|
| Scope         | Global     |
| Dynamic       | Yes        |
| Type          | Integer    |
| Default Value | 1000000    |
| Minimum Value | 0          |
| Maximum Value | 4294967295 |
| Unit          | bytes      |

- The threshold value in bytes above which compression is applied to messages sent between group members. If this system variable is set to zero, compression is disabled. The value of `group_replication_compression_threshold` should be the same on all group members.

Group Replication uses the LZ4 compression algorithm to compress messages sent in the group. Note that the maximum supported input size for the LZ4 compression algorithm is 2113929216 bytes. This limit is lower than the maximum possible value for the `group_replication_compression_threshold` system variable, which is matched to the maximum message size accepted by XCom. With the LZ4 compression algorithm, do not set a value greater than 2113929216 bytes for `group_replication_compression_threshold`, because transactions above this size cannot be committed when message compression is enabled.

For more information, see [Section 17.9.7.2, “Message Compression”](#).

- `group_replication_enforce_update_everywhere_checks`

|                     |                                                                              |
|---------------------|------------------------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-enforce-update-everywhere-checks[={OFF ON}]</code> |
| Introduced          | 5.7.17                                                                       |
| System Variable     | <code>group_replication_enforce_update_everywhere_checks</code>              |
| Scope               | Global                                                                       |
| Dynamic             | Yes                                                                          |
| Type                | Boolean                                                                      |
| Default Value       | OFF                                                                          |

Enable or disable strict consistency checks for multi-primary update everywhere. The default is that checks are disabled. In single-primary mode, this option must be disabled on all group members. In multi-primary mode, when this option is enabled, statements are checked as follows to ensure they are compatible with multi-primary mode:

- If a transaction is executed under the `SERIALIZABLE` isolation level, then its commit fails when synchronizing itself with the group.
- If a transaction executes against a table that has foreign keys with cascading constraints, then the transaction fails to commit when synchronizing itself with the group.

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect.

- `group_replication_exit_state_action`

|                     |                                                          |
|---------------------|----------------------------------------------------------|
| Command-Line Format | <code>--group-replication-exit-state-action=value</code> |
| Introduced          | 5.7.24                                                   |
| System Variable     | <code>group_replication_exit_state_action</code>         |

|               |                               |
|---------------|-------------------------------|
| Scope         | Global                        |
| Dynamic       | Yes                           |
| Type          | Enumeration                   |
| Default Value | READ_ONLY                     |
| Valid Values  | ABORT_SERVER<br><br>READ_ONLY |

Configures how Group Replication behaves when a server instance leaves the group unintentionally, for example after encountering an applier error, or in the case of a loss of majority, or when another member of the group expels it due to a suspicion timing out. The timeout period for a member to leave the group in the case of a loss of majority is set by the `group_replication_unreachable_majority_timeout` system variable. Note that an expelled group member does not know that it was expelled until it reconnects to the group, so the specified action is only taken if the member manages to reconnect, or if the member raises a suspicion on itself and expels itself.

- When `group_replication_exit_state_action` is set to `ABORT_SERVER`, if the member exits the group unintentionally, the instance shuts down MySQL.

When `group_replication_exit_state_action` is set to `READ_ONLY`, if the member exits the group unintentionally, the instance switches MySQL to super read only mode (by setting the system variable `super_read_only` to `ON`). This setting is the default in MySQL 5.7.

#### Important

If a failure occurs before the member has successfully joined the group, the specified exit action *is not taken*. This is the case if there is a failure during the local configuration check, or a mismatch between the configuration of the joining member and the configuration of the group. In these situations, the `super_read_only` system variable is left with its original value, and the server does not shut down MySQL. To ensure that the server cannot accept updates when Group Replication did not start, we therefore recommend that `super_read_only=ON` is set in the server's configuration file at startup, which Group Replication changes to `OFF` on primary members after it has been started successfully. This safeguard is particularly important when the server is configured to start Group Replication on server boot (`group_replication_start_on_boot=ON`), but it is also useful when Group Replication is started manually using a `START GROUP_REPLICATION` command.

If a failure occurs after the member has successfully joined the group, the specified exit action *is taken*. This is the case if there is an applier error, if the member is expelled from the group, or if the member is set to time out in the event of an unreachable majority. In these situations, if `READ_ONLY` is the exit action, the `super_read_only` system variable is set to `ON`, or if `ABORT_SERVER` is the exit action, the server shuts down MySQL.

**Table 17.4 Exit actions in Group Replication failure situations**

| Failure situation                      | Group Replication started with <code>START GROUP_REPLICATION</code> | Group Replication started with <code>group_replication_start_on_boot=ON</code> |
|----------------------------------------|---------------------------------------------------------------------|--------------------------------------------------------------------------------|
| Member fails local configuration check | <code>super_read_only</code> unchanged<br>MySQL continues running   | <code>super_read_only</code> unchanged<br>MySQL continues running              |

| Failure situation                                                                                 | <b>Group Replication started with <code>START GROUP_REPLICATION</code></b>    | <b>Group Replication started with <code>group_replication_start_on_boot =ON</code></b> |
|---------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| OR<br>Mismatch between joining member and group configuration                                     | Set <code>super_read_only=ON</code> at startup to prevent updates             | Set <code>super_read_only=ON</code> at startup to prevent updates (Important)          |
| Applier error on member<br>OR<br>Member expelled from group<br>OR<br>Unreachable majority timeout | <code>super_read_only</code> set to <code>ON</code><br>OR<br>MySQL shuts down | <code>super_read_only</code> set to <code>ON</code><br>OR<br>MySQL shuts down          |

- `group_replication_flow_control_applier_threshold`

|                     |                                                                   |
|---------------------|-------------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-flow-control-applier-threshold=#</code> |
| Introduced          | 5.7.17                                                            |
| System Variable     | <code>group_replication_flow_control_applier_threshold</code>     |
| Scope               | Global                                                            |
| Dynamic             | Yes                                                               |
| Type                | Integer                                                           |
| Default Value       | 25000                                                             |
| Minimum Value       | 0                                                                 |
| Maximum Value       | 2147483647                                                        |
| Unit                | <code>transactions</code>                                         |

Specifies the number of waiting transactions in the applier queue that trigger flow control. This variable can be changed without resetting Group Replication.

- `group_replication_flow_control_certifier_threshold`

|                     |                                                                     |
|---------------------|---------------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-flow-control-certifier-threshold=#</code> |
| Introduced          | 5.7.17                                                              |
| System Variable     | <code>group_replication_flow_control_certifier_threshold</code>     |
| Scope               | Global                                                              |
| Dynamic             | Yes                                                                 |
| Type                | Integer                                                             |
| Default Value       | 25000                                                               |
| Minimum Value       | 0                                                                   |
| Maximum Value       | 2147483647                                                          |

|      |                           |
|------|---------------------------|
| Unit | <code>transactions</code> |
|------|---------------------------|

Specifies the number of waiting transactions in the certifier queue that trigger flow control. This variable can be changed without resetting Group Replication.

- `group_replication_flow_control_hold_percent`

|                     |                                                              |
|---------------------|--------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-flow-control-hold-percent=#</code> |
| System Variable     | <code>group_replication_flow_control_hold_percent</code>     |
| Scope               | Global                                                       |
| Dynamic             | Yes                                                          |
| Type                | Integer                                                      |
| Default Value       | 10                                                           |
| Minimum Value       | 0                                                            |
| Maximum Value       | 100                                                          |
| Unit                | <code>percentage</code>                                      |

Defines what percentage of the group quota remains unused to allow a cluster under flow control to catch up on backlog. A value of 0 implies that no part of the quota is reserved for catching up on the work backlog.

- `group_replication_flow_control_max_commit_quota`

|                     |                                                                  |
|---------------------|------------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-flow-control-max-commit-quota=#</code> |
| System Variable     | <code>group_replication_flow_control_max_commit_quota</code>     |
| Scope               | Global                                                           |
| Dynamic             | Yes                                                              |
| Type                | Integer                                                          |
| Default Value       | 0                                                                |
| Minimum Value       | 0                                                                |
| Maximum Value       | 2147483647                                                       |

Defines the maximum flow control quota of the group, or the maximum available quota for any period while flow control is enabled. A value of 0 implies that there is no maximum quota set. Cannot be smaller than `group_replication_flow_control_min_quota` and `group_replication_flow_control_min_recovery_quota`.

- `group_replication_flow_control_member_quota_percent`

|                     |                                                                      |
|---------------------|----------------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-flow-control-member-quota-percent=#</code> |
| System Variable     | <code>group_replication_flow_control_member_quota_percent</code>     |
| Scope               | Global                                                               |
| Dynamic             | Yes                                                                  |
| Type                | Integer                                                              |
| Default Value       | 0                                                                    |
| Minimum Value       | 0                                                                    |
| Maximum Value       | 100                                                                  |

|      |            |
|------|------------|
| Unit | percentage |
|------|------------|

Defines the percentage of the quota that a member should assume is available for itself when calculating the quotas. A value of 0 implies that the quota should be split equally between members that were writers in the last period.

- [group\\_replication\\_flow\\_control\\_min\\_quota](#)

|                     |                                                          |
|---------------------|----------------------------------------------------------|
| Command-Line Format | --group-replication-flow-control-min-quota=#             |
| System Variable     | <a href="#">group_replication_flow_control_min_quota</a> |
| Scope               | Global                                                   |
| Dynamic             | Yes                                                      |
| Type                | Integer                                                  |
| Default Value       | 0                                                        |
| Minimum Value       | 0                                                        |
| Maximum Value       | 2147483647                                               |

Controls the lowest flow control quota that can be assigned to a member, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. Cannot be larger than [group\\_replication\\_flow\\_control\\_max\\_commit\\_quota](#).

- [group\\_replication\\_flow\\_control\\_min\\_recovery\\_quota](#)

|                     |                                                                   |
|---------------------|-------------------------------------------------------------------|
| Command-Line Format | --group-replication-flow-control-min-recovery-quota=#             |
| System Variable     | <a href="#">group_replication_flow_control_min_recovery_quota</a> |
| Scope               | Global                                                            |
| Dynamic             | Yes                                                               |
| Type                | Integer                                                           |
| Default Value       | 0                                                                 |
| Minimum Value       | 0                                                                 |
| Maximum Value       | 2147483647                                                        |

Controls the lowest quota that can be assigned to a member because of another recovering member in the group, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. Cannot be larger than [group\\_replication\\_flow\\_control\\_max\\_commit\\_quota](#).

- [group\\_replication\\_flow\\_control\\_mode](#)

|                     |                                                     |
|---------------------|-----------------------------------------------------|
| Command-Line Format | --group-replication-flow-control-mode=value         |
| Introduced          | 5.7.17                                              |
| System Variable     | <a href="#">group_replication_flow_control_mode</a> |
| Scope               | Global                                              |
| Dynamic             | Yes                                                 |

**QUOTA**

Specifies the mode used for flow control. This variable can be changed without resetting Group Replication.

- [group\\_replication\\_force\\_members](#)

|                     |                                                      |
|---------------------|------------------------------------------------------|
| Command-Line Format | <code>--group-replication-force-members=value</code> |
| Introduced          | 5.7.17                                               |
| System Variable     | <code>group_replication_force_members</code>         |
| Scope               | Global                                               |
| Dynamic             | Yes                                                  |
| Type                | String                                               |

A list of peer addresses as a comma separated list such as `host1:port1,host2:port2`. This option is used to force a new group membership, in which the excluded members do not receive a new view and are blocked. (You need to manually kill the excluded servers.) Any invalid host names in the list could cause this action to fail because they could block group membership. For a description of the procedure to follow, see [Section 17.5.3, “Network Partitioning”](#).

You must specify the address or host name and port as they are given in the `group_replication_local_address` option for each member. For example:

```
"198.51.100.44:33061,example.org:33061"
```

After you have used the `group_replication_force_members` system variable to successfully force a new group membership and unblock the group, ensure that you clear the system variable. `group_replication_force_members` must be empty in order to issue a `START GROUP_REPLICATION` statement.

- [group\\_replication\\_group\\_name](#)

|                     |                                                   |
|---------------------|---------------------------------------------------|
| Command-Line Format | <code>--group-replication-group-name=value</code> |

| System Variable     | <code>group_replication_group_name</code>         |
| Scope               | Global                                            |
| Dynamic             | Yes                                               |
| Type                | String                                            |

The name of the group which this server instance belongs to. Must be a valid UUID. This UUID is used internally when setting GTIDs for Group Replication events in the binary log.

**Important**

A unique UUID must be used.

- [group\\_replication\\_group\\_seeds](#)

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--group-replication-group-seeds=value</code> |
| Introduced          | 5.7.17                                             |
| System Variable     | <code>group_replication_group_seeds</code>         |
| Scope               | Global                                             |
| Dynamic             | Yes                                                |

|      |        |
|------|--------|
| Type | String |
|------|--------|

A list of group members to which a joining member can connect to obtain details of all the current group members. The joining member uses these details to select and connect to a group member to obtain the data needed for synchrony with the group. The list consists of the seed member's network addresses specified as a comma separated list, such as `host1:port1,host2:port2`.

### Important

These addresses must not be the member's SQL hostname and port.

Note that the value you specify for this variable is not validated until a `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

Usually this list consists of all members of the group, but you can choose a subset of the group members to be seeds. The list must contain at least one valid member address. Each address is validated when starting Group Replication. If the list does not contain any valid host names, issuing `START GROUP_REPLICATION` fails.

- `group_replication_gtid_assignment_block_size`

|                                  |                                                               |
|----------------------------------|---------------------------------------------------------------|
| Command-Line Format              | <code>--group-replication-gtid-assignment-block-size=#</code> |
| Introduced                       | 5.7.17                                                        |
| System Variable                  | <code>group_replication_gtid_assignment_block_size</code>     |
| Scope                            | Global                                                        |
| Dynamic                          | Yes                                                           |
| Type                             | Integer                                                       |
| Default Value                    | <code>1000000</code>                                          |
| Minimum Value                    | <code>1</code>                                                |
| Maximum Value (64-bit platforms) | <code>9223372036854775807</code>                              |
| Maximum Value (32-bit platforms) | <code>4294967295</code>                                       |

The number of consecutive GTIDs that are reserved for each member. Each member consumes its blocks and reserves more when needed.

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect.

- `group_replication_ip_whitelist`

|                     |                                                     |
|---------------------|-----------------------------------------------------|
| Command-Line Format | <code>--group-replication-ip-whitelist=value</code> |
| Introduced          | 5.7.17                                              |
| System Variable     | <code>group_replication_ip_whitelist</code>         |
| Scope               | Global                                              |
| Dynamic             | Yes                                                 |
| Type                | String                                              |

|               |                        |
|---------------|------------------------|
| Default Value | <code>AUTOMATIC</code> |
|---------------|------------------------|

Specifies the allowlist of hosts that are permitted to connect to the group. The address that you specify for each group member in `group_replication_local_address` must be allowlisted on the other servers in the replication group. Note that the value you specify for this variable is not validated until a `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

By default, this system variable is set to `AUTOMATIC`, which permits connections from private subnetworks active on the host. The group communication engine (XCom) automatically scans active interfaces on the host, and identifies those with addresses on private subnetworks. These addresses and the `localhost` IP address for IPv4 are used to create the Group Replication allowlist. For a list of the ranges from which addresses are automatically allowlisted, see [Section 17.6.1, “Group Replication IP Address Allowlisting”](#).

The automatic allowlist of private addresses cannot be used for connections from servers outside the private network. For Group Replication connections between server instances that are on different machines, you must provide public IP addresses and specify these as an explicit allowlist. If you specify any entries for the allowlist, the private addresses are not added automatically, so if you use any of these, you must specify them explicitly. The `localhost` IP address is added automatically.

As the value of the `group_replication_ip_whitelist` option, you can specify any combination of the following:

- IPv4 addresses (for example, `198.51.100.44`)
- IPv4 addresses with CIDR notation (for example, `192.0.2.21/24`)
- Host names, from MySQL 5.7.21 (for example, `example.org`)
- Host names with CIDR notation, from MySQL 5.7.21 (for example, `www.example.com/24`)

IPv6 addresses, and host names that resolve to IPv6 addresses, are not supported in MySQL 5.7. You can use CIDR notation in combination with host names or IP addresses to allowlist a block of IP addresses with a particular network prefix, but do ensure that all the IP addresses in the specified subnet are under your control.

A comma must separate each entry in the allowlist. For example:

```
192.0.2.22,198.51.100.0/24,example.org,www.example.com/24
```

It is possible to configure different allowlists on different group members according to your security requirements, for example, in order to keep different subnets separate. However, this can cause issues when a group is reconfigured. If you do not have a specific security requirement to do otherwise, use the same allowlist on all members of a group. For more details, see [Section 17.6.1, “Group Replication IP Address Allowlisting”](#).

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for allowlist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

### Warning

Host names are inherently less secure than IP addresses in an allowlist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your allowlist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can

also implement name resolution locally using the hosts file, to avoid the use of external components.

- `group_replication_local_address`

|                     |                                                      |
|---------------------|------------------------------------------------------|
| Command-Line Format | <code>--group-replication-local-address=value</code> |
| Introduced          | 5.7.17                                               |
| System Variable     | <code>group_replication_local_address</code>         |
| Scope               | Global                                               |
| Dynamic             | Yes                                                  |
| Type                | String                                               |

The network address which the member provides for connections from other members, specified as a `host:port` formatted string. This address must be reachable by all members of the group because it is used by the group communication engine for Group Replication (XCom, a Paxos variant) for TCP communication between remote XCom instances. Communication with the local instance is over an input channel using shared memory.

### Warning

Do not use this address for communication with the member.

Other Group Replication members contact this member through this `host:port` for all internal group communication. This is not the MySQL server SQL protocol host and port.

The address or host name that you specify in `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. You can use the same port for all members of a replication group as long as the host names or IP addresses are all different, and you can use the same host name or IP address for all members as long as the ports are all different. The recommended port for `group_replication_local_address` is 33061. Note that the value you specify for this variable is not validated until the `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

- `group_replication_member_weight`

|                     |                                                  |
|---------------------|--------------------------------------------------|
| Command-Line Format | <code>--group-replication-member-weight=#</code> |
| Introduced          | 5.7.20                                           |
| System Variable     | <code>group_replication_member_weight</code>     |
| Scope               | Global                                           |
| Dynamic             | Yes                                              |
| Type                | Integer                                          |
| Default Value       | 50                                               |
| Minimum Value       | 0                                                |
| Maximum Value       | 100                                              |
| Unit                | percentage                                       |

A percentage weight that can be assigned to members to influence the chance of the member being elected as primary in the event of failover, for example when the existing primary leaves a single-primary group. Assign numeric weights to members to ensure that specific members are elected, for

example during scheduled maintenance of the primary or to ensure certain hardware is prioritized in the event of failover.

For a group with members configured as follows:

- `member-1`: `group_replication_member_weight=30, server_uuid=aaaa`
- `member-2`: `group_replication_member_weight=40, server_uuid=bbbb`
- `member-3`: `group_replication_member_weight=40, server_uuid=cccc`
- `member-4`: `group_replication_member_weight=40, server_uuid=dddd`

during election of a new primary the members above would be sorted as `member-2`, `member-3`, `member-4`, and `member-1`. This results in `member-2` being chosen as the new primary in the event of failover. For more information, see [Section 17.5.1.1, “Single-Primary Mode”](#).

- `group_replication_poll_spin_loops`

|                                  |                                                    |
|----------------------------------|----------------------------------------------------|
| Command-Line Format              | <code>--group-replication-poll-spin-loops=#</code> |
| Introduced                       | 5.7.17                                             |
| System Variable                  | <code>group_replication_poll_spin_loops</code>     |
| Scope                            | Global                                             |
| Dynamic                          | Yes                                                |
| Type                             | Integer                                            |
| Default Value                    | 0                                                  |
| Minimum Value                    | 0                                                  |
| Maximum Value (64-bit platforms) | 18446744073709551615                               |
| Maximum Value (32-bit platforms) | 4294967295                                         |

The number of times the group communication thread waits for the communication engine mutex to be released before the thread waits for more incoming network messages.

- `group_replication_recovery_retry_count`

|                     |                                                         |
|---------------------|---------------------------------------------------------|
| Command-Line Format | <code>--group-replication-recovery-retry-count=#</code> |
| Introduced          | 5.7.17                                                  |
| System Variable     | <code>group_replication_recovery_retry_count</code>     |
| Scope               | Global                                                  |
| Dynamic             | Yes                                                     |
| Type                | Integer                                                 |
| Default Value       | 10                                                      |
| Minimum Value       | 0                                                       |
| Maximum Value       | 31536000                                                |

The number of times that the member that is joining tries to connect to the available donors before giving up.

- `group_replication_recovery_reconnect_interval`

|                     |                                                                |
|---------------------|----------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-recovery-reconnect-interval=#</code> |
|---------------------|----------------------------------------------------------------|

|                 |                                                               |
|-----------------|---------------------------------------------------------------|
| Introduced      | 5.7.17                                                        |
| System Variable | <a href="#">group_replication_recovery_reconnect_interval</a> |
| Scope           | Global                                                        |
| Dynamic         | Yes                                                           |

| Dynamic             | Yes                                                                         |
| Type                | Boolean                                                                     |
| Default Value       | <code>OFF</code>                                                            |

Make the recovery process check the server's Common Name value in the donor sent certificate.

- `group_replication_recovery_complete_at`

|                     |                                                                          |
|---------------------|--------------------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-recovery-complete-at=value</code>              |
| Introduced          | 5.7.17                                                                   |
| System Variable     | <code>group_replication_recovery_complete_at</code>                      |
| Scope               | Global                                                                   |
| Dynamic             | Yes                                                                      |
| Type                | Enumeration                                                              |
| Default Value       | <code>TRANSACTIONS_APPLIED</code>                                        |
| Valid Values        | <code>TRANSACTIONS_CERTIFIED</code><br><code>TRANSACTIONS_APPLIED</code> |

Recovery policies when handling cached transactions after state transfer. This option specifies whether a member is marked online after it has received all transactions that it missed before it joined the group (`TRANSACTIONS_CERTIFIED`) or after it has received and applied them (`TRANSACTIONS_APPLIED`).

- `group_replication_single_primary_mode`

|                     |                                                                 |
|---------------------|-----------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-single-primary-mode[={OFF ON}]</code> |
| Introduced          | 5.7.17                                                          |
| System Variable     | <code>group_replication_single_primary_mode</code>              |
| Scope               | Global                                                          |
| Dynamic             | Yes                                                             |
| Type                | Boolean                                                         |
| Default Value       | <code>ON</code>                                                 |

Instructs the group to automatically pick a single server to be the one that handles read/write workload. This server is the PRIMARY and all others are SECONDARIES.

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect.

- `group_replication_ssl_mode`

|                     |                                                                                                          |
|---------------------|----------------------------------------------------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-ssl-mode=value</code>                                                          |
| Introduced          | 5.7.17                                                                                                   |
| System Variable     | <code>group_replication_ssl_mode</code>                                                                  |
| Scope               | Global                                                                                                   |
| Dynamic             | Yes                                                                                                      |
| Type                | Enumeration                                                                                              |
| Default Value       | <code>DISABLED</code>                                                                                    |
| Valid Values        | <code>DISABLED</code><br><code>REQUIRED</code><br><code>VERIFY_CA</code><br><code>VERIFY_IDENTITY</code> |

Specifies the security state of the connection between Group Replication members.

- `group_replication_start_on_boot`

|                     |                                                           |
|---------------------|-----------------------------------------------------------|
| Command-Line Format | <code>--group-replication-start-on-boot[={OFF ON}]</code> |
| Introduced          | 5.7.17                                                    |
| System Variable     | <code>group_replication_start_on_boot</code>              |
| Scope               | Global                                                    |
| Dynamic             | Yes                                                       |
| Type                | Boolean                                                   |
| Default Value       | <code>ON</code>                                           |

Whether the server should start Group Replication or not during server start.

- `group_replication_transaction_size_limit`

|                     |                                                           |
|---------------------|-----------------------------------------------------------|
| Command-Line Format | <code>--group-replication-transaction-size-limit=#</code> |
| Introduced          | 5.7.19                                                    |
| System Variable     | <code>group_replication_transaction_size_limit</code>     |
| Scope               | Global                                                    |
| Dynamic             | Yes                                                       |
| Type                | Integer                                                   |
| Default Value       | <code>0</code>                                            |
| Minimum Value       | <code>0</code>                                            |
| Maximum Value       | <code>2147483647</code>                                   |
| Unit                | <code>bytes</code>                                        |

Configures the maximum transaction size in bytes which the replication group accepts. Transactions larger than this size are rolled back by the receiving member and are not broadcast to the group. Large transactions can cause problems for a replication group in terms of memory allocation, which

can cause the system to slow down, or in terms of network bandwidth consumption, which can cause a member to be suspected of having failed because it is busy processing the large transaction.

When this system variable is set to 0, which is the default in MySQL 5.7, there is no limit to the size of transactions the group accepts. From MySQL 8.0, the default setting for this system variable is 150000000 bytes (approximately 143 MB). Adjust the value of this system variable depending on the maximum message size that you need the group to tolerate, bearing in mind that the time taken to process a transaction is proportional to its size. The value of `group_replication_transaction_size_limit` should be the same on all group members. For further mitigation strategies for large transactions, see [Section 17.3.2, “Group Replication Limitations”](#).

- `group_replication_unreachable_majority_timeout`

|                     |                                                                 |
|---------------------|-----------------------------------------------------------------|
| Command-Line Format | <code>--group-replication-unreachable-majority-timeout=#</code> |
| Introduced          | 5.7.19                                                          |
| System Variable     | <code>group_replication_unreachable_majority_timeout</code>     |
| Scope               | Global                                                          |
| Dynamic             | Yes                                                             |
| Type                | Integer                                                         |
| Default Value       | 0                                                               |
| Minimum Value       | 0                                                               |
| Maximum Value       | 31536000                                                        |
| Unit                | seconds                                                         |

Configures how long members that suffer a network partition and cannot connect to the majority wait before leaving the group.

In a group of 5 servers (S1,S2,S3,S4,S5), if there is a disconnection between (S1,S2) and (S3,S4,S5) there is a network partition. The first group (S1,S2) is now in a minority because it cannot contact more than half of the group. While the majority group (S3,S4,S5) remains running, the minority group waits for the specified time for a network reconnection. Any transactions processed by the minority group are blocked until Group Replication is stopped using `STOP GROUP REPLICATION` on the members of the minority. Note that `group_replication_unreachable_majority_timeout` has no effect if it is set on the servers in the minority group after the loss of majority has been detected.

By default, this system variable is set to 0, which means that members that find themselves in a minority due to a network partition wait forever to leave the group. If configured to a number of seconds, members wait for this amount of time after losing contact with the majority of members before leaving the group. When the specified time elapses, all pending transactions processed by the minority are rolled back, and the servers in the minority partition move to the `ERROR` state. These servers then follow the action specified by the system variable `group_replication_exit_state_action`, which can be to set themselves to super read only mode or shut down MySQL.

### Warning

When you have a symmetric group, with just two members for example (S0,S2), if there is a network partition and there is no majority, after the configured timeout all members enter `ERROR` state.

## Group Replication Status Variable

This section describes the status variables which provide information about Group Replication. The variable has the following meaning:

- `group_replication_primary_member`

Shows the primary member's UUID when the group is operating in single-primary mode. If the group is operating in multi-primary mode, shows an empty string. See [Section 17.5.1.3, “Finding the Primary”](#).

## 17.8 Frequently Asked Questions

This section provides answers to frequently asked questions.

### What is the maximum number of MySQL servers in a group?

A group can consist of maximum 9 servers. Attempting to add another server to a group with 9 members causes the request to join to be refused. This limit has been identified from testing and benchmarking as a safe boundary where the group performs reliably on a stable local area network.

### How are servers in a group connected?

Servers in a group connect to the other servers in the group by opening a peer-to-peer TCP connection. These connections are only used for internal communication and message passing between servers in the group. This address is configured by the `group_replication_local_address` variable.

### What is the `group_replication_bootstrap_group` option used for?

The bootstrap flag instructs a member to *create* a group and act as the initial seed server. The second member joining the group needs to ask the member that bootstrapped the group to dynamically change the configuration in order for it to be added to the group.

A member needs to bootstrap the group in two scenarios. When the group is originally created, or when shutting down and restarting the entire group.

### How do I set credentials for the recovery procedure?

You pre-configure the Group Replication recovery channel credentials using the `CHANGE MASTER TO` statement.

### Can I scale-out my write-load using Group Replication?

Not directly, but MySQL Group replication is a shared nothing full replication solution, where all servers in the group replicate the same amount of data. Therefore if one member in the group writes N bytes to storage as the result of a transaction commit operation, then roughly N bytes are written to storage on other members as well, because the transaction is replicated everywhere.

However, given that other members do not have to do the same amount of processing that the original member had to do when it originally executed the transaction, they apply the changes faster. Transactions are replicated in a format that is used to apply row transformations only, without having to re-execute transactions again (row-based format).

Furthermore, given that changes are propagated and applied in row-based format, this means that they are received in an optimized and compact format, and likely reducing the number of IO operations required when compared to the originating member.

To summarize, you can scale-out processing, by spreading conflict free transactions throughout different members in the group. And you can likely scale-out a small fraction of your IO operations, since remote servers receive only the necessary changes to read-modify-write changes to stable storage.

Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

## Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

Some additional load is expected because servers need to be constantly interacting with each other for synchronization purposes. It is difficult to quantify how much more data. It also depends on the size of the group (three servers puts less stress on the bandwidth requirements than nine servers in the group).

Also the memory and CPU footprint are larger, because more complex work is done for the server synchronization part and for the group messaging.

## Can I deploy Group Replication across wide-area networks?

Yes, but the network connection between each member *must* be reliable and have suitable performance. Low latency, high bandwidth network connections are a requirement for optimal performance.

If network bandwidth alone is an issue, then [Section 17.9.7.2, “Message Compression”](#) can be used to lower the bandwidth required. However, if the network drops packets, leading to re-transmissions and higher end-to-end latency, throughput and latency are both negatively affected.

### Warning

When the network round-trip time (RTT) between any group members is 5 seconds or more you could encounter problems as the built-in failure detection mechanism could be incorrectly triggered.

## Do members automatically rejoin a group in case of temporary connectivity problems?

This depends on the reason for the connectivity problem. If the connectivity problem is transient and the reconnection is quick enough that the failure detector is not aware of it, then the server may not be removed from the group. If it is a "long" connectivity problem, then the failure detector eventually suspects a problem and the server is removed from the group.

Once a server is removed from the group, you need to join it back again. In other words, after a server is removed explicitly from the group you need to rejoin it manually (or have a script doing it automatically).

## When is a member excluded from a group?

If the member becomes silent, the other members remove it from the group configuration. In practice this may happen when the member has crashed or there is a network disconnection.

The failure is detected after a given timeout elapses for a given member and a new configuration without the silent member in it is created.

## What happens when one node is significantly lagging behind?

There is no method for defining policies for when to expel members automatically from the group. You need to find out why a member is lagging behind and fix that or remove the member from the group. Otherwise, if the server is so slow that it triggers the flow control, then the entire group slows down as well. The flow control can be configured according to your needs.

## Upon suspicion of a problem in the group, is there a special member responsible for triggering a reconfiguration?

No, there is no special member in the group in charge of triggering a reconfiguration.

Any member can suspect that there is a problem. All members need to (automatically) agree that a given member has failed. One member is in charge of expelling it from the group, by triggering a reconfiguration. Which member is responsible for expelling the member is not something you can control or set.

## Can I use Group Replication for sharding?

Group Replication is designed to provide highly available replica sets; data and writes are duplicated on each member in the group. For scaling beyond what a single system can provide, you need an orchestration and sharding framework built around a number of Group Replication sets, where each replica set maintains and manages a given shard or partition of your total dataset. This type of setup, often called a “sharded cluster”, allows you to scale reads and writes linearly and without limit.

## How do I use Group Replication with SELinux?

If SELinux is enabled, which you can verify using `sestatus -v`, then you need to enable the use of the Group Replication communication port. See [Setting the TCP Port Context for Group Replication](#).

## How do I use Group Replication with iptables?

If `iptables` is enabled, then you need to open up the Group Replication port for communication between the machines. To see the current rules in place on each machine, issue `iptables -L`. Assuming the port configured is 33061, enable communication over the necessary port by issuing `iptables -A INPUT -p tcp --dport 33061 -j ACCEPT`.

## How do I recover the relay log for a replication channel used by a group member?

The replication channels used by Group Replication behave in the same way as replication channels used in source to replica replication, and as such rely on the relay log. In the event of a change of the `relay_log` variable, or when the option is not set and the host name changes, there is a chance of errors. See [Section 16.2.4.1, “The Relay Log”](#) for a recovery procedure in this situation. Alternatively, another way of fixing the issue specifically in Group Replication is to issue a `STOP GROUP_REPLICATION` statement and then a `START GROUP_REPLICATION` statement to restart the instance. The Group Replication plugin creates the `group_replication_applier` channel again.

## Why does Group Replication use two bind addresses?

Group Replication uses two bind addresses in order to split network traffic between the SQL address, used by clients to communicate with the member, and the `group_replication_local_address`, used internally by the group members to communicate. For example, assume a server with two network interfaces assigned to the network addresses `203.0.113.1` and `198.51.100.179`. In such a situation you could use `203.0.113.1:33061` for the internal group network address by setting `group_replication_local_address=203.0.113.1:33061`. Then you could use `198.51.100.179` for `hostname` and `3306` for the `port`. Client SQL applications would then connect to the member at `198.51.100.179:3306`. This enables you to configure different rules on the different networks. Similarly, the internal group communication can be separated from the network connection used for client applications, for increased security.

## How does Group Replication use network addresses and hostnames?

Group Replication uses network connections between members and therefore its functionality is directly impacted by how you configure hostnames and ports. For example, the Group Replication recovery procedure is based on asynchronous replication which uses the server's hostname and port. When a member joins a group it receives the group membership information, using the network address information that is listed at `performance_schema.replication_group_members`. One of

the members listed in that table is selected as the donor of the missing data from the group to the new member.

This means that any value you configure using a hostname, such as the SQL network address or the group seeds address, must be a fully qualified name and resolvable by each member of the group. You can ensure this for example through DNS, or correctly configured `/etc/hosts` files, or other local processes. If you want to configure the `MEMBER_HOST` value on a server, specify it using the `--report-host` option on the server before joining it to the group.

#### Important

The assigned value is used directly and is not affected by the `skip_name_resolve` system variable.

To configure `MEMBER_PORT` on a server, specify it using the `report_port` system variable.

## Why did the auto increment setting on the server change?

When Group Replication is started on a server, the value of `auto_increment_increment` is changed to the value of `group_replication_auto_increment_increment`, which defaults to 7, and the value of `auto_increment_offset` is changed to the server ID. The changes are reverted when Group Replication is stopped. These settings avoid the selection of duplicate auto-increment values for writes on group members, which causes rollback of transactions. The default auto increment value of 7 for Group Replication represents a balance between the number of usable values and the permitted maximum size of a replication group (9 members).

The changes are only made and reverted if `auto_increment_increment` and `auto_increment_offset` each have their default value of 1. If their values have already been modified from the default, Group Replication does not alter them.

## How do I find the primary?

If the group is operating in single-primary mode, it can be useful to find out which member is the primary. See [Section 17.5.1.3, “Finding the Primary”](#)

## 17.9 Group Replication Technical Details

This section provides more technical details about MySQL Group Replication.

### 17.9.1 Group Replication Plugin Architecture

MySQL Group Replication is a MySQL plugin and it builds on the existing MySQL replication infrastructure, taking advantage of features such as the binary log, row-based logging, and global transaction identifiers. It integrates with current MySQL frameworks, such as the performance schema or plugin and service infrastructures. The following figure presents a block diagram depicting the overall architecture of MySQL Group Replication.

**Figure 17.9 Group Replication Plugin Block Diagram**

The MySQL Group Replication plugin includes a set of APIs for capture, apply, and lifecycle, which control how the plugin interacts with MySQL Server. There are interfaces to make information flow from the server to the plugin and vice versa. These interfaces isolate the MySQL Server core from the Group Replication plugin, and are mostly hooks placed in the transaction execution pipeline. In one direction, from server to the plugin, there are notifications for events such as the server starting, the server recovering, the server being ready to accept connections, and the server being about to commit a transaction. In the other direction, the plugin instructs the server to perform actions such as committing or aborting ongoing transactions, or queuing transactions in the relay log.

The next layer of the Group Replication plugin architecture is a set of components that react when a notification is routed to them. The capture component is responsible for keeping track of context related to transactions that are executing. The applier component is responsible for executing remote transactions on the database. The recovery component manages distributed recovery, and is responsible for getting a server that is joining the group up to date by selecting the donor, orchestrating the catch up procedure and reacting to donor failures.

Continuing down the stack, the replication protocol module contains the specific logic of the replication protocol. It handles conflict detection, and receives and propagates transactions to the group.

The final two layers of the Group Replication plugin architecture are the Group Communication System (GCS) API, and an implementation of a Paxos-based group communication engine (XCom). The GCS API is a high level API that abstracts the properties required to build a replicated state machine (see [Section 17.1, “Group Replication Background”](#)). It therefore decouples the implementation of the messaging layer from the remaining upper layers of the plugin. The group communication engine handles communications with the members of the replication group.

## 17.9.2 The Group

In MySQL Group Replication, a set of servers forms a replication group. A group has a name, which takes the form of a UUID. The group is dynamic and servers can leave (either voluntarily or involuntarily) and join it at any time. The group adjusts itself whenever servers join or leave.

If a server joins the group, it automatically brings itself up to date by fetching the missing state from an existing server. This state is transferred by means of Asynchronous MySQL replication. If a server leaves the group, for instance it was taken down for maintenance, the remaining servers notice that it has left and reconfigure the group automatically. The group membership service described at [Section 17.1.3.1, “Group Membership”](#) powers all of this.

## 17.9.3 Data Manipulation Statements

As there are no primary servers (sources) for any particular data set, every server in the group is allowed to execute transactions at any time, even transactions that change state (RW transactions).

Any server may execute a transaction without any *a priori* coordination. But, at commit time, it coordinates with the rest of the servers in the group to reach a decision on the fate of that transaction. This coordination serves two purposes: (i) check whether the transaction should commit or not; (ii) and propagate the changes so that other servers can apply the transaction as well.

As a transaction is sent through an atomic broadcast, either all servers in the group receive the transaction or none do. If they receive it, then they all receive it in the same order with respect to other transactions that were sent before. Conflict detection is carried out by inspecting and comparing write sets of transactions. Thus, they are detected at the row level. Conflict resolution follows the first committer wins rule. If t1 and t2 execute concurrently at different sites, because t2 is ordered before t1, and both changed the same row, then t2 wins the conflict and t1 aborts. In other words, t1 was trying to change data that had been rendered stale by t2.

### Note

If two transactions are bound to conflict more often than not, then it is a good practice to start them on the same server. They then have a chance to synchronize on the local lock manager instead of aborting later in the replication protocol.

## 17.9.4 Data Definition Statements

In a Group Replication topology, care needs to be taken when executing data definition statements also commonly known as data definition language (DDL). Given that MySQL does not support atomic or transactional DDL, one cannot optimistically execute DDL statements and later roll back if needs be. Consequently, the lack of atomicity does not fit directly into the optimistic replication paradigm that Group Replication is based on.

Therefore, more care needs to be taken when replicating data definition statements. Schema changes and changes to the data that the object contains need to be handled through the same server while the schema operation has not yet completed and replicated everywhere. Failure to do so can result in data inconsistency.

### Note

If the group is deployed in single-primary mode, then this is not a problem, because all changes are performed through the same server, the primary.

**Warning**

MySQL DDL execution is not atomic or transactional. The server executes and commits without securing group agreement first. As such, you must route DDL and DML for the same object through the same server, while the DDL is executing and has not replicated everywhere yet.

## 17.9.5 Distributed Recovery

This section describes the process through which a member joining a group catches up with the remaining servers in the group, called distributed recovery. Distributed recovery can be summarized as the process through which a server gets missing transactions from the group so that it can then join the group having processed the same set of transactions as the other group members.

### 17.9.5.1 Distributed Recovery Basics

Whenever a member joins a replication group, it connects to an existing member to carry out state transfer. The server joining the group transfers all the transactions that took place in the group before it joined, which are provided by the existing member (called the *donor*). Next, the server joining the group applies the transactions that took place in the group while this state transfer was in progress. When the server joining the group has caught up with the remaining servers in the group, it begins to participate normally in the group. This process is called distributed recovery.

#### Phase 1

In the first phase, the server joining the group selects one of the online servers on the group to be the *donor* of the state that it is missing. The donor is responsible for providing the server joining the group all the data it is missing up to the moment it has joined the group. This is achieved by relying on a standard asynchronous replication channel, established between the donor and the server joining the group, see [Section 16.2.2, “Replication Channels”](#). Through this replication channel, the donor's binary logs are replicated until the point that the view change happened when the server joining the group became part of the group. The server joining the group applies the donor's binary logs as it receives them.

While the binary log is being replicated, the server joining the group also caches every transaction that is exchanged within the group. In other words it is listening for transactions that are happening after it joined the group and while it is applying the missing state from the donor. When the first phase ends and the replication channel to the donor is closed, the server joining the group then starts phase two: the catch up.

#### Phase 2

In this phase, the server joining the group proceeds to the execution of the cached transactions. When the number of transactions queued for execution finally reaches zero, the member is declared online.

#### Resilience

The recovery procedure withstands donor failures while the server joining the group is fetching binary logs from it. In such cases, whenever a donor fails during phase 1, the server joining the group fails over to a new donor and resumes from that one. When that happens the server joining the group closes the connection to the failed server joining the group explicitly and opens a connection to a new donor. This happens automatically.

### 17.9.5.2 Recovering From a Point-in-time

To synchronize the server joining the group with the donor up to a specific point in time, the server joining the group and donor make use of the MySQL Global Transaction Identifiers (GTIDs) mechanism. See [Section 16.1.3, “Replication with Global Transaction Identifiers”](#). However, GTIDS

only provide a means to realize which transactions the server joining the group is missing, they do not help marking a specific point in time to which the server joining the group must catch up, nor do they help conveying certification information. This is the job of binary log view markers, which mark view changes in the binary log stream, and also contain additional metadata information, provisioning the server joining the group with missing certification related data.

## View and View Changes

To explain the concept of view change markers, it is important to understand what a view and a view change are.

A *view* corresponds to a group of members participating actively in the current configuration, in other words at a specific point in time. They are correct and online in the system.

A *view change* occurs when a modification to the group configuration happens, such as a member joining or leaving. Any group membership change results in an independent view change communicated to all members at the same logical point in time.

A *view identifier* uniquely identifies a view. It is generated whenever a view change happens

At the group communication layer, view changes with their associated view ids are then boundaries between the data exchanged before and after a member joins. This concept is implemented through a new binary log event: the "view change log event". The view id thus becomes a marker as well for transactions transmitted before and after changes happen in the group membership.

The view identifier itself is built from two parts: (i) one that is randomly generated and (ii) a monotonically increasing integer. The first part is generated when the group is created, and remains unchanged while there is at least one member in the group. The second part is incremented every time a view change happens.

The reason for this heterogeneous pair that makes up the view id is the need to unambiguously mark group changes whenever a member joins or leaves but also whenever all members leave the group and no information remains of what view the group was in. In fact, the sole use of monotonic increasing identifiers could lead to the reuse of the same id after full group shutdowns, destroying the uniqueness of the binary log data markers that recovery depends on. To summarize, the first part identifies whenever the group was started from the beginning and the incremental part when the group changed from that point on.

### 17.9.5.3 View Changes

This section explains the process which controls how the view change identifier is incorporated into a binary log event and written to the log. The following steps are taken:

#### Begin: Stable Group

All servers are online and processing incoming transactions from the group. Some servers may be a little behind in terms of transactions replicated, but eventually they converge. The group acts as one distributed and replicated database.

**Figure 17.10 Stable Group**

### **View Change: a Member Joins**

Whenever a new member joins the group and therefore a view change is performed, every online server queues a view change log event for execution. This is queued because before the view change, several transactions can be queued on the server to be applied and as such, these belong to the old view. Queuing the view change event after them guarantees a correct marking of when this happened.

Meanwhile, the server joining the group selects the donor from the list of online servers as stated by the membership service through the view abstraction. A member joins on view 4 and the online members write a View change event to the binary log.

**Figure 17.11 A Member Joins**

### State Transfer: Catching Up

Once the server joining the group has chosen which server in the group is to be the donor, a new asynchronous replication connection is established between the two and the state transfer begins (phase 1). This interaction with the donor continues until the server joining the group's applier thread processes the view change log event that corresponds to the view change triggered when the server joining the group came into the group. In other words, the server joining the group replicates from the donor, until it gets to the marker with the view identifier which matches the view marker it is already in.

**Figure 17.12 State Transfer: Catching Up**

As view identifiers are transmitted to all members in the group at the same logical time, the server joining the group knows at which view identifier it should stop replicating. This avoids complex GTID set calculations because the view id clearly marks which data belongs to each group view.

While the server joining the group is replicating from the donor, it is also caching incoming transactions from the group. Eventually, it stops replicating from the donor and switches to applying those that are cached.

**Figure 17.13 Queued Transactions**

### Finish: Caught Up

When the server joining the group recognizes a view change log event with the expected view identifier, the connection to the donor is terminated and it starts applying the cached transactions. An important point to understand is the final recovery procedure. Although it acts as a marker in the binary log, delimiting view changes, the view change log event also plays another role. It conveys the certification information as perceived by all servers when the server joining the group entered the group, in other words the last view change. Without it, the server joining the group would not have the necessary information to be able to certify (detect conflicts) subsequent transactions.

The duration of the catch up (phase 2) is not deterministic, because it depends on the workload and the rate of incoming transactions to the group. This process is completely online and the server joining the group does not block any other server in the group while it is catching up. Therefore the number of transactions the server joining the group is behind when it moves to phase 2 can, for this reason, vary and thus increase or decrease according to the workload.

When the server joining the group reaches zero queued transactions and its stored data is equal to the other members, its public state changes to online.

**Figure 17.14 Instance Online**

#### 17.9.5.4 Usage Advice and Limitations of Distributed Recovery

Distributed recovery does have some limitations. It is based on classic asynchronous replication and as such it may be slow if the server joining the group is not provisioned at all or is provisioned with a very old backup image. This means that if the data to transfer is too big at phase 1, the server may take a very long time to recover. As such, the recommendation is that before adding a server to the group, one should provision it with a fairly recent snapshot of a server already in the group. This minimizes the length of phase 1 and reduces the impact on the donor server, since it has to save and transfer less binary logs.

##### Warning

It is recommended that a server is provisioned before it is added to a group. That way, one minimizes the time spent on the recovery step.

#### 17.9.6 Observability

There is a lot of automation built into the Group Replication plugin. Nonetheless, you might sometimes need to understand what is happening behind the scenes. This is where the instrumentation of Group Replication and Performance Schema becomes important. The entire state of the system (including the view, conflict statistics and service states) can be queried through performance\_schema tables. The distributed nature of the replication protocol and the fact that server instances agree and thus synchronize on transactions and metadata makes it simpler to inspect the state of the group. For

example, you can connect to a single server in the group and obtain both local and global information by issuing select statements on the Group Replication related Performance Schema tables. For more information, see [Section 17.4, “Monitoring Group Replication”](#).

## 17.9.7 Group Replication Performance

This section explains how to use the available configuration options to gain the best performance from your group.

### 17.9.7.1 Fine Tuning the Group Communication Thread

The group communication thread (GCT) runs in a loop while the Group Replication plugin is loaded. The GCT receives messages from the group and from the plugin, handles quorum and failure detection related tasks, sends out some keep alive messages and also handles the incoming and outgoing transactions from/to the server/group. The GCT waits for incoming messages in a queue. When there are no messages, the GCT waits. By configuring this wait to be a little longer (doing an active wait) before actually going to sleep can prove to be beneficial in some cases. This is because the alternative is for the operating system to switch out the GCT from the processor and do a context switch.

To force the GCT do an active wait, use the `group_replication_poll_spin_loops` option, which makes the GCT loop, doing nothing relevant for the configured number of loops, before actually polling the queue for the next message.

For example:

```
mysql> SET GLOBAL group_replication_poll_spin_loops= 10000;
```

### 17.9.7.2 Message Compression

For messages sent between online group members, Group Replication enables message compression by default. Whether a specific message is compressed depends on the threshold that you configure using the `group_replication_compression_threshold` system variable. Messages that have a payload larger than the specified number of bytes are compressed.

The default compression threshold is 1000000 bytes. You could use the following statements to increase the compression threshold to 2MB, for example:

```
STOP GROUP_REPLICATION;
SET GLOBAL group_replication_compression_threshold = 2097152;
START GROUP_REPLICATION;
```

If you set `group_replication_compression_threshold` to zero, message compression is disabled.

Group Replication uses the LZ4 compression algorithm to compress messages sent in the group. Note that the maximum supported input size for the LZ4 compression algorithm is 2113929216 bytes. This limit is lower than the maximum possible value for the `group_replication_compression_threshold` system variable, which is matched to the maximum message size accepted by XCom. The LZ4 maximum input size is therefore a practical limit for message compression, and transactions above this size cannot be committed when message compression is enabled. With the LZ4 compression algorithm, do not set a value greater than 2113929216 bytes for `group_replication_compression_threshold`.

The value of `group_replication_compression_threshold` is not required by Group Replication to be the same on all group members. However, it is advisable to set the same value on all group members in order to avoid unnecessary rollback of transactions, failure of message delivery, or failure of message recovery.

Compression for messages sent in the group happens at the group communication engine level, before the data is handed over to the group communication thread, so it takes place within the context of the `mysql` user session thread. If the message payload size exceeds the threshold set by

`group_replication_compression_threshold`, the transaction payload is compressed before being sent out to the group, and decompressed when it is received. Upon receiving a message, the member checks the message envelope to verify whether it is compressed or not. If needed, then the member decompresses the transaction, before delivering it to the upper layer. This process is shown in the following figure.

Figure 17.15 Compression Support

When network bandwidth is a bottleneck, message compression can provide up to 30-40% throughput improvement at the group communication level. This is especially important within the context of large groups of servers under load. The TCP peer-to-peer nature of the interconnections between  $N$  participants in the group makes the sender send the same amount of data  $N$  times. Furthermore, binary logs are likely to exhibit a high compression ratio. This makes compression a compelling feature for Group Replication workloads that contain large transactions.

### 17.9.7.3 Flow Control

Group Replication ensures that a transaction only commits after a majority of the members in a group have received it and agreed on the relative order between all transactions that were sent concurrently.

This approach works well if the total number of writes to the group does not exceed the write capacity of any member in the group. If it does and some of the members have less write throughput than others, particularly less than the writer members, those members can start lagging behind of the writers.

Having some members lagging behind the group brings some problematic consequences, particularly, the reads on such members may externalize very old data. Depending on why the member is lagging behind, other members in the group may have to save more or less replication context to be able to fulfil potential data transfer requests from the slow member.

There is however a mechanism in the replication protocol to avoid having too much distance, in terms of transactions applied, between fast and slow members. This is known as the flow control mechanism. It tries to address several goals:

1. to keep the members close enough to make buffering and de-synchronization between members a small problem;
2. to adapt quickly to changing conditions like different workloads or more writers in the group;
3. to give each member a fair share of the available write capacity;
4. to not reduce throughput more than strictly necessary to avoid wasting resources.

Given the design of Group Replication, the decision whether to throttle or not may be decided taking into account two work queues: *(i)* the *certification* queue; *(ii)* and on the binary log *applier* queue. Whenever the size of one of these queues exceeds the user-defined threshold, the throttling mechanism is triggered. Only configure: *(i)* whether to do flow control at the certifier or at the applier level, or both; and *(ii)* what is the threshold for each queue.

The flow control depends on two basic mechanisms:

1. the monitoring of members to collect some statistics on throughput and queue sizes of all group members to make educated guesses on what is the maximum write pressure each member should be subjected to;
2. the throttling of members that are trying to write beyond their fair-share of the available capacity at each moment in time.

### Probes and Statistics

The monitoring mechanism works by having each member deploying a set of probes to collect information about its work queues and throughput. It then propagates that information to the group periodically to share that data with the other members.

Such probes are scattered throughout the plugin stack and allow one to establish metrics, such as:

- the certifier queue size;
- the replication applier queue size;
- the total number of transactions certified;
- the total number of remote transactions applied in the member;
- the total number of local transactions.

Once a member receives a message with statistics from another member, it calculates additional metrics regarding how many transactions were certified, applied and locally executed in the last monitoring period.

Monitoring data is shared with others in the group periodically. The monitoring period must be high enough to allow the other members to decide on the current write requests, but low enough that it

has minimal impact on group bandwidth. The information is shared every second, and this period is sufficient to address both concerns.

## Group Replication Throttling

Based on the metrics gathered across all servers in the group, a throttling mechanism kicks in and decides whether to limit the rate a member is able to execute/commit new transactions.

Therefore, metrics acquired from all members are the basis for calculating the capacity of each member: if a member has a large queue (for certification or the applier thread), then the capacity to execute new transactions should be close to ones certified or applied in the last period.

The lowest capacity of all the members in the group determines the real capacity of the group, while the number of local transactions determines how many members are writing to it, and, consequently, how many members should share that available capacity.

This means that every member has an established write quota based on the available capacity, in other words a number of transactions it can safely issue for the next period. The writer quota is enforced by the throttling mechanism if the queue size of the certifier or the binary log applier exceeds a user defined threshold.

The quota is reduced by the number of transactions that were delayed in the last period, and then also further reduced by 10% to allow the queue that triggered the problem to reduce its size. In order to avoid large jumps in throughput once the queue size goes beyond the threshold, the throughput is only allowed to grow by the same 10% per period after that.

The current throttling mechanism does not penalize transactions below quota, but delays finishing those transactions that exceed it until the end of the monitoring period. As a consequence, if the quota is very small for the write requests issued some transactions may have latencies close to the monitoring period.

---

## Chapter 18 MySQL Shell

MySQL Shell is an advanced client and code editor for MySQL Server. In addition to the provided SQL functionality, similar to [mysql](#), MySQL Shell provides scripting capabilities for JavaScript and Python and includes APIs for working with MySQL. MySQL Shell is a component that you can install separately.

The following discussion briefly describes MySQL Shell's capabilities. For more information, see the MySQL Shell manual, available at <https://dev.mysql.com/doc/mysql-shell/en/>.

MySQL Shell includes the following APIs implemented in JavaScript and Python which you can use to develop code that interacts with MySQL.

- The X DevAPI enables developers to work with both relational and document data when MySQL Shell is connected to a MySQL server using the X Protocol. This enables you to use MySQL as a Document Store, sometimes referred to as “using NoSQL”. For more information, see [Chapter 19, Using MySQL as a Document Store](#). For documentation on the concepts and usage of X DevAPI, which is implemented in MySQL Shell, see [X DevAPI User Guide](#).
- The AdminAPI enables database administrators to work with InnoDB Cluster, which provides an integrated solution for high availability and scalability using InnoDB based MySQL databases, without requiring advanced MySQL expertise. The AdminAPI also includes support for InnoDB ReplicaSet, which enables you to administer a set of MySQL instances running asynchronous GTID-based replication in a similar way to InnoDB Cluster. Additionally, the AdminAPI makes administration of MySQL Router easier, including integration with both InnoDB Cluster and InnoDB ReplicaSet. See [Using MySQL AdminAPI](#).

MySQL Shell is available in two editions, the Community Edition and the Commercial Edition. The Community Edition is available free of charge. The Commercial Edition provides additional Enterprise features at low cost.

---

# Chapter 19 Using MySQL as a Document Store

## Table of Contents

This chapter introduces an alternative way of working with MySQL as a document store, sometimes referred to as “using NoSQL”. If your intention is to use MySQL in a traditional (SQL) way, this chapter is probably not relevant to you.

### Important

MySQL Shell 8.0 is the most recent version and is highly recommended for use with MySQL Server 5.7. Please upgrade to MySQL Shell 8.0. If you have not yet installed MySQL Shell, download it from the [download site](#). See the [MySQL Shell 8.0](#) documentation for the latest documentation. This chapter covers configuring MySQL 5.7 server as a document store and is compatible with version 8.0 clients such as MySQL Shell and MySQL Connectors.

Relational databases such as MySQL usually required a document schema to be defined before documents can be stored. The features described in this section enable you to use MySQL as a document store, which is a schema-less, and therefore schema-flexible, storage system for documents. When using MySQL as a document store, to create documents describing products you do not need to know and define all possible attributes of any products before storing them and operating with them. This differs from working with a relational database and storing products in a table, when all columns of the table must be known and defined before adding any products to the database. The features described in this chapter enable you to choose how you configure MySQL, using only the document store model, or combining the flexibility of the document store model with the power of the relational model.

These sections cover the usage of MySQL as a document store:

- The [Section 19.1, “Key Concepts”](#) section covers concepts like Document, Collection, Session, and Schema to help you understand how to use MySQL as a document store.
- The [Section 19.2, “Setting Up MySQL as a Document Store”](#) section explains how to configure X Plugin on a MySQL Server, so it can function as a document store, and how to install MySQL Shell to use as a client.
- [MySQL Shell 8.0](#) provides more detailed information about using MySQL Shell.
- [X DevAPI User guide](#).

Clients that communicate with a MySQL Server using the X Protocol can use the X DevAPI to develop applications. For example MySQL Shell and MySQL Connectors provide this ability by implementing the X DevAPI. X DevAPI offers a modern programming interface with a simple yet powerful design which provides support for established industry standard concepts. See [X DevAPI User Guide](#) for in-depth tutorials on using X DevAPI.

- The following MySQL products support the X Protocol and enable you to use X DevAPI in your chosen language to develop applications that communicate with a MySQL Server functioning as a document store.
    - MySQL Shell provides implementations of X DevAPI in JavaScript and Python.
    - Connector/C++
    - Connector/J
    - Connector/Node.js
    - Connector/.NET
    - Connector/Python

## 19.1 Key Concepts

This section explains the concepts introduced as part of using MySQL as a document store.

## Document

A Document is a set of key and value pairs, as represented by a JSON object. A Document is represented internally using the MySQL binary JSON object, through the JSON MySQL datatype. The values of fields can contain other documents, arrays, and lists of documents.

```
{
 "GNP": 4834,
 "_id": "00005de917d800000000000000000023",
 "Code": "BWA",
 "Name": "Botswana",
 "IndepYear": 1966,
 "geography": {
 "Region": "Southern Africa",
 "Continent": "Africa",
 "SurfaceArea": 581730
 },
 "government": {
 "HeadOfState": "Festus G. Mogae",
 "GovernmentForm": "Republic"
 },
 "demographics": {
 "Population": 1622000,
 "LifeExpectancy": 39.29999923706055
 }
}
```

## Collection

A Collection is a container that may be used to store Documents in a MySQL database.

# CRUD Operations

Create, Read, Update and Delete (CRUD) operations are the four basic operations that can be performed on a database Collection or Table. In terms of MySQL this means:

- Create a new entry (insertion or addition)
  - Read entries (queries)
  - Update entries
  - Delete entries

## X Plugin

The MySQL Server plugin which enables communication using X Protocol. Supports clients that implement X DevAPI and enables you to use MySQL as a document store.

## X Protocol

A protocol to communicate with a MySQL Server running X Plugin. X Protocol supports both CRUD and SQL operations, authentication via SASL, allows streaming (pipelining) of commands and is extensible on the protocol and the message layer.

## 19.2 Setting Up MySQL as a Document Store

To use MySQL 5.7 as a document store, the X Plugin needs to be installed. Then you can use X Protocol to communicate with the server. Without the X Plugin running, X Protocol clients cannot connect to the server. The X Plugin is supplied with MySQL (5.7.12 or higher) — installing it does not involve a separate download. This section describes how to install X Plugin.

Follow the steps outlined here:

**1. Install or upgrade to MySQL 5.7.12 or higher.**

When the [installation](#) or upgrade is done, start the server. For server startup instructions, see [Section 2.10.2, “Starting the Server”](#).

**Note**

MySQL Installer enables you to perform this and the next step (Install the X Plugin) at the same time for new installations on Microsoft Windows. In the **Plugin and Extensions** screen, check mark the **Enable X Protocol/MySQL as a Document Store** check box. After the installation, verify that the X Plugin has been installed.

**2. Install the X Plugin.** A non-root account can be used to install the plugin as long as the account has [INSERT](#) privilege for the `mysql.plugin` table.

Always save your existing configuration settings before reconfiguring the server.

To install the built-in X Plugin, do one of the following:

- Using [MySQL Installer for Windows](#):
  - a. Launch MySQL Installer for Windows. MySQL Installer dashboard opens.
  - b. Click the **Reconfigure** quick action for MySQL Server. Use **Next** and **Back** to configure the following items:
    - In **Accounts and Roles**, confirm the current `root` account password.
    - In **Plugin and Extensions**, check mark the **Enable X Protocol/MySQL as a Document Store** check box. MySQL Installer provides a default port number and opens the firewall port for network access.
    - In **Apply Server Configuration**, click **Execute**.
    - Click **Finish** to close MySQL Installer.
  - c. [Install MySQL Shell](#).
- Using MySQL Shell:

- a. [Install MySQL Shell](#).
- b. Open a terminal window (command prompt on Windows) and navigate to the MySQL binaries location (for example, `/usr/bin/` on Linux).
- c. Run the following command:

```
mysqlsh -u user -h localhost --classic --dba enableXProtocol
```

- Using the MySQL Client program:
  - a. Open a terminal window (command prompt on Windows) and navigate to the MySQL binaries location (for example, `/usr/bin/` on Linux).
  - b. Invoke the `mysql` command-line client:

```
mysql -u user -p
```

- c. Issue the following statement:

```
mysql> INSTALL PLUGIN mysqlx SONAME 'mysqlx.so';
```

Replace `mysqlx.so` with `mysqlx.dll` for Windows.

#### Important

The `mysql.session` user must exist before you can load X Plugin. `mysql.session` was added in MySQL version 5.7.19. If your data dictionary was initialized using an earlier version you must run the `mysql_upgrade` procedure. If the upgrade is not run, X Plugin fails to start with the error message `There was an error when trying to access the server with user: mysql.session@localhost`. Make sure the user is present in the server and that `mysql_upgrade` was ran after a server update..

- d. [Install MySQL Shell](#).
3. **Verify that the X Plugin has been installed.**

When the X Plugin is installed properly, it shows up in the list when you query for active plugins on the server with one of the following commands:

- MySQL Shell command:

```
mysqlsh -u user --sqlc -e "show plugins"
```

- MySQL Client program command:

```
mysql -u user -p -e "show plugins"
```

If you encounter problems with the X Plugin installation, or if you want to learn about alternative ways of installing, configuring, or uninstalling server plugins, see [Section 5.5.1, “Installing and Uninstalling Plugins”](#).

## `mysqlxsys@localhost` User Account

Installing the X Plugin creates a `mysqlxsys@localhost` user account. If, for some reason, creating the user account fails, the X Plugin installation fails, too. Here is an explanation on what the `mysqlxsys@localhost` user account is for and what to do when its creation fails.

The X Plugin installation process uses the MySQL `root` user to create an internal account for the `mysqlxsys@localhost` user. The `mysqlxsys@localhost` account is used by the X Plugin for authentication of external users against the MySQL account system and for killing sessions when requested by a privileged user. The `mysqlxsys@localhost` account is created as locked, so it cannot be used to log in by external users. If for some reason the MySQL `root` account is not available, before you start the X Plugin installation you must manually create the `mysqlxsys@localhost` user by issuing the following statements in the `mysql` command-line client:

```
CREATE USER IF NOT EXISTS mysqlxsys@localhost IDENTIFIED WITH
mysql_native_password AS 'password' ACCOUNT LOCK;
GRANT SELECT ON mysql.user TO mysqlxsys@localhost;
GRANT SUPER ON *.* TO mysqlxsys@localhost;
```

## Uninstalling the X Plugin

If you ever want to uninstall (deactivate) the X Plugin, issue the following statement in the `mysql` command-line client:

```
UNINSTALL PLUGIN mysqlx;
```

Do not use MySQL Shell to issue the previous statement. It works from MySQL Shell, but you get an error (code 1130). Also, uninstalling the plugin removes the `mysqlxsys` user.

### 19.2.1 Installing MySQL Shell

This section describes how to download, install, and start MySQL Shell, which is an interactive JavaScript, Python, or SQL interface supporting development and administration for the MySQL Server. MySQL Shell is a component that you can install separately.

#### Requirements

MySQL Shell is available on Microsoft Windows, Linux, and macOS for 64-bit platforms. MySQL Shell requires that the built-in X Plugin be active. You can install the server plugin before or after you install MySQL Shell. For instructions, see [Installing the X Plugin](#).

##### 19.2.1.1 Installing MySQL Shell on Microsoft Windows

###### Important

The Community version of MySQL Shell requires the Visual C++ Redistributable for Visual Studio 2013 (available at the [Microsoft Download Center](#)) to work; make sure that is installed on your Windows system before installing MySQL Shell.

###### Note

MySQL Shell is currently not supplied with an MSI Installer. See [Installing MySQL Shell Binaries](#) for the manual install procedure.

To install MySQL Shell on Microsoft Windows using the MSI Installer, do the following:

1. Download the **Windows (x86, 64-bit), MSI Installer** package from <http://dev.mysql.com/downloads/shell/>.
2. When prompted, click **Run**.
3. Follow the steps in the Setup Wizard.

**Figure 19.1 Installation of MySQL Shell on Windows**

If you have installed MySQL without enabling the X Plugin, then later on decide you want to install the X Plugin, or if you are installing MySQL *without* using MySQL Installer, see [Installing the X Plugin](#).

## Installing MySQL Shell Binaries

To install MySQL Shell binaries:

1. Unzip the content of the Zip file to the MySQL products directory, for example `C:\Program Files\MySQL\`.
2. To be able to start MySQL Shell from a command prompt add the bin directory `C:\Program Files\MySQL\mysql-shell-1.0.8-rc-windows-x86-64bit\bin` to the `PATH` system variable.

### 19.2.1.2 Installing MySQL Shell on Linux

#### Note

Installation packages for MySQL Shell are available only for a limited number of Linux distributions, and only for 64-bit systems.

For supported Linux distributions, the easiest way to install MySQL Shell on Linux is to use the [MySQL APT repository](#) or [MySQL Yum repository](#). For systems not using the MySQL repositories, MySQL Shell can also be downloaded and installed directly.

## Installing MySQL Shell with the MySQL APT Repository

For Linux distributions supported by the [MySQL APT repository](#), follow one of the paths below:

- If you do not yet have the [MySQL APT repository](#) as a software repository on your system, do the following:
  - Follow the steps given in [Adding the MySQL APT Repository](#), paying special attention to the following:
    - During the installation of the configuration package, when asked in the dialogue box to configure the repository, make sure you choose MySQL 5.7 (which is the default option) as the release series you want, and enable the **MySQL Preview Packages** component.

- Make sure you do not skip the step for updating package information for the MySQL APT repository:

```
sudo apt-get update
```

- Install MySQL Shell with this command:

```
sudo apt-get install mysql-shell
```

- If you already have the [MySQL APT repository](#) as a software repository on your system, do the following:

- Update package information for the MySQL APT repository:

```
sudo apt-get update
```

- Update the MySQL APT repository configuration package with the following command:

```
sudo apt-get install mysql-apt-config
```

When asked in the dialogue box to configure the repository, make sure you choose MySQL 5.7 (which is the default option) as the release series you want, and enable the **MySQL Preview Packages** component.

- Install MySQL Shell with this command:

```
sudo apt-get install mysql-shell
```

## Installing MySQL Shell with the MySQL Yum Repository

For Linux distributions supported by the [MySQL Yum repository](#), follow these steps to install MySQL Shell:

- Do one of the following:

- If you already have the [MySQL Yum repository](#) as a software repository on your system and the repository was configured with the new release package `mysql57-community-release`, skip to the next step ("Enable the MySQL Tools Preview subrepository...").
  - If you already have the [MySQL Yum repository](#) as a software repository on your system but have configured the repository with the old release package `mysql-community-release`, it is easiest to install MySQL Shell by first reconfiguring the MySQL Yum repository with the new `mysql57-community-release` package. To do so, you need to remove your old release package first, with the following command :

```
sudo yum remove mysql-community-release
```

For dnf-enabled systems, do this instead:

```
sudo dnf erase mysql-community-release
```

Then, follow the steps given in [Adding the MySQL Yum Repository](#) to install the new release package, `mysql57-community-release`.

- If you do not yet have the [MySQL Yum repository](#) as a software repository on your system, follow the steps given in [Adding the MySQL Yum Repository](#).
- Enable the MySQL Tools Preview subrepository. You can do that by editing manually the `/etc/yum.repos.d/mysql-community.repo` file. This is an example of the subrepository's default entry in the file (the `baseurl` entry in your file might look different, depending on your Linux distribution):

```
[mysql-tools-preview]
```

```
name=MySQL Tools Preview
baseurl=http://repo.mysql.com/yum/mysql-tools-preview/el/6/$basearch/
enabled=0
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql
```

Change the entry `enabled=0` to `enabled=1` to enable the subrepository.

- Install MySQL Shell with this command:

```
sudo yum install mysql-shell
```

For dnf-enabled systems, do this instead:

```
sudo dnf install mysql-shell
```

## Installing MySQL Shell from Direct Downloads from the MySQL Developer Zone

RPM, Debian, and source packages for installing MySQL Shell are also available for download at [Download MySQL Shell](#).

### 19.2.1.3 Installing MySQL Shell on macOS

To install MySQL Shell on macOS, do the following:

1. Download the package from <http://dev.mysql.com/downloads/shell/>.
2. Double-click the downloaded DMG to mount it. Finder opens.
3. Double-click the `.pkg` file shown in the Finder window.
4. Follow the steps in the installation wizard.

**Figure 19.2 Installation of MySQL Shell on macOS**

5. When the installer finishes, eject the DMG. (It can be deleted.)

### 19.2.2 Starting MySQL Shell

You need an account name and password to establish a session using MySQL Shell. Replace `user` with your account name.

On the same system where the server instance is running, open a terminal window (command prompt on Windows) and start MySQL Shell with the following command:

```
mysqlsh --uri user@localhost
```

You are prompted to input your password and then this establishes an X Session.

For instructions to get you started using MySQL as a document store, see the following quick-start guides:

- [Quick-Start Guide: MySQL Shell for JavaScript](#)
- [Quick-Start Guide: MySQL Shell for Python](#)

## 19.3 Quick-Start Guide: MySQL for Visual Studio

This section explains how to use MySQL Shell to script a server using MySQL for Visual Studio.

### Introduction

MySQL for Visual Studio provides access to MySQL objects and data without forcing developers to leave Visual Studio. Designed and developed as a Visual Studio package, MySQL for Visual Studio integrates directly into Server Explorer providing a seamless experience for setting up new connections and working with database objects.

The following MySQL for Visual Studio features are available as of version 2.0.2:

- JavaScript and Python code editors, where scripts in those languages can be executed to query data from a MySQL database.
- Better integration with the Server Explorer to open MySQL, JavaScript, and Python code editors directly from a connected MySQL instance.
- A newer user interface for displaying query results, where different views are presented from result sets returned by a MySQL Server like:
  - Multiple tabs for each result set returned by an executed query.
  - Results view, where the information can be seen in grid, tree, or text representation for JSON results.
  - Field types view, where information about the columns of a result set is shown, such as names, data types, character sets, and more.
  - Query statistics view, displaying information about the executed query such as execution times, processed rows, index and temporary tables usage, and more.
  - Execution plan view, displaying an explanation of the query execution done internally by the MySQL Server.

### Getting Started

The requirements are MySQL for Visual Studio 2.0.2 or higher, and Visual Studio 2010 or higher. X DevAPI support requires MySQL Server 5.7.12 or higher with the X plugin enabled.

### Opening a Code Editor

Before opening a code editor that can execute queries against a MySQL server, a connection needs to be established:

1. Open the Server Explorer pane through the View menu, or with **Control + W, K**.
2. Right-click on the Data Connections node, select **Add Connection....**
3. In the **Add Connection** dialog, make sure the MySQL Data Provider is being used and fill in all the information.

**Note**

To enter the port number, click **Advanced...** and set the Port among the list of connection properties.

4. Click **Test Connection** to ensure you have a valid connection, then click **OK**.
5. Right-click your newly created connection, select **New MySQL Script** and then the language for the code editor you want to open.

For existing MySQL connections, to create a new editor you need only to do the last step.

## Using the Code Editor

The MySQL script editors have a toolbar at the start where information about the session is displayed, along with the actions that can be executed.

**Note**

Note the first two buttons in the toolbar represent a way to connect or disconnect from a MySQL server. If the editor was opened from the Server Explorer, the connection should be already established for the new editor window.

The third button is the **Run** button, the script contained in the editor window is executed by clicking it and results from the script execution are displayed below the script window.

**Note**

Some commands in the MySQL Shell can be executed without appending `execute()` while in interactive mode. In MySQL for Visual Studio, these commands do require `execute()`. In other words, append ".execute()" to execute commands.

## 19.4 X Plugin

This section explains how to configure and monitor the X Plugin.

### 19.4.1 Using Encrypted Connections with X Plugin

This section explains how to configure X Plugin to use encrypted connections. For more background information, see [Section 6.3, “Using Encrypted Connections”](#).

To enable configuring support for encrypted connections, X Plugin has `mysqlx_ssl_xxx` system variables, which can have different values from the `ssl_xxx` system variables used with MySQL Server. For example, X Plugin can have SSL key, certificate, and certificate authority files that differ from those used for MySQL Server. These variables are described at [Section 19.4.2.2, “X Plugin Options and System Variables”](#). Similarly, X Plugin has its own `Mysqlx_ssl_xxx` status variables that correspond to the MySQL Server encrypted-connection `Ssl_xxx` status variables. See [Section 19.4.2.3, “X Plugin Status Variables”](#).

At initialization, X Plugin determines its configuration for encrypted connections as follows:

- If all `mysqlx_ssl_xxx` system variables have their default values, X Plugin configures encrypted connections using the values of the MySQL Server `ssl_xxx` system variables.
- If any `mysqlx_ssl_xxx` variable has a nondefault value, X Plugin configures encrypted connections using the values of its own system variables. (This is the case if any `mysqlx_ssl_xxx` system variable is set to a value different from its default.)

This means that, on a server with X Plugin enabled, you can choose to have MySQL Protocol and X Protocol connections share the same encryption configuration by setting only the `ssl_xxx` variables,

or have separate encryption configurations for MySQL Protocol and X Protocol connections by configuring the `ssl_xxx` and `mysqlx_ssl_xxx` variables separately.

To have MySQL Protocol and X Protocol connections use the same encryption configuration, set only the `ssl_xxx` system variables in `my.cnf`:

```
[mysqld]
ssl_ca=ca.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
```

To configure encryption separately for MySQL Protocol and X Protocol connections, set both the `ssl_xxx` and `mysqlx_ssl_xxx` system variables in `my.cnf`:

```
[mysqld]
ssl_ca=ca1.pem
ssl_cert=server-cert1.pem
ssl_key=server-key1.pem

mysqlx_ssl_ca=ca2.pem
mysqlx_ssl_cert=server-cert2.pem
mysqlx_ssl_key=server-key2.pem
```

For general information about configuring connection-encryption support, see [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#). That discussion is written for MySQL Server, but the parameter names are similar for X Plugin. (The X Plugin `mysqlx_ssl_xxx` system variable names correspond to the MySQL Server `ssl_xxx` system variable names.)

The `tls_version` system variable that determines the permitted TLS versions for MySQL Protocol connections also applies to X Protocol connections. The permitted TLS versions for both types of connections are therefore the same.

Encryption per connection is optional, but a specific user can be required to use encryption for X Protocol and MySQL Protocol connections by including an appropriate `REQUIRE` clause in the `CREATE USER` statement that creates the user. For details, see [Section 13.7.1.2, “CREATE USER Statement”](#). Alternatively, to require all users to use encryption for X Protocol and MySQL Protocol connections, enable the `require_secure_transport` system variable. For additional information, see [Configuring Encrypted Connections as Mandatory](#).

## 19.4.2 X Plugin Options and Variables

This section describes the command options and system variables that configure X Plugin, as well as the status variables available for monitoring purposes. If configuration values specified at startup time are incorrect, X Plugin could fail to initialize properly and the server does not load it. In this case, the server could also produce error messages for other X Plugin settings because it cannot recognize them.

### 19.4.2.1 X Plugin Option and Variable Reference

This table provides an overview of the command options, system variables, and status variables provided by X Plugin.

**Table 19.1 X Plugin Option and Variable Reference**

| Name                                | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dy  |
|-------------------------------------|----------|-------------|------------|------------|-----------|-----|
| <code>mysqlx</code>                 | Yes      | Yes         |            |            |           |     |
| <code>Mysqlx_address</code>         |          |             |            | Yes        | Global    | No  |
| <code>mysqlx_bind_address</code>    | Yes      | Yes         | Yes        |            | Global    | No  |
| <code>Mysqlx_bytes_received</code>  |          |             |            | Yes        | Both      | No  |
| <code>Mysqlx_bytes_sent</code>      |          |             |            | Yes        | Both      | No  |
| <code>mysqlx_connect_timeout</code> | Yes      | Yes         | Yes        |            | Global    | Yes |

| Name                                    | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynam... |
|-----------------------------------------|----------|-------------|------------|------------|-----------|----------|
| Mysqlx_connection_accept_errors         |          |             |            | Yes        | Both      | No       |
| Mysqlx_connection_errors                |          |             |            | Yes        | Both      | No       |
| Mysqlx_connections_accepted             |          |             |            | Yes        | Global    | No       |
| Mysqlx_connections_closed               |          |             |            | Yes        | Global    | No       |
| Mysqlx_connections_rejected             |          |             |            | Yes        | Global    | No       |
| Mysqlx_crud_create_view                 |          |             |            | Yes        | Both      | No       |
| Mysqlx_crud_delete                      |          |             |            | Yes        | Both      | No       |
| Mysqlx_crud_drop_view                   |          |             |            | Yes        | Both      | No       |
| Mysqlx_crud_find                        |          |             |            | Yes        | Both      | No       |
| Mysqlx_crud_insert                      |          |             |            | Yes        | Both      | No       |
| Mysqlx_crud_modify_view                 |          |             |            | Yes        | Both      | No       |
| Mysqlx_crud_update                      |          |             |            | Yes        | Both      | No       |
| Mysqlx_errors_sent                      |          |             |            | Yes        | Both      | No       |
| Mysqlx_errors_unknown_message_type      |          |             |            | Yes        | Both      | No       |
| Mysqlx_expect_close                     |          |             |            | Yes        | Both      | No       |
| Mysqlx_expect_open                      |          |             |            | Yes        | Both      | No       |
| mysqlx_idle_worker_th...<br>Yes_timeout | Yes      | Yes         | Yes        |            | Global    | Yes      |
| Mysqlx_init_error                       |          |             |            | Yes        | Both      | No       |
| mysqlx_max_allowed...<br>Yesocket       | Yes      | Yes         | Yes        |            | Global    | Yes      |
| mysqlx_max_connections                  | Yes      | Yes         | Yes        |            | Global    | Yes      |
| mysqlx_min_worker_th...<br>Yes          | Yes      | Yes         | Yes        |            | Global    | Yes      |
| Mysqlx_notice_other_sent                |          |             |            | Yes        | Both      | No       |
| Mysqlx_notice_warning_sent              |          |             |            | Yes        | Both      | No       |
| Mysqlx_port                             |          |             |            | Yes        | Global    | No       |
| mysqlx_port                             | Yes      | Yes         | Yes        |            | Global    | No       |
| mysqlx_port_open_time                   | Yes      | Yes         | Yes        |            | Global    | No       |
| Mysqlx_rows_sent                        |          |             |            | Yes        | Both      | No       |
| Mysqlx_sessions                         |          |             |            | Yes        | Global    | No       |
| Mysqlx_sessions_accepted                |          |             |            | Yes        | Global    | No       |
| Mysqlx_sessions_closed                  |          |             |            | Yes        | Global    | No       |
| Mysqlx_sessions_fatal_error             |          |             |            | Yes        | Global    | No       |
| Mysqlx_sessions_killed                  |          |             |            | Yes        | Global    | No       |
| Mysqlx_sessions_rejected                |          |             |            | Yes        | Global    | No       |

| Mysqlx_ssl_accepts                      |          |             |            | Yes        | Global    | No       |
| Mysqlx_ssl_active                       |          |             |            | Yes        | Both      | No       |
| mysqlx_ssl_ca                           | Yes      | Yes         | Yes        |            | Global    | No       |
| mysqlx_ssl_capath                       | Yes      | Yes         | Yes        |            | Global    | No       |
| mysqlx_ssl_cert                         | Yes      | Yes         | Yes        |            | Global    | No       |

| Name                                | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dy |
|-------------------------------------|----------|-------------|------------|------------|-----------|----|
| Mysqlx_ssl_cipher                   |          |             |            | Yes        | Both      | No |
| mysqlx_ssl_cipher                   | Yes      | Yes         | Yes        |            | Global    | No |
| Mysqlx_ssl_cipher_list              |          |             |            | Yes        | Both      | No |
| mysqlx_ssl_crl                      | Yes      | Yes         | Yes        |            | Global    | No |
| mysqlx_ssl_crlpath                  | Yes      | Yes         | Yes        |            | Global    | No |
| Mysqlx_ssl_ctx_verify_depth         |          |             |            | Yes        | Both      | No |
| Mysqlx_ssl_ctx_verify_mode          |          |             |            | Yes        | Both      | No |
| Mysqlx_ssl_finished_accepts         |          |             |            | Yes        | Global    | No |
| mysqlx_ssl_key                      | Yes      | Yes         | Yes        |            | Global    | No |
| Mysqlx_ssl_server_not_after         |          |             |            | Yes        | Global    | No |
| Mysqlx_ssl_server_not_before        |          |             |            | Yes        | Global    | No |
| Mysqlx_ssl_verify_depth             |          |             |            | Yes        | Global    | No |
| Mysqlx_ssl_verify_mode              |          |             |            | Yes        | Global    | No |
| Mysqlx_ssl_version                  |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_create_collection       |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_create_collection_index |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_disable_notices         |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_drop_collection         |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_drop_collection_index   |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_enable_notices          |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_ensure_collection       |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_execute_mysqlx          |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_execute_sql             |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_execute_xplugin         |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_kill_client             |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_list_clients            |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_list_notices            |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_list_objects            |          |             |            | Yes        | Both      | No |
| Mysqlx_stmt_ping                    |          |             |            | Yes        | Both      | No |
| Mysqlx_worker_threads               |          |             |            | Yes        | Global    | No |
| Mysqlx_worker_threads_active        |          |             |            | Yes        | Global    | No |

#### 19.4.2.2 X Plugin Options and System Variables

To control activation of X Plugin, use this option:

- `--mysqlx[=value]`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--mysqlx[=value ]</code> |
| Introduced          | 5.7.12                         |
| Type                | Enumeration                    |
| Default Value       | ON                             |
| Valid Values        | ON                             |

|                      |
|----------------------|
| OFF                  |
| FORCE                |
| FORCE_PLUS_PERMANENT |

This option controls how the server loads X Plugin at startup. It is available only if the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load` or `--plugin-load-add`.

The option value should be one of those available for plugin-loading options, as described in [Section 5.5.1, “Installing and Uninstalling Plugins”](#). For example, `--mysqlx=FORCE_PLUS_PERMANENT` tells the server to load the plugin and prevent it from being removed while the server is running.

If X Plugin is enabled, it exposes several system variables that permit control over its operation:

- `mysqlx_bind_address`

| Command-Line Format | <code>--mysqlx-bind-address=addr</code> |
|---------------------|-----------------------------------------|
| Introduced          | 5.7.17                                  |
| System Variable     | <code>mysqlx_bind_address</code>        |
| Scope               | Global                                  |
| Dynamic             | No                                      |
| Type                | String                                  |
| Default Value       | *                                       |

The network address on which X Plugin listens for TCP/IP connections. This variable is not dynamic and can be configured only at startup. This is the X Plugin equivalent of the `bind_address` system variable; see that variable description for more information.

`mysqlx_bind_address` accepts a single address value, which may specify a single non-wildcard IP address or host name, or one of the wildcard address formats that permit listening on multiple network interfaces (\*, `0.0.0.0`, or `::`).

An IP address can be specified as an IPv4 or IPv6 address. If the value is a host name, X Plugin resolves the name to an IP address and binds to that address. If a host name resolves to multiple IP addresses, X Plugin uses the first IPv4 address if there are any, or the first IPv6 address otherwise.

X Plugin treats different types of addresses as follows:

- If the address is \*, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections for X Plugin. This value is the default.
- If the address is `0.0.0.0`, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces.
- If the address is `::`, X Plugin accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces.
- If the address is an IPv4-mapped address, X Plugin accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if X Plugin is bound to `::ffff:127.0.0.1`, a client such as MySQL Shell can connect using `--host=127.0.0.1` or `--host=:ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `::1`), X Plugin accepts TCP/IP connections only for that IPv4 or IPv6 address.

If binding to the address fails, X Plugin produces an error and the server does not load it.

- [mysqlx\\_connect\\_timeout](#)

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | --mysqlx-connect-timeout=#             |
| Introduced          | 5.7.12                                 |
| System Variable     | <a href="#">mysqlx_connect_timeout</a> |
| Scope               | Global                                 |
| Dynamic             | Yes                                    |
| Type                | Integer                                |
| Default Value       | 30                                     |
| Minimum Value       | 1                                      |
| Maximum Value       | 1000000000                             |

The number of seconds X Plugin waits for the first packet to be received from newly connected clients. This is the X Plugin equivalent of [connect\\_timeout](#); see that variable description for more information.

- [mysqlx\\_idle\\_worker\\_thread\\_timeout](#)

|                     |                                                   |
|---------------------|---------------------------------------------------|
| Command-Line Format | --mysqlx-idle-worker-thread-timeout=#             |
| Introduced          | 5.7.12                                            |
| System Variable     | <a href="#">mysqlx_idle_worker_thread_timeout</a> |
| Scope               | Global                                            |
| Dynamic             | Yes                                               |
| Type                | Integer                                           |
| Default Value       | 60                                                |
| Minimum Value       | 0                                                 |
| Maximum Value       | 3600                                              |

The number of seconds after which idle worker threads are terminated.

- [mysqlx\\_max\\_allowed\\_packet](#)

|                     |                                           |
|---------------------|-------------------------------------------|
| Command-Line Format | --mysqlx-max-allowed-packet=#             |
| Introduced          | 5.7.12                                    |
| System Variable     | <a href="#">mysqlx_max_allowed_packet</a> |
| Scope               | Global                                    |
| Dynamic             | Yes                                       |
| Type                | Integer                                   |
| Default Value       | 67108864                                  |
| Minimum Value       | 512                                       |
| Maximum Value       | 1073741824                                |

The maximum size of network packets that can be received by X Plugin. This is the X Plugin equivalent of [max\\_allowed\\_packet](#); see that variable description for more information.

- [mysqlx\\_max\\_connections](#)

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--mysqlx-max-connections=#</code> |
| Introduced          | 5.7.12                                  |
| System Variable     | <a href="#">mysqlx_max_connections</a>  |
| Scope               | Global                                  |
| Dynamic             | Yes                                     |
| Type                | Integer                                 |
| Default Value       | 100                                     |
| Minimum Value       | 1                                       |
| Maximum Value       | 65535                                   |

The maximum number of concurrent client connections X Plugin can accept. This is the X Plugin equivalent of [max\\_connections](#); see that variable description for more information.

For modifications to this variable, if the new value is smaller than the current number of connections, the new limit is taken into account only for new connections.

- [mysqlx\\_min\\_worker\\_threads](#)

|                     |                                            |
|---------------------|--------------------------------------------|
| Command-Line Format | <code>--mysqlx-min-worker-threads=#</code> |
| Introduced          | 5.7.12                                     |
| System Variable     | <a href="#">mysqlx_min_worker_threads</a>  |
| Scope               | Global                                     |
| Dynamic             | Yes                                        |
| Type                | Integer                                    |
| Default Value       | 2                                          |
| Minimum Value       | 1                                          |
| Maximum Value       | 100                                        |

The minimum number of worker threads used by X Plugin for handling client requests.

- [mysqlx\\_port](#)

|                     |                                     |
|---------------------|-------------------------------------|
| Command-Line Format | <code>--mysqlx-port=port_num</code> |
| Introduced          | 5.7.12                              |
| System Variable     | <a href="#">mysqlx_port</a>         |
| Scope               | Global                              |
| Dynamic             | No                                  |
| Type                | Integer                             |
| Default Value       | 33060                               |
| Minimum Value       | 1                                   |
| Maximum Value       | 65535                               |

The network port on which X Plugin listens for TCP/IP connections. This is the X Plugin equivalent of [port](#); see that variable description for more information.

- [mysqlx\\_port\\_open\\_timeout](#)

|                     |                                           |
|---------------------|-------------------------------------------|
| Command-Line Format | <code>--mysqlx-port-open-timeout=#</code> |
| Introduced          | 5.7.17                                    |
| System Variable     | <a href="#">mysqlx_port_open_timeout</a>  |
| Scope               | Global                                    |
| Dynamic             | No                                        |
| Type                | Integer                                   |
| Default Value       | 0                                         |
| Minimum Value       | 0                                         |
| Maximum Value       | 120                                       |

The number of seconds X Plugin waits for a TCP/IP port to become free.

- [mysqlx\\_socket](#)

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--mysqlx-socket=file_name</code> |
| Introduced          | 5.7.15                                 |
| System Variable     | <a href="#">mysqlx_socket</a>          |
| Scope               | Global                                 |
| Dynamic             | No                                     |
| Type                | String                                 |
| Default Value       | <code>/tmp/mysqlx.sock</code>          |

The path to a Unix socket file which X Plugin uses for connections. This setting is only used by MySQL Server when running on Unix operating systems. Clients can use this socket to connect to MySQL Server using X Plugin.

The default `mysqlx_socket` path and file name is based on the default path and file name for the main socket file for MySQL Server, with the addition of an `x` appended to the file name. The default path and file name for the main socket file is `/tmp/mysql.sock`, therefore the default path and file name for the X Plugin socket file is `/tmp/mysqlx.sock`.

If you specify an alternative path and file name for the main socket file at server startup using the `socket` system variable, this does not affect the default for the X Plugin socket file. In this situation, if you want to store both sockets at a single path, you must set the `mysqlx_socket` system variable as well. For example in a configuration file:

```
socket=/home/sockets/mysql/mysqld/mysql.sock
mysqlx_socket=/home/sockets/xplugin/xplugin.sock
```

If you change the default path and file name for the main socket file at compile time using the `MYSQL_UNIX_ADDR` compile option, this does affect the default for the X Plugin socket file, which is formed by appending an `x` to the `MYSQL_UNIX_ADDR` file name. If you want to set a different default for the X Plugin socket file at compile time, use the `MYSQLX_UNIX_ADDR` compile option.

The `MYSQLX_UNIX_PORT` environment variable can also be used to set a default for the X Plugin socket file at server startup (see [Section 4.9, “Environment Variables”](#)). If you set this environment variable, it overrides the compiled `MYSQLX_UNIX_ADDR` value, but is overridden by the `mysqlx_socket` value.

- [mysqlx\\_ssl\\_ca](#)

|                     |                                        |      |
|---------------------|----------------------------------------|------|
| Command-Line Format | <code>--mysqlx-ssl-ca=file_name</code> | 2923 |
|---------------------|----------------------------------------|------|

|                 |                               |
|-----------------|-------------------------------|
| Introduced      | 5.7.12                        |
| System Variable | <a href="#">mysqlx_ssl_ca</a> |
| Scope           | Global                        |
| Dynamic         | No                            |
| Type            | File name                     |
| Default Value   | NULL                          |

The [mysqlx\\_ssl\\_ca](#) system variable is like [ssl\\_ca](#), except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 19.4.1, “Using Encrypted Connections with X Plugin”](#).

- [mysqlx\\_ssl\\_capath](#)

|                     |                                           |
|---------------------|-------------------------------------------|
| Command-Line Format | <code>--mysqlx-ssl-capath=dir_name</code> |
| Introduced          | 5.7.12                                    |
| System Variable     | <a href="#">mysqlx_ssl_capath</a>         |
| Scope               | Global                                    |
| Dynamic             | No                                        |
| Type                | Directory name                            |
| Default Value       | NULL                                      |

The [mysqlx\\_ssl\\_capath](#) system variable is like [ssl\\_capath](#), except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 19.4.1, “Using Encrypted Connections with X Plugin”](#).

- [mysqlx\\_ssl\\_cert](#)

|                     |                                          |
|---------------------|------------------------------------------|
| Command-Line Format | <code>--mysqlx-ssl-cert=file_name</code> |
| Introduced          | 5.7.12                                   |
| System Variable     | <a href="#">mysqlx_ssl_cert</a>          |
| Scope               | Global                                   |
| Dynamic             | No                                       |
| Type                | File name                                |
| Default Value       | NULL                                     |

The [mysqlx\\_ssl\\_cert](#) system variable is like [ssl\\_cert](#), except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 19.4.1, “Using Encrypted Connections with X Plugin”](#).

- [mysqlx\\_ssl\\_cipher](#)

|                     |                                       |
|---------------------|---------------------------------------|
| Command-Line Format | <code>--mysqlx-ssl-cipher=name</code> |
| Introduced          | 5.7.12                                |
| System Variable     | <a href="#">mysqlx_ssl_cipher</a>     |
| Scope               | Global                                |
| Dynamic             | No                                    |
| Type                | String                                |

|               |                   |
|---------------|-------------------|
| Default Value | <code>NULL</code> |
|---------------|-------------------|

The `mysqlx_ssl_cipher` system variable is like `ssl_cipher`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 19.4.1, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_ssl_crl`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--mysqlx-ssl-crl=file_name</code> |
| Introduced          | 5.7.12                                  |
| System Variable     | <code>mysqlx_ssl_crl</code>             |
| Scope               | Global                                  |
| Dynamic             | No                                      |
| Type                | File name                               |
| Default Value       | <code>NULL</code>                       |

The `mysqlx_ssl_crl` system variable is like `ssl_crl`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 19.4.1, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_ssl_crlpath`

|                     |                                            |
|---------------------|--------------------------------------------|
| Command-Line Format | <code>--mysqlx-ssl-crlpath=dir_name</code> |
| Introduced          | 5.7.12                                     |
| System Variable     | <code>mysqlx_ssl_crlpath</code>            |
| Scope               | Global                                     |
| Dynamic             | No                                         |
| Type                | Directory name                             |
| Default Value       | <code>NULL</code>                          |

The `mysqlx_ssl_crlpath` system variable is like `ssl_crlpath`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 19.4.1, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_ssl_key`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--mysqlx-ssl-key=file_name</code> |
| Introduced          | 5.7.12                                  |
| System Variable     | <code>mysqlx_ssl_key</code>             |
| Scope               | Global                                  |
| Dynamic             | No                                      |
| Type                | File name                               |
| Default Value       | <code>NULL</code>                       |

The `mysqlx_ssl_key` system variable is like `ssl_key`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 19.4.1, “Using Encrypted Connections with X Plugin”](#).

### 19.4.2.3 X Plugin Status Variables

The X Plugin status variables have the following meanings.

- [Mysqlx\\_address](#)

The network address which X Plugin is bound to. If the bind has failed, or if the `skip_networking` option has been used, the value shows `UNDEFINED`.

- [Mysqlx\\_bytes\\_received](#)

The number of bytes received through the network.

- [Mysqlx\\_bytes\\_sent](#)

The number of bytes sent through the network.

- [Mysqlx\\_connection\\_accept\\_errors](#)

The number of connections which have caused accept errors.

- [Mysqlx\\_connection\\_errors](#)

The number of connections which have caused errors.

- [Mysqlx\\_connections\\_accepted](#)

The number of connections which have been accepted.

- [Mysqlx\\_connections\\_closed](#)

The number of connections which have been closed.

- [Mysqlx\\_connections\\_rejected](#)

The number of connections which have been rejected.

- [Mysqlx\\_crud\\_create\\_view](#)

The number of create view requests received.

- [Mysqlx\\_crud\\_delete](#)

The number of delete requests received.

- [Mysqlx\\_crud\\_drop\\_view](#)

The number of drop view requests received.

- [Mysqlx\\_crud\\_find](#)

The number of find requests received.

- [Mysqlx\\_crud\\_insert](#)

The number of insert requests received.

- [Mysqlx\\_crud\\_modify\\_view](#)

The number of modify view requests received.

- [Mysqlx\\_crud\\_update](#)

The number of update requests received.

- [Mysqlx\\_errors\\_sent](#)

The number of errors sent to clients.

- `Mysqlx_expect_close`

The number of expectation blocks closed.

- `Mysqlx_expect_open`

The number of expectation blocks opened.

- `Mysqlx_init_error`

The number of errors during initialisation.

- `Mysqlx_notice_other_sent`

The number of other types of notices sent back to clients.

- `Mysqlx_notice_warning_sent`

The number of warning notices sent back to clients.

- `Mysqlx_port`

The TCP port which X Plugin is listening to. If a network bind has failed, or if the `skip_networking` system variable is enabled, the value shows `UNDEFINED`.

- `Mysqlx_rows_sent`

The number of rows sent back to clients.

- `Mysqlx_sessions`

The number of sessions that have been opened.

- `Mysqlx_sessions_accepted`

The number of session attempts which have been accepted.

- `Mysqlx_sessions_closed`

The number of sessions that have been closed.

- `Mysqlx_sessions_fatal_error`

The number of sessions that have closed with a fatal error.

- `Mysqlx_sessions_killed`

The number of sessions which have been killed.

- `Mysqlx_sessions_rejected`

The number of session attempts which have been rejected.

- `Mysqlx_socket`

The Unix socket which X Plugin is listening to.

- `Mysqlx_ssl_accept_renegotiates`

The number of negotiations needed to establish the connection.

- `Mysqlx_ssl_accepts`

The number of accepted SSL connections.

- `Mysqlx_ssl_active`  
If SSL is active.
- `Mysqlx_ssl_cipher`  
The current SSL cipher (empty for non-SSL connections).
- `Mysqlx_ssl_cipher_list`  
A list of possible SSL ciphers (empty for non-SSL connections).
- `Mysqlx_ssl_ctx_verify_depth`  
The certificate verification depth limit currently set in ctx.
- `Mysqlx_ssl_ctx_verify_mode`  
The certificate verification mode currently set in ctx.
- `Mysqlx_ssl_finished_accepts`  
The number of successful SSL connections to the server.
- `Mysqlx_ssl_server_not_after`  
The last date for which the SSL certificate is valid.
- `Mysqlx_ssl_server_not_before`  
The first date for which the SSL certificate is valid.
- `Mysqlx_ssl_verify_depth`  
The certificate verification depth for SSL connections.
- `Mysqlx_ssl_verify_mode`  
The certificate verification mode for SSL connections.
- `Mysqlx_ssl_version`  
The name of the protocol used for SSL connections.
- `Mysqlx_stmt_create_collection`  
The number of create collection statements received.
- `Mysqlx_stmt_create_collection_index`  
The number of create collection index statements received.
- `Mysqlx_stmt_disable_notices`  
The number of disable notice statements received.
- `Mysqlx_stmt_drop_collection`  
The number of drop collection statements received.
- `Mysqlx_stmt_drop_collection_index`  
The number of drop collection index statements received.
- `Mysqlx_stmt_enable_notices`

The number of enable notice statements received.

- `Mysqlx_stmt_ensure_collection`

The number of ensure collection statements received.

- `Mysqlx_stmt_execute_mysqlx`

The number of StmtExecute messages received with namespace set to `mysqlx`.

- `Mysqlx_stmt_execute_sql`

The number of StmtExecute requests received for the SQL namespace.

- `Mysqlx_stmt_execute_xplugin`

The number of StmtExecute requests received for the X Plugin namespace.

- `Mysqlx_stmt_kill_client`

The number of kill client statements received.

- `Mysqlx_stmt_list_clients`

The number of list client statements received.

- `Mysqlx_stmt_list_notices`

The number of list notice statements received.

- `Mysqlx_stmt_list_objects`

The number of list object statements received.

- `Mysqlx_stmt_ping`

The number of ping statements received.

- `Mysqlx_worker_threads`

The number of worker threads available.

- `Mysqlx_worker_threads_active`

The number of worker threads currently used.

### 19.4.3 Monitoring X Plugin

To monitor X Plugin, use the status variables that it exposes. See [Section 19.4.2.3, “X Plugin Status Variables”](#).

---

# Chapter 20 InnoDB Cluster

This chapter introduces MySQL InnoDB Cluster, which combines MySQL technologies to enable you to deploy and administer a complete integrated high availability solution for MySQL. This content is a high-level overview of InnoDB Cluster, for full documentation, see [MySQL InnoDB Cluster](#).

## Important

InnoDB Cluster does not provide support for MySQL NDB Cluster. For more information about MySQL NDB Cluster, see [Chapter 21, MySQL NDB Cluster 7.5 and NDB Cluster 7.6](#) and [Section 21.1.6, “MySQL Server Using InnoDB Compared with NDB Cluster”](#).

An InnoDB Cluster consists of at least three MySQL Server instances, and it provides high-availability and scaling features. InnoDB Cluster uses the following MySQL technologies:

- [MySQL Shell](#), which is an advanced client and code editor for MySQL.
- MySQL Server, and [Group Replication](#), which enables a set of MySQL instances to provide high-availability. InnoDB Cluster provides an alternative, easy to use programmatic way to work with Group Replication.
- [MySQL Router](#), a lightweight middleware that provides transparent routing between your application and InnoDB Cluster.

The following diagram shows an overview of how these technologies work together:

Figure 20.1 InnoDB Cluster overview

Being built on MySQL [Group Replication](#), provides features such as automatic membership management, fault tolerance, automatic failover, and so on. An InnoDB Cluster usually runs in a single-primary mode, with one primary instance (read-write) and multiple secondary instances (read-only). Advanced users can also take advantage of a [multi-primary](#) mode, where all instances are primaries.

You work with InnoDB Cluster using the [AdminAPI](#), provided as part of MySQL Shell. AdminAPI is available in JavaScript and Python, and is well suited to scripting and automation of deployments of MySQL to achieve high-availability and scalability. By using MySQL Shell's AdminAPI, you can avoid the need to configure many instances manually. Instead, AdminAPI provides an effective modern interface to sets of MySQL instances and enables you to provision, administer, and monitor your deployment from one central tool.

---

To get started with InnoDB Cluster you need to [download](#) and [install](#) MySQL Shell. You need some hosts with MySQL Server instances [installed](#), and you can also [install](#) MySQL Router.

InnoDB Cluster supports [MySQL Clone](#), which enables you to provision instances simply. In the past, to provision a new instance before it joins a set of MySQL instances you would need to somehow manually transfer the transactions to the joining instance. This could involve making file copies, manually copying them, and so on. Using InnoDB Cluster, you can simply [add an instance](#) to the cluster and it is automatically provisioned.

Similarly, InnoDB Cluster is tightly integrated with [MySQL Router](#), and you can use AdminAPI to [work with](#) them together. MySQL Router can automatically configure itself based on an InnoDB Cluster, in a process called [bootstrapping](#), which removes the need for you to configure routing manually. MySQL Router then transparently connects client applications to the InnoDB Cluster, providing routing and load-balancing for client connections. This integration also enables you to administer some aspects of a MySQL Router bootstrapped against an InnoDB Cluster using AdminAPI. InnoDB Cluster status information includes details about MySQL Routers bootstrapped against the cluster. Operations enable you to [create MySQL Router users](#) at the cluster level, to work with the MySQL Routers bootstrapped against the cluster, and so on.

AdminAPI is compatible with instances running MySQL 5.7, but with a reduced feature set. For more information, see [Using Instances Running MySQL 5.7](#). For the best experience using AdminAPI and InnoDB Cluster [upgrade](#) to MySQL 8.0.

For more information on these technologies, see the user documentation linked in the descriptions. In addition to this user documentation, there is developer documentation for all AdminAPI methods in the MySQL Shell JavaScript API Reference or MySQL Shell Python API Reference, available from [Connectors and APIs](#).

---

# Chapter 21 MySQL NDB Cluster 7.5 and NDB Cluster 7.6

## Table of Contents

|                                                                                           |      |
|-------------------------------------------------------------------------------------------|------|
| 21.1 NDB Cluster Overview .....                                                           | 2939 |
| 21.1.1 NDB Cluster Core Concepts .....                                                    | 2940 |
| 21.1.2 NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions .....            | 2942 |
| 21.1.3 NDB Cluster Hardware, Software, and Networking Requirements .....                  | 2945 |
| 21.1.4 What is New in NDB Cluster .....                                                   | 2947 |
| 21.1.5 NDB: Added, Deprecated, and Removed Options, Variables, and Parameters .....       | 2963 |
| 21.1.6 MySQL Server Using InnoDB Compared with NDB Cluster .....                          | 2966 |
| 21.1.7 Known Limitations of NDB Cluster .....                                             | 2969 |
| 21.2 NDB Cluster Installation .....                                                       | 2980 |
| 21.2.1 Installation of NDB Cluster on Linux .....                                         | 2983 |
| 21.2.2 Installing NDB Cluster on Windows .....                                            | 2991 |
| 21.2.3 Initial Configuration of NDB Cluster .....                                         | 3000 |
| 21.2.4 Initial Startup of NDB Cluster .....                                               | 3002 |
| 21.2.5 NDB Cluster Example with Tables and Data .....                                     | 3003 |
| 21.2.6 Safe Shutdown and Restart of NDB Cluster .....                                     | 3006 |
| 21.2.7 Upgrading and Downgrading NDB Cluster .....                                        | 3007 |
| 21.2.8 The NDB Cluster Auto-Installer (NDB 7.5) (No longer supported) .....               | 3011 |
| 21.2.9 The NDB Cluster Auto-Installer (NDB 7.6) (No longer supported) .....               | 3022 |
| 21.3 Configuration of NDB Cluster .....                                                   | 3043 |
| 21.3.1 Quick Test Setup of NDB Cluster .....                                              | 3044 |
| 21.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables .....     | 3046 |
| 21.3.3 NDB Cluster Configuration Files .....                                              | 3064 |
| 21.3.4 Using High-Speed Interconnects with NDB Cluster .....                              | 3214 |
| 21.4 NDB Cluster Programs .....                                                           | 3214 |
| 21.4.1 ndbd — The NDB Cluster Data Node Daemon .....                                      | 3215 |
| 21.4.2 ndbinfo_select_all — Select From ndbinfo Tables .....                              | 3225 |
| 21.4.3 ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded) .....                   | 3230 |
| 21.4.4 ndb_mgmd — The NDB Cluster Management Server Daemon .....                          | 3231 |
| 21.4.5 ndb_mgm — The NDB Cluster Management Client .....                                  | 3242 |
| 21.4.6 ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables ..... | 3247 |
| 21.4.7 ndb_config — Extract NDB Cluster Configuration Information .....                   | 3253 |
| 21.4.8 ndb_cpcd — Automate Testing for NDB Development .....                              | 3265 |
| 21.4.9 ndb_delete_all — Delete All Rows from an NDB Table .....                           | 3265 |
| 21.4.10 ndb_desc — Describe NDB Tables .....                                              | 3270 |
| 21.4.11 ndb_drop_index — Drop Index from an NDB Table .....                               | 3279 |
| 21.4.12 ndb_drop_table — Drop an NDB Table .....                                          | 3284 |
| 21.4.13 ndb_error_reporter — NDB Error-Reporting Utility .....                            | 3288 |
| 21.4.14 ndb_import — Import CSV Data Into NDB .....                                       | 3289 |
| 21.4.15 ndb_index_stat — NDB Index Statistics Utility .....                               | 3306 |
| 21.4.16 ndb_move_data — NDB Data Copy Utility .....                                       | 3315 |
| 21.4.17 ndb_perror — Obtain NDB Error Message Information .....                           | 3321 |
| 21.4.18 ndb_print_backup_file — Print NDB Backup File Contents .....                      | 3323 |
| 21.4.19 ndb_print_file — Print NDB Disk Data File Contents .....                          | 3323 |
| 21.4.20 ndb_print_frag_file — Print NDB Fragment List File Contents .....                 | 3324 |
| 21.4.21 ndb_print_schema_file — Print NDB Schema File Contents .....                      | 3325 |
| 21.4.22 ndb_print_sys_file — Print NDB System File Contents .....                         | 3325 |
| 21.4.23 ndb_redo_log_reader — Check and Print Content of Cluster Redo Log .....           | 3325 |
| 21.4.24 ndb_restore — Restore an NDB Cluster Backup .....                                 | 3328 |
| 21.4.25 ndb_select_all — Print Rows from an NDB Table .....                               | 3356 |
| 21.4.26 ndb_select_count — Print Row Counts for NDB Tables .....                          | 3363 |

|                                                                                                           |             |
|-----------------------------------------------------------------------------------------------------------|-------------|
| 21.4.27 <code>ndb_setup.py</code> — Start browser-based Auto-Installer for NDB Cluster (DEPRECATED) ..... | 3367        |
| 21.4.28 <code>ndb_show_tables</code> — Display List of NDB Tables .....                                   | 3370        |
| 21.4.29 <code>ndb_size.pl</code> — NDBCLUSTER Size Requirement Estimator .....                            | 3375        |
| 21.4.30 <code>ndb_top</code> — View CPU usage information for NDB threads .....                           | 3378        |
| 21.4.31 <code>ndb_waiter</code> — Wait for NDB Cluster to Reach a Given Status .....                      | 3384        |
| <b>21.5 Management of NDB Cluster .....</b>                                                               | <b>3390</b> |
| 21.5.1 Commands in the NDB Cluster Management Client .....                                                | 3391        |
| 21.5.2 NDB Cluster Log Messages .....                                                                     | 3396        |
| 21.5.3 Event Reports Generated in NDB Cluster .....                                                       | 3411        |
| 21.5.4 Summary of NDB Cluster Start Phases .....                                                          | 3422        |
| 21.5.5 Performing a Rolling Restart of an NDB Cluster .....                                               | 3423        |
| 21.5.6 NDB Cluster Single User Mode .....                                                                 | 3425        |
| 21.5.7 Adding NDB Cluster Data Nodes Online .....                                                         | 3426        |
| 21.5.8 Online Backup of NDB Cluster .....                                                                 | 3437        |
| 21.5.9 MySQL Server Usage for NDB Cluster .....                                                           | 3441        |
| 21.5.10 NDB Cluster Disk Data Tables .....                                                                | 3442        |
| 21.5.11 Online Operations with ALTER TABLE in NDB Cluster .....                                           | 3448        |
| 21.5.12 Distributed Privileges Using Shared Grant Tables .....                                            | 3451        |

MySQL NDB Cluster is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. The most recent NDB Cluster release series uses version 8 of the NDB storage engine (also known as `NDBCLUSTER`) to enable running several computers with MySQL servers and other software in a cluster. NDB Cluster 8.0, now available as a General Availability (GA) release beginning with version 8.0.19, incorporates version 8.0 of the NDB storage engine. NDB Cluster 7.6 and NDB Cluster 7.5, still available as GA releases, use versions 7.6 and 7.5 of NDB, respectively. Previous GA releases still available for use in production, NDB Cluster 7.4 and NDB Cluster 7.3, incorporate NDB versions 7.4 and 7.3, respectively. *NDB 7.2 and older release series are no longer supported or maintained.*

Support for the NDB storage engine is not included in standard MySQL Server 5.7 binaries built by Oracle. Instead, users of NDB Cluster binaries from Oracle should upgrade to the most recent binary release of NDB Cluster for supported platforms—these include RPMs that should work with most Linux distributions. NDB Cluster users who build from source should use the sources provided for NDB Cluster. (Locations where the sources can be obtained are listed later in this section.)

#### Important

MySQL NDB Cluster does not support InnoDB Cluster, which must be deployed using MySQL Server 5.7 with the InnoDB storage engine as well as additional

applications that are not included in the NDB Cluster distribution. MySQL Server 5.7 binaries cannot be used with MySQL NDB Cluster. For more information about deploying and using InnoDB Cluster, see [Using MySQL AdminAPI](#). [Section 21.1.6, “MySQL Server Using InnoDB Compared with NDB Cluster”](#), discusses differences between the `NDB` and `InnoDB` storage engines.

This chapter contains information about NDB Cluster 7.5 releases through 5.7.33-ndb-7.5.23 and NDB Cluster 7.6 releases through 5.7.33-ndb-7.6.19, both of which are General Availability (GA) releases supported in production. The latest available releases of these are 5.7.33-ndb-7.5.22 and 5.7.33-ndb-7.6.18, respectively. NDB Cluster 8.0 is the current GA release and recommended for new deployments; for information about NDB Cluster 8.0, see [What is New in NDB Cluster](#). For similar information about NDB Cluster 7.5 and 7.6, see [Section 21.1.4, “What is New in NDB Cluster”](#). NDB Cluster 7.4 and 7.3 are previous GA releases still supported in production; see [MySQL NDB Cluster 7.3 and NDB Cluster 7.4](#).

**Supported Platforms.** NDB Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to <https://www.mysql.com/support/supportedplatforms/cluster.html>.

**Availability.** NDB Cluster binary and source packages are available for supported platforms from <https://dev.mysql.com/downloads/cluster/>.

**NDB Cluster release numbers.** NDB Cluster follows a somewhat different release pattern from the mainline MySQL Server 5.7 series of releases. In this *Manual* and other MySQL documentation, we identify these and later NDB Cluster releases employing a version number that begins with “NDB”. This version number is that of the `NDBCCLUSTER` storage engine used in the release, and not of the MySQL server version on which the NDB Cluster release is based.

**Version strings used in NDB Cluster software.** The version string displayed by NDB Cluster programs uses this format:

```
mysql-<mysql_server_version>-ndb-<ndb_engine_version>
```

`mysql_server_version` represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 7.5 and NDB Cluster 7.6 releases, this is “5.7”. `ndb_engine_version` is the version of the `NDB` storage engine used by this release of the NDB Cluster software. You can see this format used in the `mysql` client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 5.7.33-ndb-7.5.23 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT VERSION()\G
***** 1. row *****
VERSION(): 5.7.33-ndb-7.5.23
1 row in set (0.00 sec)
```

This version string is also displayed in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=1 @10.0.10.6 (5.7.33-ndb-7.5.23, Nodegroup: 0, *)
id=2 @10.0.10.8 (5.7.33-ndb-7.5.23, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=3 @10.0.10.2 (5.7.33-ndb-7.5.23)

[mysqld(API)] 2 node(s)
```

```
id=4 @10.0.10.10 (5.7.33-ndb-7.5.23)
id=5 (not connected, accepting connect from any host)
```

The version string identifies the mainline MySQL version from which the NDB Cluster release was branched and the version of the `NDB` storage engine used. For example, the full version string for NDB 7.5.4 (the first NDB 7.5 GA release) was `mysql-5.7.16-ndb-7.5.4`. From this we can determine the following:

- Since the portion of the version string preceding `-ndb-` is the base MySQL Server version, this means that NDB 7.5.4 derived from MySQL 5.7.16, and contained all feature enhancements and bug fixes from MySQL 5.7 up to and including MySQL 5.7.16.
- Since the portion of the version string following `-ndb-` represents the version number of the `NDB` (or `NDBCLUSTER`) storage engine, NDB 7.5.4 used version 7.5.4 of the `NDBCLUSTER` storage engine.

New NDB Cluster releases are numbered according to updates in the `NDB` storage engine, and do not necessarily correspond in a one-to-one fashion with mainline MySQL Server releases. For example, NDB 7.5.4 (as previously noted) was based on MySQL 5.7.16, while NDB 7.5.3 was based on MySQL 5.7.13 (version string: `mysql-5.7.13-ndb-7.5.3`).

**Compatibility with standard MySQL 5.7 releases.** While many standard MySQL schemas and applications can work using NDB Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using NDB Cluster (see [Section 21.1.7, “Known Limitations of NDB Cluster”](#)). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, `MyISAM` or `InnoDB`—to use the `NDB` storage engine without allowing for the possibility of changes in schemas, queries, and applications. In addition, the MySQL Server and NDB Cluster codebases diverge considerably, so that the standard `mysqld` cannot function as a drop-in replacement for the version of `mysqld` supplied with NDB Cluster.

**NDB Cluster development source trees.** NDB Cluster development trees can also be accessed from <https://github.com/mysql/mysql-server>.

The NDB Cluster development sources maintained at <https://github.com/mysql/mysql-server> are licensed under the GPL. For information about obtaining MySQL sources using Git and building them yourself, see [Section 2.9.5, “Installing MySQL Using a Development Source Tree”](#).

#### Note

As with MySQL Server 5.7, NDB Cluster 7.5 and NDB Cluster 7.6 releases are built using `CMake`.

NDB Cluster 8.0 is available beginning with NDB 8.0.19 as a General Availability release, and is recommended for new deployments; see [What is New in NDB Cluster](#), for more information. NDB Cluster 7.6 and 7.5 are previous GA releases still supported in production. NDB Cluster 7.4 and 7.3 are previous GA releases still supported in production, although we recommend that new deployments for production use NDB Cluster 8.0; see [MySQL NDB Cluster 7.3 and NDB Cluster 7.4](#).

The contents of this chapter are subject to revision as NDB Cluster continues to evolve. Additional information regarding NDB Cluster can be found on the MySQL website at <http://www.mysql.com/products/cluster/>.

**Additional Resources.** More information about NDB Cluster can be found in the following places:

- For answers to some commonly asked questions about NDB Cluster, see [Section A.10, “MySQL 5.7 FAQ: NDB Cluster”](#).
- The NDB Cluster Forum: <https://forums.mysql.com/list.php?25>.
- Many NDB Cluster users and developers blog about their experiences with NDB Cluster, and make feeds of these available through [PlanetMySQL](#).

## 21.1 NDB Cluster Overview

*NDB Cluster* is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

NDB Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

NDB Cluster integrates the standard MySQL server with an in-memory clustered storage engine called **NDB** (which stands for “*Network DataBase*”). In our documentation, the term **NDB** refers to the part of the setup that is specific to the storage engine, whereas “MySQL NDB Cluster” refers to the combination of one or more MySQL servers with the **NDB** storage engine.

An NDB Cluster consists of a set of computers, known as *hosts*, each running one or more processes. These processes, known as *nodes*, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in an NDB Cluster is shown here:

**Figure 21.1 NDB Cluster Components**

All these programs work together to form an NDB Cluster (see [Section 21.4, “NDB Cluster Programs”](#)). When data is stored by the **NDB** storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although an NDB Cluster SQL node uses the `mysqld` server daemon, it differs in a number of critical respects from the `mysqld` binary supplied with the MySQL 5.7 distributions, and the two versions of `mysqld` are not interchangeable.

In addition, a MySQL server that is not connected to an NDB Cluster cannot use the **NDB** storage engine and cannot access any NDB Cluster data.

The data stored in the data nodes for NDB Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see [Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)). Rolling restarts are also used as part of the process of adding new data nodes online (see [Section 21.5.7, “Adding NDB Cluster Data Nodes Online”](#)). For more information about data nodes, how they are organized in an NDB Cluster, and how they handle and store NDB Cluster data, see [Section 21.1.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#).

Backing up and restoring NDB Cluster databases can be done using the `NDB`-native functionality found in the NDB Cluster management client and the `ndb_restore` program included in the NDB Cluster distribution. For more information, see [Section 21.5.8, “Online Backup of NDB Cluster”](#), and [Section 21.4.24, “`ndb\_restore` — Restore an NDB Cluster Backup”](#). You can also use the standard MySQL functionality provided for this purpose in `mysqldump` and the MySQL server. See [Section 4.5.4, “`mysqldump` — A Database Backup Program”](#), for more information.

NDB Cluster nodes can employ different transport mechanisms for inter-node communications; TCP/IP over standard 100 Mbps or faster Ethernet hardware is used in most real-world deployments.

## 21.1.1 NDB Cluster Core Concepts

`NDBCLUSTER` (also known as `NDB`) is an in-memory storage engine offering high-availability and data-persistence features.

The `NDBCLUSTER` storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. NDB Cluster’s `NDB` storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of NDB Cluster is configured independently of the MySQL servers. In an NDB Cluster, each part of the cluster is considered to be a *node*.

### Note

In many contexts, the term “node” is used to indicate a computer, but when discussing NDB Cluster it means a *process*. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

There are three types of cluster nodes, and in a minimal NDB Cluster configuration, there must be at least three nodes, one of each of these types:

- *Management node*: The role of this type of node is to manage the other nodes within the NDB Cluster, performing such functions as providing configuration data, starting and stopping nodes, and running backups. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. A management node is started with the command `ndb_mgmd`.
- *Data node*: This type of node stores cluster data. There are as many data nodes as there are fragment replicas, times the number of fragments (see [Section 21.1.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#)). For example, with two fragment replicas, each having two fragments, you need four data nodes. One fragment replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have two (or more) fragment replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see [Section 21.4.1, “`ndbd` — The NDB Cluster Data Node Daemon”](#)) or `ndbmttd` (see [Section 21.4.3, “`ndbmttd` — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#)).

NDB Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to NDB Cluster as an *in-memory* database). However, some NDB Cluster data can be stored on disk; see [Section 21.5.10, “NDB Cluster Disk Data Tables”](#), for more information.

- *SQL node*: This is a node that accesses the cluster data. In the case of NDB Cluster, an SQL node is a traditional MySQL server that uses the `NDBCLUSTER` storage engine. An SQL node is a `mysqld`

process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of *API node*, which designates any application which accesses NDB Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see [Getting Started with the NDB API](#).

### Important

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from NDB Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, fragment replicas, and partitions in NDB Cluster, see [Section 21.1.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#).

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. NDB Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, NDB-specific API programs, and management clients. These are described in the next few paragraphs.

**Standard MySQL clients.** NDB Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as NDB Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using an NDB Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with NDB Cluster, see [Using Connector/J with NDB Cluster](#).

**NDB client programs.** Client programs can be written that access NDB Cluster data directly from the `NDBCLUSTER` storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the *NDB API*, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see [The NDB API](#).

NDB-specific Java applications can also be written for NDB Cluster using the *NDB Cluster Connector for Java*. This NDB Cluster Connector includes *ClusterJ*, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to `NDBCLUSTER`, and so does not require access to a MySQL Server. See [Java and NDB Cluster](#), and [The ClusterJ API and Data Object Model](#), for more information.

**Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions

only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the `ndb_mgm` management client supplied with NDB Cluster (see [Section 21.4.5, “`ndb\_mgm` — The NDB Cluster Management Client”](#)). Such applications can be written using the *MGM API*, a C-language API that communicates directly with one or more NDB Cluster management servers. For more information, see [The MGM API](#).

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex NDB Cluster management tasks, such restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to NDB Cluster. See [MySQL™ Cluster Manager 1.4.8 User Manual](#), for more information.

**Event logs.** NDB Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in [Section 21.5.3, “Event Reports Generated in NDB Cluster”](#). Event logs are of the two types listed here:

- *Cluster log*: Keeps a record of all desired reportable events for the cluster as a whole.
- *Node log*: A separate log which is also kept for each individual node.

#### Note

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

**Checkpoint.** Generally speaking, when data is saved to disk, it is said that a *checkpoint* has been reached. More specific to NDB Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the `NDB` storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained. These are shown in the following list:

- *Local Checkpoint (LCP)*: This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP usually occurs every few minutes; the precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

Prior to NDB 7.6.4, an LCP involved saving all of a node's data to disk. NDB 7.6.4 introduces support for partial LCPs, which can significantly improve recovery time under some conditions. See [Section 21.1.4.2, “What is New in NDB Cluster 7.6”](#), for more information, as well as the descriptions of the `EnablePartialLcp` and `RecoveryWork` configuration parameters which enable partial LCPs and control the amount of storage they use.

- *Global Checkpoint (GCP)*: A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see [NDB Cluster Data Node File System Directory](#).

## 21.1.2 NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions

This section discusses the manner in which NDB Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

**Data node.** An `ndbd` or `ndbmttd` process, which stores one or more *fragment replicas*—that is, copies of the *partitions* (discussed later in this section) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple data node processes on a single computer, such a configuration is not usually recommended.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` or `ndbmttd` process; where mentioned, management nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

**Node group.** A node group consists of one or more nodes, and stores partitions, or sets of *fragment replicas* (see next item).

The number of node groups in an NDB Cluster is not directly configurable; it is a function of the number of data nodes and of the number of fragment replicas (`NoOfReplicas` configuration parameter), as shown here:

```
[# of node groups] = [# of data nodes] / NoOfReplicas
```

Thus, an NDB Cluster with 4 data nodes has 4 node groups if `NoOfReplicas` is set to 1 in the `config.ini` file, 2 node groups if `NoOfReplicas` is set to 2, and 1 node group if `NoOfReplicas` is set to 4. Fragment replicas are discussed later in this section; for more information about `NoOfReplicas`, see [Section 21.3.3.6, “Defining NDB Cluster Data Nodes”](#).

#### Note

All node groups in an NDB Cluster must have the same number of data nodes.

You can add new node groups (and thus new data nodes) online, to a running NDB Cluster; see [Section 21.5.7, “Adding NDB Cluster Data Nodes Online”](#), for more information.

**Partition.** This is a portion of the data stored by the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one fragment replica) available to the cluster.

The number of partitions used by default by NDB Cluster depends on the number of data nodes and the number of LDM threads in use by the data nodes, as shown here:

```
[# of partitions] = [# of data nodes] * [# of LDM threads]
```

When using data nodes running `ndbmttd`, the number of LDM threads is controlled by the setting for `MaxNoOfExecutionThreads`. When using `ndbd` there is a single LDM thread, which means that there are as many cluster partitions as nodes participating in the cluster. This is also the case when using `ndbmttd` with `MaxNoOfExecutionThreads` set to 3 or less. (You should be aware that the number of LDM threads increases with the value of this parameter, but not in a strictly linear fashion, and that there are additional constraints on setting it; see the description of `MaxNoOfExecutionThreads` for more information.)

**NDB and user-defined partitioning.** NDB Cluster normally partitions `NDBCLUSTER` tables automatically. However, it is also possible to employ user-defined partitioning with `NDBCLUSTER` tables. This is subject to the following limitations:

1. Only the `KEY` and `LINEAR KEY` partitioning schemes are supported in production with `NDB` tables.
2. The maximum number of partitions that may be defined explicitly for any `NDB` table is  $8 * [number\ of\ LDM\ threads] * [number\ of\ node\ groups]$ , the number of node groups in an NDB Cluster being determined as discussed previously in this section. When running `ndbd` for data node processes, setting the number of LDM threads has no effect (since `ThreadConfig` applies only to `ndbmttd`); in such cases, this value can be treated as though it were equal to 1 for purposes of performing this calculation.

See [Section 21.4.3, “ndbmttd — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#), for more information.

For more information relating to NDB Cluster and user-defined partitioning, see [Section 21.1.7, “Known Limitations of NDB Cluster”](#), and [Section 22.6.2, “Partitioning Limitations Relating to Storage Engines”](#).

**Fragment replica.** This is a copy of a cluster partition. Each node in a node group stores a fragment replica. Also sometimes known as a *partition replica*. The number of fragment replicas is equal to the number of nodes per node group.

A fragment replica belongs entirely to a single node; a node can (and usually does) store several fragment replicas.

The following diagram illustrates an NDB Cluster with four data nodes running `ndbd`, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1.

 **Note**  
Only data nodes are shown here; although a working NDB Cluster requires an `ndb_mgmd` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted from the figure for clarity.

**Figure 21.2 NDB Cluster with Two Node Groups**

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a *primary fragment replica* (primary copy) is stored on node 1, and a *backup fragment replica* (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary fragment replica is on node 3, and its backup fragment replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two fragment replicas is reversed from that of Partition 0; for Partition 2, the primary fragment replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two fragment replicas are reversed from those of partition 1. That is, its primary fragment replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of an NDB Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

**Figure 21.3 Nodes Required for a 2x2 NDB Cluster**

In this example, the cluster consists of two node groups each consisting of two data nodes. Each data node is running an instance of `ndbd`. Any combination of at least one node from node group 0 and at least one node from node group 1 is sufficient to keep the cluster “alive”. However, if both nodes from a single node group fail, the combination consisting of the remaining two nodes in the other node group is not sufficient. In this situation, the cluster has lost an entire partition and so can no longer provide access to a complete set of all NDB Cluster data.

In NDB 7.5.4 and later, the maximum number of node groups supported for a single NDB Cluster instance is 48 (Bug#80845, Bug #22996305).

### 21.1.3 NDB Cluster Hardware, Software, and Networking Requirements

One of the strengths of NDB Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see [Section 21.5.10, “NDB Cluster Disk Data Tables”](#), for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other NDB Cluster processes are relatively small.

The software requirements for NDB Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support NDB Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of NDB Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use NDB Cluster. We assume that you are using the binaries appropriate to your platform, available from the NDB Cluster software downloads page at <https://dev.mysql.com/downloads/cluster/>.

For communication between nodes, NDB Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that an NDB Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.** Communications between NDB Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within an NDB Cluster is to run your NDB Cluster on a protected network. If you intend to use NDB Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone ([DMZ](#)) or elsewhere.

See [Section 21.5.17.1, “NDB Cluster Security and Networking Issues”](#), for more information.

- **Efficiency.** Setting up an NDB Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your NDB Cluster not only helps protect against unauthorized access to NDB Cluster data, it also ensures that NDB Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

**Network communication and latency.** NDB Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, NDB Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, an NDB Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as [HeartbeatIntervalDbDb](#) and [HeartbeatIntervalDbApi](#) for NDB Cluster, care must be taken care to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100  $\mu$ s), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing

timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where NDB Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

## 21.1.4 What is New in NDB Cluster

The following sections describe changes in the implementation of NDB Cluster in MySQL NDB Cluster 7.6 through 5.7.33-ndb-7.6.19 and NDB Cluster 7.5 through 5.7.33-ndb-7.5.23 as compared to earlier release series. NDB Cluster 8.0 is available as a General Availability (GA) release, beginning with NDB 8.0.19; see [What is New in NDB Cluster](#), for more information about new features and other changes in NDB 8.0. NDB Cluster 7.6 and 7.5 are previous GA releases still supported in production; for information about NDB Cluster 7.6, see [Section 21.1.4.2, “What is New in NDB Cluster 7.6”](#). For similar information about NDB Cluster 7.5, see [Section 21.1.4.1, “What is New in NDB Cluster 7.5”](#). NDB Cluster 7.4 and 7.3 are previous GA releases still supported in production, although we recommend that new deployments for production use NDB Cluster 8.0; see [MySQL NDB Cluster 7.3 and NDB Cluster 7.4](#).

### 21.1.4.1 What is New in NDB Cluster 7.5

Major changes and new features in NDB Cluster 7.5 which are likely to be of interest are shown in the following list:

- **ndbinfo Enhancements.** A number of changes are made in the `ndbinfo` database, chief of which is that it now provides detailed information about NDB Cluster node configuration parameters.

The `config_params` table has been made read-only, and has been enhanced with additional columns providing information about each configuration parameter, including the parameter's type, default value, maximum and minimum values (where applicable), a brief description of the parameter, and whether the parameter is required. This table also provides each parameter with a unique `param_number`.

A row in the `config_values` table shows the current value of a given parameter on the node having a specified ID. The parameter is identified by the value of the `config_param` column, which maps to the `config_params` table's `param_number`.

Using this relationship you can write a join on these two tables to obtain the default, maximum, minimum, and current values for one or more NDB Cluster configuration parameters by name. An example SQL statement using such a join is shown here:

```
SELECT p.param_name AS Name,
 v.node_id AS Node,
 p.param_type AS Type,
 p.param_default AS 'Default',
 p.param_min AS Minimum,
 p.param_max AS Maximum,
 CASE p.param_mandatory WHEN 1 THEN 'Y' ELSE 'N' END AS 'Required',
 v.config_value AS Current
 FROM config_params p
 JOIN config_values v
 ON p.param_number = v.config_param
 WHERE p.param_name IN ('NodeId', 'HostName', 'DataMemory', 'IndexMemory');
```

For more information about these changes, see [Section 21.5.14.8, “The ndbinfo config\\_params Table”](#). See [Section 21.5.14.9, “The ndbinfo config\\_values Table”](#), for further information and examples.

In addition, the `ndbinfo` database no longer depends on the `MyISAM` storage engine. All `ndbinfo` tables and views now use `NDB` (shown as `NDBINFO`).

Several new `ndbinfo` tables were introduced in NDB 7.5.4. These tables are listed here, with brief descriptions:

- `dict_obj_info` provides the names and types of database objects in `NDB`, as well as information about parent objects where applicable
- `table_distribution_status` provides `NDB` table distribution status information
- `table_fragments` provides information about the distribution of `NDB` table fragments
- `table_info` provides information about logging, checkpointing, storage, and other options in force for each `NDB` table
- `table_replicas` provides information about fragment replicas

See the descriptions of the individual tables for more information.

- **Default row and column format changes.** Starting with NDB 7.5.1, the default value for both the `ROW_FORMAT` option and the `COLUMN_FORMAT` option for `CREATE TABLE` can be set to `DYNAMIC` rather than `FIXED`, using a new MySQL server variable `ndb_default_column_format` is added as part of this change; set this to `FIXED` or `DYNAMIC` (or start `mysqld` with the equivalent option `--ndb-default-column-format=FIXED`) to force this value to be used for `COLUMN_FORMAT` and `ROW_FORMAT`. Prior to NDB 7.5.4, the default for this variable was `DYNAMIC`; in this and later versions, the default is `FIXED`, which provides backwards compatibility with prior releases (Bug #24487363).

The row format and column format used by existing table columns are unaffected by this change. New columns added to such tables use the new defaults for these (possibly overridden by `ndb_default_column_format`), and existing columns are changed to use these as well, provided that the `ALTER TABLE` statement performing this operation specifies `ALGORITHM=COPY`.

#### Note

A copying `ALTER TABLE` cannot be done implicitly if `mysqld` is run with `--ndb-allow-copying-alter-table=FALSE`.

- **`ndb_binlog_index` no longer dependent on MyISAM.** As of NDB 7.5.2, the `ndb_binlog_index` table employed in NDB Cluster Replication now uses the `InnoDB` storage engine instead of `MyISAM`. When upgrading, you can run `mysql_upgrade` with `--force --upgrade-system-tables` to cause it to execute `ALTER TABLE ... ENGINE=INNODB` on this table. Use of `MyISAM` for this table remains supported for backward compatibility.

A benefit of this change is that it makes it possible to depend on transactional behavior and lock-free reads for this table, which can help alleviate concurrency issues during purge operations and log rotation, and improve the availability of this table.

- **ALTER TABLE changes.** NDB Cluster formerly supported an alternative syntax for online `ALTER TABLE`. This is no longer supported in NDB Cluster 7.5, which makes exclusive use of `ALGORITHM = DEFAULT | COPY | INPLACE` for table DDL, as in the standard MySQL Server.

Another change affecting the use of this statement is that `ALTER TABLE ... ALGORITHM=INPLACE RENAME` may now contain DDL operations in addition to the renaming.

- **ExecuteOnComputer parameter deprecated.** The `ExecuteOnComputer` configuration parameter for `management nodes`, `data nodes`, and `API nodes` has been deprecated and is now subject to removal in a future release of NDB Cluster. You should use the equivalent `HostName` parameter for all three types of nodes.

- **records-per-key optimization.** The NDB handler now uses the records-per-key interface for index statistics implemented for the optimizer in MySQL 5.7.5. Some of the benefits from this change include those listed here:
  - The optimizer now chooses better execution plans in many cases where a less optimal join index or table join order would previously have been chosen
  - Row estimates shown by `EXPLAIN` are more accurate
  - Cardinality estimates shown by `SHOW INDEX` are improved
- **Connection pool node IDs.** NDB 7.5.0 adds the `mysqld --ndb-cluster-connection-pool-nodeids` option, which allows a set of node IDs to be set for the connection pool. This setting overrides `--ndb-nodeid`, which means that it also overrides both the `--ndb-connectstring` option and the `NDB_CONNECTSTRING` environment variable.

**Note**

You can set the size for the connection pool using the `--ndb-cluster-connection-pool` option for `mysqld`.

- **create\_old\_temporals removed.** The `create_old_temporals` system variable was deprecated in NDB Cluster 7.4, and has now been removed.
- **ndb\_mgm Client PROMPT command.** NDB Cluster 7.5 adds a new command for setting the client's command-line prompt. The following example illustrates the use of the `PROMPT` command:

```
ndb_mgm> PROMPT mgm#1:
mgm#1: SHOW
Cluster Configuration

[ndbd(NDB)] 4 node(s)
id=5 @10.100.1.1 (mysql-5.7.33-ndb-7.5.23, Nodegroup: 0, *)
id=6 @10.100.1.3 (mysql-5.7.33-ndb-7.5.23, Nodegroup: 0)
id=7 @10.100.1.9 (mysql-5.7.33-ndb-7.5.23, Nodegroup: 1)
id=8 @10.100.1.11 (mysql-5.7.33-ndb-7.5.23, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=50 @10.100.1.8 (mysql-5.7.33-ndb-7.5.23)

[mysqld(API)] 2 node(s)
id=100 @10.100.1.8 (5.7.33-ndb-7.5.23)
id=101 @10.100.1.10 (5.7.33-ndb-7.5.23)

mgm#1: PROMPT
ndb_mgm> EXIT
jon@valhaj:/usr/local/mysql/bin>
```

For additional information and examples, see [Section 21.5.1, “Commands in the NDB Cluster Management Client”](#).

- **Increased FIXED column storage per fragment.** NDB Cluster 7.5 and later supports a maximum of 128 TB per fragment of data in `FIXED` columns. In NDB Cluster 7.4 and earlier, this was 16 GB per fragment.
- **Deprecated parameters removed.** The following NDB Cluster data node configuration parameters were deprecated in previous releases of NDB Cluster, and were removed in NDB 7.5.0:
  - `Id`: deprecated in NDB 7.1.9; replaced by `NodeId`.
  - `NoOfDiskPagesToDiskDuringRestartTUP`, `NoOfDiskPagesToDiskDuringRestartACC`: both deprecated, had no effect; replaced in MySQL 5.1.6 by

`DiskCheckpointSpeedInRestart`, which itself was later deprecated (in NDB 7.4.1) and is now also removed.

- `NoOfDiskPagesToDiskAfterRestartACC`, `NoOfDiskPagesToDiskAfterRestartTUP`: both deprecated, and had no effect; replaced in MySQL 5.1.6 by `DiskCheckpointSpeed`, which itself was later deprecated (in NDB 7.4.1) and is now also removed.
- `ReservedSendBufferMemory`: Deprecated, and no longer had any effect.
- `MaxNoOfIndexes`: archaic (pre-MySQL 4.1), had no effect; long since replaced by `MaxNoOfOrderedIndexes` or `MaxNoOfUniqueHashIndexes`.
- `Diskless`: archaic (pre-MySQL 4.1) synonym for and long since replaced by `Diskless`.

The archaic and unused (and for this reason also previously undocumented) `ByteOrder` computer configuration parameter was also removed in NDB 7.5.0.

The parameters just described are not supported in NDB 7.5. Attempting to use any of these parameters in an NDB Cluster configuration file now results in an error.

- **DBTC scan enhancements.** Scans have been improved by reducing the number of signals used for communication between the `DBTC` and `DBDIH` kernel blocks in `NDB`, enabling higher scalability of data nodes when used for scan operations by decreasing the use of CPU resources for scan operations, in some cases by an estimated five percent.

Also as result of these changes response times should be greatly improved, which could help prevent issues with overload of the main threads. In addition, scans made in the `BACKUP` kernel block have also been improved and made more efficient than in previous releases.

- **JSON column support.** NDB 7.5.2 and later supports the `JSON` column type for `NDB` tables and the JSON functions found in the MySQL Server, subject to the limitation that an `NDB` table can have at most 3 `JSON` columns.

- **Read from any fragment replica; specify number of hashmap partition fragments.**

Previously, all reads were directed towards the primary fragment replica except for simple reads. (A simple read is a read that locks the row while reading it.) Beginning with NDB 7.5.2, it is possible to enable reads from any fragment replica. This is disabled by default but can be enabled for a given SQL node using the `ndb_read_backup` system variable added in this release.

Previously, it was possible to define tables with only one type of partition mapping, with one primary partition on each LDM in each node, but in NDB 7.5.2 it becomes possible to be more flexible about the assignment of partitions by setting a partition balance (fragment count type). Possible balance schemes are one per node, one per node group, one per LDM per node, and one per LDM per node group.

This setting can be controlled for individual tables by means of a `PARTITION_BALANCE` option (renamed from `FRAGMENT_COUNT_TYPE` in NDB 7.5.4) embedded in `NDB_TABLE` comments in `CREATE TABLE` or `ALTER TABLE` statements. Settings for table-level `READ_BACKUP` are also supported using this syntax. For more information and examples, see [Section 13.1.18.9, “Setting NDB\\_TABLE Options”](#).

In NDB API applications, a table's partition balance can also be get and set using methods supplied for this purpose; see `Table::getPartitionBalance()`, and `Table::setPartitionBalance()`, as well as `Object::PartitionBalance`, for more information about these.

As part of this work, NDB 7.5.2 also introduces the `ndb_data_node_neighbour` system variable. This is intended for use, in transaction hinting, to provide a “nearby” data node to this SQL node.

In addition, when restoring table schemas, `ndb_restore --restore-meta` now uses the target cluster's default partitioning, rather than using the same number of partitions as the original cluster

from which the backup was taken. See [Restoring to More Nodes Than the Original](#), for more information and an example.

NDB 7.5.3 adds a further enhancement to `READ_BACKUP`: In this and later versions, it is possible to set `READ_BACKUP` for a given table online as part of `ALTER TABLE ... ALGORITHM=INPLACE ...`

- **ThreadConfig improvements.** A number of enhancements and feature additions are implemented in NDB 7.5.2 for the `ThreadConfig` multithreaded data node (`ndbmt`) configuration parameter, including support for an increased number of platforms. These changes are described in the next few paragraphs.

Non-exclusive CPU locking is now supported on FreeBSD and Windows, using `cpubind` and `cpuset`. Exclusive CPU locking is now supported on Solaris (only) using the `cpubind_exclusive` and `cpuset_exclusive` parameters which are introduced in this release.

Thread prioritization is now available, controlled by the new `thread_prio` parameter. `thread_prio` is supported on Linux, FreeBSD, Windows, and Solaris, and varies somewhat by platform. For more information, see the description of `ThreadConfig`.

The `realtime` parameter is now supported on Windows platforms.

- **Partitions larger than 16 GB.** Due to an improvement in the hash index implementation used by NDB Cluster data nodes, partitions of `NDB` tables may now contain more than 16 GB of data for fixed columns, and the maximum partition size for fixed columns is now raised to 128 TB. The previous limitation was due to the fact that the `DBACC` block in the `NDB` kernel used only 32-bit references to the fixed-size part of a row in the `DBTUP` block, although 45-bit references to this data are used in `DBTUP` itself and elsewhere in the kernel outside `DBACC`; all such references in to the data handled in the `DBACC` block now use 45 bits instead.
- **Print SQL statements from `ndb_restore`.** NDB 7.5.4 adds the `--print-sql-log` option for the `ndb_restore` utility provided with the NDB Cluster distribution. This option enables SQL logging to `stdout`. **Important:** Every table to be restored using this option must have an explicitly defined primary key.

See [Section 21.4.24, “`ndb\_restore` — Restore an NDB Cluster Backup”](#), for more information.

- **Organization of RPM packages.** Beginning with NDB 7.5.4, the naming and organization of RPM packages provided for NDB Cluster align more closely with those released for the MySQL server. The names of all NDB Cluster RPMs are now prefixed with `mysql-cluster`. Data nodes are now installed using the `data-node` package; management nodes are now installed from the `management-server` package; and SQL nodes require the `server` and `common` packages. MySQL and `NDB` client programs, including the `mysql` client and the `ndb_mgm` management client, are now included in the `client` RPM.

For a detailed listing of NDB Cluster RPMs and other information, see [Section 21.2.1.2, “Installing NDB Cluster from RPM”](#).

- **`ndbinfo` processes and `config_nodes` tables.** NDB 7.5.7 adds two tables to the `ndbinfo` information database to provide information about cluster nodes; these tables are listed here:
  - `config_nodes`: This table provides the node ID, process type, and host name for each node listed in an NDB cluster's configuration file.
  - The `processes` shows information about nodes currently connected to the cluster; this information includes the process name and system process ID; for each data node and SQL node, it also shows the process ID of the node's angel process. In addition, the table shows a service address for each connected node; this address can be set in NDB API applications using the `Ndb_cluster_connection::set_service_uri()` method, which is also added in NDB 7.5.7.

- **System name.** The system name of an NDB cluster can be used to identify a specific cluster. Beginning with NDB 7.5.7, the MySQL Server shows this name as the value of the `Ndb_system_name` status variable; NDB API applications can use the `Ndb_cluster_connection::get_system_name()` method which is added in the same release.

A system name based on the time the management server was started is generated automatically; you can override this value by adding a `[system]` section to the cluster's configuration file and setting the `Name` parameter to a value of your choice in this section, prior to starting the management server.

- **ndb\_restore options.** Beginning with NDB 7.5.13, the `--nodeid` and `--backupid` options are both required when invoking `ndb_restore`.
- **ndb\_blob\_tool enhancements.** Beginning with NDB 7.5.18, the `ndb_blob_tool` utility can detect missing blob parts for which inline parts exist and replace these with placeholder blob parts (consisting of space characters) of the correct length. To check whether there are missing blob parts, use the `--check-missing` option with this program. To replace any missing blob parts with placeholders, use the `--add-missing` option.

For more information, see [Section 21.4.6, “ndb\\_blob\\_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables”](#).

- **--ndb-log-fail-terminate option.** Beginning with NDB 7.5.18, you can cause the SQL node to terminate whenever it is unable to log all row events fully. This can be done by starting `mysqld` with the `--ndb-log-fail-terminate` option.
- **NDB programs—NDBT dependency removal.** The dependency of a number of `NDB` utility programs on the `NDBT` library has been removed. This library is used internally for development, and is not required for normal use; its inclusion in these programs could lead to unwanted issues when testing.

Affected programs are listed here, along with the `NDB` versions in which the dependency was removed:

- `ndb_restore`, in NDB 7.5.15
- `ndb_show_tables`, in NDB 7.5.18
- `ndb_waiter`, in NDB 7.5.18

The principal effect of this change for users is that these programs no longer print `NDBT_ProgramExit - status` following completion of a run. Applications that depend upon such behavior should be updated to reflect the change when upgrading to the indicated versions.

- **Auto-Installer deprecation and removal.** The MySQL NDB Cluster Auto-Installer web-based installation tool (`ndb_setup.py`) is deprecated in NDB 7.5.20, and is removed in NDB 7.5.21 and later. It is no longer supported.
- **ndbmempache deprecation and removal.** `ndbmempache` is no longer supported. `ndbmempache` was deprecated in NDB 7.5.20, and removed in NDB 7.5.21.
- **Node.js support removed.** Beginning with the NDB Cluster 7.5.20 release, support for Node.js by NDB 7.5 has been removed.

Support for Node.js by NDB Cluster is maintained in NDB 8.0 only.

- **Conversion between NULL and NOT NULL during restore operations.** Beginning with NDB 7.5.23, `ndb_restore` can support restoring of `NULL` columns as `NOT NULL` and the reverse, using the options listed here:
  - To restore a `NULL` column as `NOT NULL`, use the `--lossy-conversions` option.

The column originally declared as `NULL` must not contain any `NULL` rows; if it does, `ndb_restore` exits with an error.

- To restore a `NOT NULL` column as `NULL`, use the `--promote-attributes` option.

For more information, see the descriptions of the indicated `ndb_restore` options.

ClusterJPA is no longer supported beginning with NDB 7.5.7; its source code and binary have been removed from the NDB Cluster distribution.

NDB Cluster 7.5 is also supported by MySQL Cluster Manager, which provides an advanced command-line interface that can simplify many complex NDB Cluster management tasks. See [MySQL™ Cluster Manager 1.4.8 User Manual](#), for more information.

#### 21.1.4.2 What is New in NDB Cluster 7.6

New features and other important changes in NDB Cluster 7.6 which are likely to be of interest are shown in the following list:

- **New Disk Data table file format.** A new file format was introduced in NDB 7.6.2 for NDB Disk Data tables, which makes it possible for each Disk Data table to be uniquely identified without reusing any table IDs. The format was improved further in NDB 7.6.4. This should help resolve issues with page and extent handling that were visible to the user as problems with rapid creating and dropping of Disk Data tables, and for which the old format did not provide a ready means to fix.

The new format is now used whenever new undo log file groups and tablespace data files are created. Files relating to existing Disk Data tables continue to use the old format until their tablespaces and undo log file groups are re-created.

##### Important

The old and new formats are not compatible; different data files or undo log files that are used by the same Disk Data table or tablespace cannot use a mix of formats.

To avoid problems relating to the changes in format, you should re-create any existing tablespaces and undo log file groups when upgrading to NDB 7.6.2 or NDB 7.6.4. You can do this by performing an initial restart of each data node (that is, using the `--initial` option) as part of the upgrade process. You can expect this step to be made mandatory as part of upgrading from NDB 7.5 or an earlier release series to NDB 7.6 or later.

If you are using Disk Data tables, a downgrade from *any* NDB 7.6 release—without regard to release status—to any NDB 7.5 or earlier release requires that you restart all data nodes with `--initial` as part of the downgrade process. This is because NDB 7.5 and earlier release series are not able to read the new Disk Data file format.

For more information, see [Section 21.2.7, “Upgrading and Downgrading NDB Cluster”](#).

- **Data memory pooling and dynamic index memory.** Memory required for indexes on NDB table columns is now allocated dynamically from that allocated for `DataMemory`. For this reason, the `IndexMemory` configuration parameter is now deprecated, and subject to removal in a future release series.

##### Important

Starting with NDB 7.6.2, if `IndexMemory` is set in the `config.ini` file, the management server issues the warning `IndexMemory is deprecated, use Number bytes on each ndbd(DB) node allocated for storing indexes instead` on startup, and any memory assigned to this parameter is automatically added to `DataMemory`.

In addition, the default value for `DataMemory` has been increased to 98M; the default for `IndexMemory` has been decreased to 0.

The pooling together of index memory with data memory simplifies the configuration of `NDB`; a further benefit of these changes is that scaling up by increasing the number of LDM threads is no longer limited by having set an insufficiently large value for `IndexMemory`. This is because index memory is no longer a static quantity which is allocated only once (when the cluster starts), but can now be allocated and deallocated as required. Previously, it was sometimes the case that increasing the number of LDM threads could lead to index memory exhaustion while large amounts of `DataMemory` remained available.

As part of this work, a number of instances of `DataMemory` usage not directly related to storage of table data now use transaction memory instead.

For this reason, it may be necessary on some systems to increase `SharedGlobalMemory` to allow transaction memory to increase when needed, such as when using NDB Cluster Replication, which requires a great deal of buffering on the data nodes. On systems performing initial bulk loads of data, it may be necessary to break up very large transactions into smaller parts.

In addition, data nodes now generate `MemoryUsage` events (see [Section 21.5.3.2, “NDB Cluster Log Events”](#)) and write appropriate messages in the cluster log when resource usage reaches 99%, as well as when it reaches 80%, 90%, or 100%, as before.

Other related changes are listed here:

- `IndexMemory` is no longer one of the values displayed in the `ndbinfo.memoryusage` table's `memory_type` column; is also no longer displayed in the output of `ndb_config`.
- `REPORT MEMORYUSAGE` and other commands which expose memory consumption now shows index memory consumption using 32K pages (previously these were 8K pages).
- The `ndbinfo.resources` table now shows the `DISK_OPERATIONS` resource as `TRANSACTION_MEMORY`, and the `RESERVED` resource has been removed.
- **ndbinfo processes and config\_nodes tables.** NDB 7.6.2 adds two tables to the `ndbinfo` information database to provide information about cluster nodes; these tables are listed here:
  - `config_nodes`: This table the node ID, process type, and host name for each node listed in an NDB cluster's configuration file.
  - The `processes` shows information about nodes currently connected to the cluster; this information includes the process name and system process ID; for each data node and SQL node, it also shows the process ID of the node's angel process. In addition, the table shows a service address for each connected node; this address can be set in NDB API applications using the `Ndb_cluster_connection::set_service_uri()` method, which is also added in NDB 7.6.2.
- **System name.** The system name of an NDB cluster can be used to identify a specific cluster. Beginning with NDB 7.6.2, the MySQL Server shows this name as the value of the `Ndb_system_name` status variable; NDB API applications can use the `Ndb_cluster_connection::get_system_name()` method which is added in the same release.

A system name based on the time the management server was started is generated automatically>; you can override this value by adding a `[system]` section to the cluster's configuration file and setting the `Name` parameter to a value of your choice in this section, prior to starting the management server.

- **ndb\_import CSV import tool.** `ndb_import`, added in NDB Cluster 7.6.2, loads CSV-formatted data directly into an `NDB` table using the NDB API (a MySQL server is needed only to create the table and database in which it is located). `ndb_import` can be regarded as an analog of `mysqldump`

or the `LOAD DATA` SQL statement, and supports many of the same or similar options for formatting of the data.

Assuming that the database and target `NDB` table exist, `ndb_import` needs only a connection to the cluster's management server (`ndb_mgmd`) to perform the importation; for this reason, there must be an `[api]` slot available to the tool in the cluster's `config.ini` file purpose.

See [Section 21.4.14, “`ndb\_import` — Import CSV Data Into NDB”](#), for more information.

- **`ndb_top` monitoring tool.** Added the `ndb_top` utility, which shows CPU load and usage information for an `NDB` data node in real time. This information can be displayed in text format, as an ASCII graph, or both. The graph can be shown in color, or using grayscale.

`ndb_top` connects to an NDB Cluster SQL node (that is, a MySQL Server). For this reason, the program must be able to connect as a MySQL user having the `SELECT` privilege on tables in the `ndbinfo` database.

`ndb_top` is available for Linux, Solaris, and macOS platforms beginning with NDB 7.6.3. It is not currently available for Windows platforms.

For more information, see [Section 21.4.30, “`ndb\_top` — View CPU usage information for NDB threads”](#).

- **Code cleanup.** A significant number of debugging statements and printouts not necessary for normal operations have been moved into code used only when testing or debugging `NDB`, or dispensed with altogether. This removal of overhead should result in a noticeable improvement in the performance of LDM and TC threads on the order of 10% in many cases.
- **LDM thread and LCP improvements.** Previously, when a local data management thread experienced I/O lag, it wrote to local checkpoints more slowly. This could happen, for example, during a disk overload condition. Problems could occur because other LDM threads did not always observe this state, or do likewise. `NDB` now tracks I/O lag mode globally, so that this state is reported as soon as at least one thread is writing in I/O lag mode; it then makes sure that the reduced write speed for this LCP is enforced for all LDM threads for the duration of the slowdown condition. Because the reduction in write speed is now observed by other LDM instances, overall capacity is increased; this enables the disk overload (or other condition inducing I/O lag) to be overcome more quickly in such cases than it was previously.
- **NDB error identification.** Error messages and information can be obtained using the `mysql` client in NDB 7.6.4 and later from a new `error_messages` table in the `ndbinfo` information database. In addition, the 7.6.4 release introduces a command-line client `ndb_perror` for obtaining information from NDB error codes; this replaces using `perror` with `--ndb`, which is now deprecated and subject to removal in a future release.

For more information, see [Section 21.5.14.21, “The `ndbinfo error\_messages` Table”](#), and [Section 21.4.17, “`ndb\_perror` — Obtain NDB Error Message Information”](#).

- **SPJ improvements.** When executing a scan as a pushed join (that is, the root of the query is a scan), the `DBTC` block sends an SPJ request to a `DBSPJ` instance on the same node as the fragment to be scanned. Formerly, one such request was sent for each of the node's fragments. As the number of `DBTC` and `DBSPJ` instances is normally set less than the number of LDM instances, this means that all SPJ instances were involved in the execution of a single query, and, in fact, some SPJ instances could (and did) receive multiple requests from the same query. In NDB 7.6.4, it becomes possible for a single SPJ request to handle a set of root fragments to be scanned, so that only a single SPJ request (`SCAN_FRAGREQ`) needs to be sent to any given SPJ instance (`DBSPJ` block) on each node.

Since `DBSPJ` consumes a relatively small amount of the total CPU used when evaluating a pushed join, unlike the LDM block (which is responsible for the majority of the CPU usage), introducing multiple SPJ blocks adds some parallelism, but the additional overhead also increases. By enabling

a single SPJ request to handle a set of root fragments to be scanned, such that only a single SPJ request is sent to each `DBSPJ` instance on each node and batch sizes are allocated per fragment, the multi-fragment scan can obtain a larger total batch size, allowing for some scheduling optimizations to be done within the SPJ block, which can scan a single fragment at a time (giving it the total batch size allocation), scan all fragments in parallel using smaller sub-batches, or some combination of the two.

This work is expected to increase performance of pushed-down joins for the following reasons:

- Since multiple root fragments can be scanned for each SPJ request, it is necessary to request fewer SPJ instances when executing a pushed join
- Increased available batch size allocation, and for each fragment, should also in most cases result in fewer requests being needed to complete a join
- **Improved O\_DIRECT handling for redo logs.** NDB 7.6.4 implements a new data node configuration parameter `ODirectSyncFlag` which causes completed redo log writes using `O_DIRECT` to be handled as `fsync` calls. `ODirectSyncFlag` is disabled by default; to enable it, set it to `true`.

You should bear in mind that the setting for this parameter is ignored when at least one of the following conditions is true:

- `ODirect` is not enabled.
- `InitFragmentLogFile`s is set to `SPARSE`.
- **Locking of CPUs to offline index build threads.** In NDB 7.6.4 and later, offline index builds by default use all cores available to `ndbmtd`, instead of being limited to the single core reserved for the I/O thread. It also becomes possible to specify a desired set of cores to be used for I/O threads performing offline multithreaded builds of ordered indexes. This can improve restart and restore times and performance, as well as availability.

#### Note

“Offline” as used here refers to an ordered index build that takes place while a given table is not being written to. Such index builds occur during a node or system restart, or when restoring a cluster from backup using `ndb_restore --rebuild-indexes`.

This improvement involves several related changes. The first of these is to change the default value for the `BuildIndexThreads` configuration parameter (from 0 to 128), means that offline ordered index builds are now multithreaded by default. The default value for the `TwoPassInitialNodeRestartCopy` is also changed (from `false` to `true`), so that an initial node restart first copies all data without any creation of indexes from a “live” node to the node which is being started, builds the ordered indexes offline after the data has been copied, then again synchronizes with the live node; this can significantly reduce the time required for building indexes. In addition, to facilitate explicit locking of offline index build threads to specific CPUs, a new thread type (`idxbld`) is defined for the `ThreadConfig` configuration parameter.

As part of this work, NDB can now distinguish between execution thread types and other types of threads, and between types of threads which are permanently assigned to specific tasks, and those whose assignments are merely temporary.

NDB 7.6.4 also introduces the `nosend` parameter for `ThreadConfig`. By setting this to 1, you can keep a `main`, `ldm`, `rep`, or `tc` thread from assisting the send threads. This parameter is 0 by default, and cannot be used with I/O threads, send threads, index build threads, or watchdog threads.

For additional information, see the descriptions of the parameters.

- **Variable batch sizes for DDL bulk data operations.** As part of work ongoing to optimize bulk DDL performance by `ndbmttd`, it is now possible to obtain performance improvements by increasing the batch size for the bulk data parts of DDL operations processing data using scans. Batch sizes are now made configurable for unique index builds, foreign key builds, and online reorganization, by setting the respective data node configuration parameters listed here:

- `MaxUIBuildBatchSize`: Maximum scan batch size used for building unique keys.
- `MaxFKBuildBatchSize`: Maximum scan batch size used for building foreign keys.
- `MaxReorgBuildBatchSize`: Maximum scan batch size used for reorganization of table partitions.

For each of the parameters just listed, the default value is 64, the minimum is 16, and the maximum is 512.

Increasing the appropriate batch size or sizes can help amortize inter-thread and inter-node latencies and make use of more parallel resources (local and remote) to help scale DDL performance. In each case there can be a tradeoff with ongoing traffic.

- **Partial LCPs.** NDB 7.6.4 implements partial local checkpoints. Formerly, an LCP always made a copy of the entire database. When working with terabytes of data this process could require a great deal of time, with an adverse impact on node and cluster restarts especially, as well as more space for the redo logs. It is now no longer strictly necessary for LCPs to do this—instead, an LCP now by default saves only a number of records that is based on the quantity of data changed since the previous LCP. This can vary between a full checkpoint and a checkpoint that changes nothing at all. In the event that the checkpoint reflects any changes, the minimum is to write one part of the 2048 making up a local LCP.

As part of this change, two new data node configuration parameters are introduced in this release: `EnablePartialLcp` (default `true`, or enabled) enables partial LCPs. `RecoveryWork` controls the percentage of space given over to LCPs; it increases with the amount of work which must be performed on LCPs during restarts as opposed to that performed during normal operations. Raising this value causes LCPs during normal operations to require writing fewer records and so decreases the usual workload. Raising this value also means that restarts can take longer.

You must disable partial LCPs explicitly by setting `EnablePartialLcp=false`. This uses the least amount of disk, but also tends to maximize the write load for LCPs. To optimize for the lowest workload on LCPs during normal operation, use `EnablePartialLcp=true` and `RecoveryWork=100`. To use the least disk space for partial LCPs, but with bounded writes, use `EnablePartialLcp=true` and `RecoveryWork=25`, which is the minimum for `RecoveryWork`. The default is `EnablePartialLcp=true` with `RecoveryWork=50`, which means LCP files require approximately 1.5 times `DataMemory`; using `CompressedLcp=1`, this can be further

reduced by half. Recovery times using the default settings should also be much faster than when `EnablePartialLcp` is set to `false`.

#### Note

The default value for `RecoveryWork` was increased from 50 to 60 in NDB 7.6.5.

In addition the data node configuration parameters `BackupDataBufferSize`, `BackupWriteSize`, and `BackupMaxWriteSize` are all now deprecated, and subject to removal in a future release of MySQL NDB Cluster.

As part of this enhancement, work has been done to correct several issues with node restarts wherein it was possible to run out of undo log in various situations, most often when restoring a node that had been down for a long time during a period of intensive write activity.

Additional work was done to improve data node survival of long periods of synchronization without timing out, by updating the LCP watchdog during this process, and keeping better track of the progress of disk data synchronization. Previously, there was the possibility of spurious warnings or even node failures if synchronization took longer than the LCP watchdog timeout.

#### Important

When upgrading an NDB Cluster that uses disk data tables to NDB 7.6.4 or downgrading it from NDB 7.6.4, it is necessary to restart all data nodes with `--initial`.

- **Parallel undo log record processing.** Formerly, the data node `LGMAN` kernel block processed undo log records serially; now this is done in parallel. The rep thread, which hands off undo records to LDM threads, waited for an LDM to finish applying a record before fetching the next one; now the rep thread no longer waits, but proceeds immediately to the next record and LDM.

A count of the number of outstanding log records for each LDM in `LGMAN` is kept, and decremented whenever an LDM has completed the execution of a record. All the records belonging to a page are sent to the same LDM thread but are not guaranteed to be processed in order, so a hash map of pages that have outstanding records maintains a queue for each of these pages. When the page is available in the page cache, all records pending in the queue are applied in order.

A few types of records continue to be processed serially: `UNDO_LCP`, `UNDO_LCP_FIRST`, `UNDO_LOCAL_LCP`, `UNDO_LOCAL_LCP_FIRST`, `UNDO_DROP`, and `UNDO_END`.

There are no user-visible changes in functionality directly associated with this performance enhancement; it is part of the work being done to improve undo long handling in support of partial local checkpoints in NDB Cluster 7.6.4.

- **Reading table and fragment IDs from extent for undo log applier.** When applying an undo log, it is necessary to obtain the table ID and fragment ID from the page ID. This was done previously by reading the page from the `PGMAN` kernel block using an extra `PGMAN` worker thread, but when applying the undo log it was necessary to read the page again.

when using `O_DIRECT` this was very inefficient since the page was not cached in the OS kernel. To correct this issue, mapping from page ID to table ID and fragment ID is now done using information from the extent header the table IDs and fragment IDs for the pages used within a given extent. The extent pages are always present in the page cache, so no extra reads from disk are required for performing the mapping. In addition, the information can already be read, using existing `TSMAN` kernel block data structures.

See the description of the `ODirect` data node configuration parameter, for more information.

- **Shared memory transporter.** User-defined shared memory (SHM) connections between a data node and an API node on the same host computer are supported in NDB 7.6.6 and later, and are no

longer considered experimental. You can enable an explicit shared memory connection by setting the `UseShm` configuration parameter to `1` for the relevant data node. When explicitly defining shared memory as the connection method, it is also necessary that both the data node and the API node are identified by `HostName`.

Performance of SHM connections can be enhanced through setting parameters such as `ShmSize`, `ShmSpintime`, and `SendBufferMemory` in an `[shm]` or `[shm default]` section of the cluster configuration file (`config.ini`). Configuration of SHM is otherwise similar to that of the TCP transporter.

The `SigNum` parameter is not used in the new SHM implementation, and any settings made for it are now ignored. [Section 21.3.3.12, “NDB Cluster Shared Memory Connections”](#), provides more information about these parameters. In addition, as part of this work, `NDB` code relating to the old SCI transporter has been removed.

For more information, see [Section 21.3.3.12, “NDB Cluster Shared Memory Connections”](#).

- **SPJ block inner join optimization.** In NDB 7.6.6 and later, the `SPJ` kernel block can take into account when it is evaluating a join request in which at least some of the tables are INNER-joined. This means that it can eliminate requests for row, ranges, or both as soon as it becomes known that one or more of the preceding requests did not return any results for a parent row. This saves both the data nodes and the `SPJ` block from having to handle requests and result rows which never take part in an INNER-joined result row.

Consider this join query, where `pk` is the primary key on tables `t2`, `t3`, and `t4`, and columns `x`, `y`, and `z` are nonindexed columns:

```
SELECT * FROM t1
JOIN t2 ON t2.pk = t1.x
JOIN t3 ON t3.pk = t1.y
JOIN t4 ON t4.pk = t1.z;
```

Previously, this resulted in an `SPJ` request including a scan on table `t1`, and lookups on each of the tables `t2`, `t3`, and `t4`; these were evaluated for every row returned from `t1`. For these, `SPJ` created `LQHKEYREQ` requests for tables `t2`, `t3`, and `t4`. Now `SPJ` takes into consideration the requirement that, to produce any result rows, an inner join must find a match in all tables joined; as soon as no matches are found for one of the tables, any further requests to tables having the same parent or tables are now skipped.

#### Note

This optimization cannot be applied until all of the data nodes and all of the API nodes in the cluster have been upgraded to NDB 7.6.6 or later.

- **NDB wakeup thread.** `NDB` uses a poll receiver to read from sockets, to execute messages from the sockets, and to wake up other threads. When making only intermittent use of a receive thread, poll ownership is given up before starting to wake up other threads, which provides some degree of parallelism in the receive thread, but, when making constant use of the receive thread, the thread can be overburdened by tasks including wakeup of other threads.

NDB 7.6.6 and later supports offloading by the receiver thread of the task of waking up other threads to a new thread that wakes up other threads on request (and otherwise simply sleeps), making it possible to improve the capacity of a single cluster connection by roughly ten to twenty percent.

- **Adaptive LCP control.** NDB 7.6.7 implements an adaptive LCP control mechanism which acts in response to changes in redo log space usage. By controlling LCP disk write speed, you can help protect against a number of resource-related issues, including the following:

- Insufficient CPU resources for traffic applications
- Disk overload
- Insufficient redo log buffer
- GCP Stop conditions
- Insufficient redo log space
- Insufficient undo log space

This work includes the following changes relating to [NDB](#) configuration parameters:

- The default value of the [RecoveryWork](#) data node parameter is increased from 50 to 60; that is, [NDB](#) now uses 1.6 times the size of the data for storage of LCPs.
- A new data node configuration parameter [InsertRecoveryWork](#) provides additional tuning capabilities through controlling the percentage of [RecoveryWork](#) that is reserved for insert operations. The default value is 40 (that is, 40% of the storage space already reserved by [RecoveryWork](#)); the minimum and maximum are 0 and 70, respectively. Increasing this value allows for more writes to be performed during an LCP, while limiting the total size of the LCP. Decreasing [InsertRecoveryWork](#) limits the number of writes used during an LCP, but results in more space being used for the LCP, which means that recovery takes longer.

This work implements control of LCP speed chiefly to minimize the risk of running out of redo log. This is done in adaptive fashion, based on the amount of redo log space used, using the alert levels, with the responses taken when these levels are attained, shown here:

- **Low:** Redo log space usage is greater than 25%, or estimated usage shows insufficient redo log space at a very high transaction rate. In response, use of LCP data buffers is increased during LCP scans, priority of LCP scans is increased, and the amount of data that can be written per real-time break in an LCP scan is also increased.
- **High:** Redo log space usage is greater than 40%, or estimate to run out of redo log space at a high transaction rate. When this level of usage is reached, [MaxDiskWriteSpeed](#) is increased to the value of [MaxDiskWriteSpeedOtherNodeRestart](#). In addition, the minimum speed is doubled, and priority of LCP scans and what can be written per real-time break are both increased further.
- **Critical:** Redo log space usage is greater than 60%, or estimated usage shows insufficient redo log space at a normal transaction rate. At this level, [MaxDiskWriteSpeed](#) is increased to the value of [MaxDiskWriteSpeedOwnRestart](#); [MinDiskWriteSpeed](#) is also set to this value. Priority of LCP scans and the amount of data that can be written per real-time break are increased further, and the LCP data buffer is completely available during the LCP scan.

Raising the level also has the effect of increasing the calculated target checkpoint speed.

LCP control has the following benefits for [NDB](#) installations:

- Clusters should now survive very heavy loads using default configurations much better than previously.
- It should now be possible for [NDB](#) to run reliably on systems where the available disk space is (at a rough minimum) 2.1 times the amount of memory allocated to it ([DataMemory](#)). You should note that this figure does *not* include any disk space used for Disk Data tables.

- **ndb\_restore options.** Beginning with NDB 7.6.9, the `--nodeid` and `--backupid` options are both required when invoking `ndb_restore`.
- **Restoring by slices.** Beginning with NDB 7.6.13, it is possible to divide a backup into roughly equal portions (slices) and to restore these slices in parallel using two new options implemented for `ndb_restore`:
  - `--num-slices` determines the number of slices into which the backup should be divided.
  - `--slice-id` provides the ID of the slice to be restored by the current instance of `ndb_restore`.

This makes it possible to employ multiple instances of `ndb_restore` to restore subsets of the backup in parallel, potentially reducing the amount of time required to perform the restore operation.

For more information, see the description of the `ndb_restore --num-slices` option.

- **ndb\_restore: primary key schema changes.** NDB 7.6.14 (and later) supports different primary key definitions for source and target tables when restoring an NDB native backup with `ndb_restore` when it is run with the `--allow-pk-changes` option. Both increasing and decreasing the number of columns making up the original primary key are supported.

When the primary key is extended with an additional column or columns, any columns added must be defined as `NOT NULL`, and no values in any such columns may be changed during the time that the backup is being taken. Because some applications set all column values in a row when updating it, whether or not all values are actually changed, this can cause a restore operation to fail even if no values in the column to be added to the primary key have changed. You can override this behavior using the `--ignore-extended-pk-updates` option also added in NDB 7.6.14; in this case, you must ensure that no such values are changed.

A column can be removed from the table's primary key whether or not this column remains part of the table.

For more information, see the description of the `--allow-pk-changes` option for `ndb_restore`.

- **ndb\_blob\_tool enhancements.** Beginning with NDB 7.6.14, the `ndb_blob_tool` utility can detect missing blob parts for which inline parts exist and replace these with placeholder blob parts (consisting of space characters) of the correct length. To check whether there are missing blob parts, use the `--check-missing` option with this program. To replace any missing blob parts with placeholders, use the `--add-missing` option.

For more information, see [Section 21.4.6, “ndb\\_blob\\_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables”](#).

- **Merging backups with ndb\_restore.** In some cases, it may be desirable to consolidate data originally stored in different instances of NDB Cluster (all using the same schema) into a single target NDB Cluster. This is now supported when using backups created in the `ndb_mgm` client (see [Section 21.5.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#)) and restoring them with `ndb_restore`, using the `--remap-column` option added in NDB 7.6.14 along with `--restore-data` (and possibly additional compatible options as needed or desired). `--remap-column` can be employed to handle cases in which primary and unique key values are overlapping between source clusters, and it is necessary that they do not overlap in the target cluster, as well as to preserve other relationships between tables such as foreign keys.

`--remap-column` takes as its argument a string having the format `db.tbl.col:fn:args`, where `db`, `tbl`, and `col` are, respectively, the names of the database, table, and column, `fn` is the name of a remapping function, and `args` is one or more arguments to `fn`. There is no default value. Only `offset` is supported as the function name, with `args` as the integer offset to be applied to the value of the column when inserting it into the target table from the backup. This column must be one of `INT`

or `BIGINT`; the allowed range of the offset value is the same as the signed version of that type (this allows the offset to be negative if desired).

The new option can be used multiple times in the same invocation of `ndb_restore`, so that you can remap to new values multiple columns of the same table, different tables, or both. The offset value does not have to be the same for all instances of the option.

In addition, two new options are provided for `ndb_desc`, also beginning in NDB 7.6.14:

- `--auto-inc` (short form `-a`): Includes the next auto-increment value in the output, if the table has an `AUTO_INCREMENT` column.
- `--context` (short form `-x`): Provides extra information about the table, including the schema, database name, table name, and internal ID.

For more information and examples, see the description of the `--remap-column` option.

- **--ndb-log-fail-terminate option.** Beginning with NDB 7.6.14, you can cause the SQL node to terminate whenever it is unable to log all row events fully. This can be done by starting `mysqld` with the `--ndb-log-fail-terminate` option.
- **NDB programs—NDBT dependency removal.** The dependency of a number of `NDB` utility programs on the `NDBT` library has been removed. This library is used internally for development, and is not required for normal use; its inclusion in these programs could lead to unwanted issues when testing.

Affected programs are listed here, along with the `NDB` versions in which the dependency was removed:

- `ndb_restore`, in NDB 7.6.11
- `ndb_show_tables`, in NDB 7.6.14
- `ndb_waiter`, in NDB 7.6.14

The principal effect of this change for users is that these programs no longer print `NDBT_ProgramExit - status` following completion of a run. Applications that depend upon such behavior should be updated to reflect the change when upgrading to the indicated versions.

- **Auto-Installer deprecation and removal.** The MySQL NDB Cluster Auto-Installer web-based installation tool (`ndb_setup.py`) is deprecated in NDB 7.6.16, and is removed in NDB 7.6.17 and later. It is no longer supported.
- **ndbmemcache deprecation and removal.** `ndbmemcache` is no longer supported. `ndbmemcache` was deprecated in NDB 7.6.16, and removed in NDB 7.6.17.
- **Node.js support removed.** Beginning with the NDB Cluster 7.6.16 release, support for Node.js by NDB 7.6 has been removed.

Support for Node.js by NDB Cluster is maintained in NDB 8.0 only.

- **Conversion between NULL and NOT NULL during restore operations.** Beginning with NDB 7.6.19, `ndb_restore` can support restoring of `NULL` columns as `NOT NULL` and the reverse, using the options listed here:
    - To restore a `NULL` column as `NOT NULL`, use the `--lossy-conversions` option.  
The column originally declared as `NULL` must not contain any `NULL` rows; if it does, `ndb_restore` exits with an error.
    - To restore a `NOT NULL` column as `NULL`, use the `--promote-attributes` option.
- For more information, see the descriptions of the indicated `ndb_restore` options.

## 21.1.5 NDB: Added, Deprecated, and Removed Options, Variables, and Parameters

### 21.1.5.1 Options, Variables, and Parameters Added, Deprecated or Removed in NDB 7.5

- [Parameters Introduced in NDB 7.5](#)
- [Parameters Deprecated in NDB 7.5](#)
- [Parameters Removed in NDB 7.5](#)
- [Options and Variables Introduced in NDB 7.5](#)
- [Options and Variables Deprecated in NDB 7.5](#)
- [Options and Variables Removed in NDB 7.5](#)

The next few sections contain information about NDB node configuration parameters and NDB-specific `mysqld` options and variables that have been added to, deprecated in, or removed from NDB 7.5.

#### Parameters Introduced in NDB 7.5

The following node configuration parameters have been added in NDB 7.5.

- `ApiVerbose`: Enable NDB API debugging; for NDB development. Added in NDB 7.5.2.

#### Parameters Deprecated in NDB 7.5

The following node configuration parameters have been deprecated in NDB 7.5.

- `ExecuteOnComputer`: String referencing earlier defined COMPUTER. Deprecated in NDB 7.5.0.
- `ExecuteOnComputer`: String referencing earlier defined COMPUTER. Deprecated in NDB 7.5.0.
- `ExecuteOnComputer`: String referencing earlier defined COMPUTER. Deprecated in NDB 7.5.0.

#### Parameters Removed in NDB 7.5

The following node configuration parameters have been removed in NDB 7.5.

- `DiskCheckpointSpeed`: Bytes allowed to be written by checkpoint, per second. Removed in NDB 7.5.0.
- `DiskCheckpointSpeedInRestart`: Bytes allowed to be written by checkpoint during restart, per second. Removed in NDB 7.5.0.
- `Id`: Number identifying data node. Now deprecated; use `Nodeld` instead. Removed in NDB 7.5.0.

- [MaxNoOfSavedEvents](#): Not used. Removed in NDB 7.5.0.
- [PortNumber](#): Port used for SCI transporter. Removed in NDB 7.5.1.
- [PortNumber](#): Port used for SHM transporter. Removed in NDB 7.5.1.
- [PortNumber](#): Port used for TCP transporter. Removed in NDB 7.5.1.
- [ReservedSendBufferMemory](#): This parameter is present in NDB code but is not enabled. Removed in NDB 7.5.2.

## Options and Variables Introduced in NDB 7.5

The following system variables, status variables, and server options have been added in NDB 7.5.

- [Ndb\\_system\\_name](#): Configured cluster system name; empty if server not connected to NDB. Added in NDB 7.5.7.
- [ndb-allow-copying-alter-table](#): Set to OFF to keep ALTER TABLE from using copying operations on NDB tables. Added in NDB 7.5.0.
- [ndb-cluster-connection-pool-nodeids](#): Comma-separated list of node IDs for connections to cluster used by MySQL; number of nodes in list must match value set for --ndb-cluster-connection-pool. Added in NDB 7.5.0.
- [ndb-default-column-format](#): Use this value (FIXED or DYNAMIC) by default for COLUMN\_FORMAT and ROW\_FORMAT options when creating or adding table columns. Added in NDB 7.5.1.
- [ndb-log-fail-terminate](#): Terminate mysqld process if complete logging of all found row events is not possible. Added in NDB 7.5.18.
- [ndb-log-update-minimal](#): Log updates in minimal format. Added in NDB 7.5.7.
- [ndb\\_data\\_node\\_neighbour](#): Specifies cluster data node "closest" to this MySQL Server, for transaction hinting and fully replicated tables. Added in NDB 7.5.2.
- [ndb\\_default\\_column\\_format](#): Sets default row format and column format (FIXED or DYNAMIC) used for new NDB tables. Added in NDB 7.5.1.
- [ndb\\_read\\_backup](#): Enable read from any replica for all NDB tables; use NDB\_TABLE=READ\_BACKUP={0|1} with CREATE TABLE or ALTER TABLE to enable or disable for individual NDB tables. Added in NDB 7.5.2.

## Options and Variables Deprecated in NDB 7.5

No system variables, status variables, or server options have been deprecated in NDB 7.5.

## Options and Variables Removed in NDB 7.5

No system variables, status variables, or options have been removed in NDB 7.5.

### 21.1.5.2 Options, Variables, and Parameters Added, Deprecated or Removed in NDB 7.6

- [Parameters Introduced in NDB 7.6](#)
- [Parameters Deprecated in NDB 7.6](#)
- [Parameters Removed in NDB 7.6](#)
- [Options and Variables Introduced in NDB 7.6](#)

- [Options and Variables Deprecated in NDB 7.6](#)
- [Options and Variables Removed in NDB 7.6](#)

The next few sections contain information about [NDB](#) node configuration parameters and NDB-specific [mysqld](#) options and variables that have been added to, deprecated in, or removed from NDB 7.6.

## Parameters Introduced in NDB 7.6

The following node configuration parameters have been added in NDB 7.6.

- [EnablePartialLcp](#): Enable partial LCP (true); if this is disabled (false), all LCPs write full checkpoints. Added in NDB 7.6.4.
- [Enableredocontrol](#): Enable adaptive checkpointing speed for controlling redo log usage. Added in NDB 7.6.7.
- [InsertRecoveryWork](#): Percentage of RecoveryWork used for inserted rows; has no effect unless partial local checkpoints are in use. Added in NDB 7.6.5.
- [LocationDomainId](#): Assign this API node to specific availability domain or zone. 0 (default) leaves this unset. Added in NDB 7.6.4.
- [LocationDomainId](#): Assign this management node to specific availability domain or zone. 0 (default) leaves this unset. Added in NDB 7.6.4.
- [LocationDomainId](#): Assign this data node to specific availability domain or zone. 0 (default) leaves this unset. Added in NDB 7.6.4.
- [MaxFKBuildBatchSize](#): Maximum scan batch size to use for building foreign keys. Increasing this value may speed up builds of foreign keys but impacts ongoing traffic as well. Added in NDB 7.6.4.
- [MaxReorgBuildBatchSize](#): Maximum scan batch size to use for reorganization of table partitions. Increasing this value may speed up table partition reorganization but impacts ongoing traffic as well. Added in NDB 7.6.4.
- [MaxUIBuildBatchSize](#): Maximum scan batch size to use for building unique keys. Increasing this value may speed up builds of unique keys but impacts ongoing traffic as well. Added in NDB 7.6.4.
- [ODirectSyncFlag](#): O\_DIRECT writes are treated as synchronized writes; ignored when ODIRECT is not enabled, InitFragmentLogFiles is set to SPARSE, or both. Added in NDB 7.6.4.
- [PreSendChecksum](#): If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors. Added in NDB 7.6.6.
- [PreSendChecksum](#): If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors. Added in NDB 7.6.6.
- [RecoveryWork](#): Percentage of storage overhead for LCP files: greater value means less work in normal operations, more work during recovery. Added in NDB 7.6.4.
- [SendBufferMemory](#): Bytes in shared memory buffer for signals sent from this node. Added in NDB 7.6.6.
- [ShmSpinTime](#): When receiving, number of microseconds to spin before sleeping. Added in NDB 7.6.6.
- [UseShm](#): Use shared memory connections between this data node and API node also running on this host. Added in NDB 7.6.6.
- [WatchDogImmediateKill](#): When true, threads are immediately killed whenever watchdog issues occur; used for testing and debugging. Added in NDB 7.6.7.

## Parameters Deprecated in NDB 7.6

The following node configuration parameters have been deprecated in NDB 7.6.

- [BackupDataBufferSize](#): Default size of databuffer for backup (in bytes). Deprecated in NDB 7.6.4.
- [BackupMaxWriteSize](#): Maximum size of file system writes made by backup (in bytes). Deprecated in NDB 7.6.4.
- [BackupWriteSize](#): Default size of file system writes made by backup (in bytes). Deprecated in NDB 7.6.4.
- [IndexMemory](#): Number of bytes on each data node allocated for storing indexes; subject to available system RAM and size of DataMemory. Deprecated in NDB 7.6.2.
- [Signum](#): Signal number to be used for signalling. Deprecated in NDB 7.6.6.

## Parameters Removed in NDB 7.6

No node configuration parameters have been removed in NDB 7.6.

## Options and Variables Introduced in NDB 7.6

The following system variables, status variables, and server options have been added in NDB 7.6.

- [Ndb\\_system\\_name](#): Configured cluster system name; empty if server not connected to NDB. Added in NDB 7.6.2.
- [ndb-log-fail-terminate](#): Terminate mysqld process if complete logging of all found row events is not possible. Added in NDB 7.6.14.
- [ndb-log-update-minimal](#): Log updates in minimal format. Added in NDB 7.6.3.
- [ndb\\_row\\_checksum](#): When enabled, set row checksums; enabled by default. Added in NDB 7.6.8.

## Options and Variables Deprecated in NDB 7.6

No system variables, status variables, or server options have been deprecated in NDB 7.6.

## Options and Variables Removed in NDB 7.6

No system variables, status variables, or options have been removed in NDB 7.6.

## 21.1.6 MySQL Server Using InnoDB Compared with NDB Cluster

MySQL Server offers a number of choices in storage engines. Since both [NDB](#) and [InnoDB](#) can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in NDB Cluster. They see [NDB](#) as a possible alternative or upgrade to the default [InnoDB](#) storage engine in MySQL 5.7. While [NDB](#) and [InnoDB](#) share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for NDB Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the [NDB](#) storage engine used by NDB 7.5 with [InnoDB](#) used in MySQL 5.7. The next few sections provide a technical comparison. In many instances, decisions about when and where to use NDB Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for [NDB](#) as opposed to [InnoDB](#) backends.

NDB Cluster 7.5 uses a `mysqld` based on MySQL 5.7, including support for [InnoDB](#) 1.1. While it is possible to use [InnoDB](#) tables with NDB Cluster, such tables are not clustered. It is also not possible to use programs or libraries from an NDB Cluster 7.5 distribution with MySQL Server 5.7, or the reverse.

While it is also true that some types of common business applications can be run either on NDB Cluster or on MySQL Server (most likely using the [InnoDB](#) storage engine), there are some important architectural and implementation differences. [Section 21.1.6.1, “Differences Between the NDB and InnoDB Storage Engines”](#), provides a summary of the these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see [Section 21.1.6.2, “NDB and InnoDB Workloads”](#). This in turn has an impact on the types of applications that better suited for use with [NDB](#) or [InnoDB](#). See [Section 21.1.6.3, “NDB and InnoDB Feature Usage Summary”](#), for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the [NDB](#) and [MEMORY](#) storage engines, see [When to Use MEMORY or NDB Cluster](#).

See [Chapter 15, Alternative Storage Engines](#), for additional information about MySQL storage engines.

## 21.1.6.1 Differences Between the NDB and InnoDB Storage Engines

The [NDB](#) storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from [InnoDB](#) in a number of ways. For those unaccustomed to working with [NDB](#), unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, table limits, and other characteristics. These are shown in the following table:

**Table 21.1 Differences between InnoDB and NDB storage engines**

| Feature                       | InnoDB (MySQL 5.7)                                                                                                          | NDB 7.5/7.6                                                                                                                                                                    |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MySQL Server Version          | 5.7                                                                                                                         | 5.7                                                                                                                                                                            |
| InnoDB Version                | InnoDB 5.7.34                                                                                                               | InnoDB 5.7.34                                                                                                                                                                  |
| NDB Cluster Version           | N/A                                                                                                                         | NDB 7.5.23/7.6.19                                                                                                                                                              |
| Storage Limits                | 64TB                                                                                                                        | 128TB (as of NDB 7.5.2)                                                                                                                                                        |
| Foreign Keys                  | Yes                                                                                                                         | Yes                                                                                                                                                                            |
| Transactions                  | All standard types                                                                                                          | READ COMMITTED                                                                                                                                                                 |
| MVCC                          | Yes                                                                                                                         | No                                                                                                                                                                             |
| Data Compression              | Yes                                                                                                                         | No (NDB checkpoint and backup files can be compressed)                                                                                                                         |
| Large Row Support (> 14K)     | Supported for <a href="#">VARBINARY</a> , <a href="#">VARCHAR</a> , <a href="#">BLOB</a> , and <a href="#">TEXT</a> columns | Supported for <a href="#">BLOB</a> and <a href="#">TEXT</a> columns only (Using these types to store very large amounts of data can lower NDB performance)                     |
| Replication Support           | Asynchronous and semisynchronous replication using MySQL Replication; MySQL <a href="#">Group Replication</a>               | Automatic synchronous replication within an NDB Cluster; asynchronous replication between NDB Clusters, using MySQL Replication (Semisynchronous replication is not supported) |
| Scaleout for Read Operations  | Yes (MySQL Replication)                                                                                                     | Yes (Automatic partitioning in NDB Cluster; NDB Cluster Replication)                                                                                                           |
| Scaleout for Write Operations | Requires application-level partitioning (sharding)                                                                          | Yes (Automatic partitioning in NDB Cluster is transparent to applications)                                                                                                     |

| Feature                                                          | InnoDB (MySQL 5.7)                                | NDB 7.5/7.6                                                                                        |
|------------------------------------------------------------------|---------------------------------------------------|----------------------------------------------------------------------------------------------------|
| High Availability (HA)                                           | Built-in, from InnoDB cluster                     | Yes (Designed for 99.999% uptime)                                                                  |
| Node Failure Recovery and Failover                               | From MySQL Group Replication                      | Automatic (Key element in NDB architecture)                                                        |
| Time for Node Failure Recovery                                   | 30 seconds or longer                              | Typically < 1 second                                                                               |
| Real-Time Performance                                            | No                                                | Yes                                                                                                |
| In-Memory Tables                                                 | No                                                | Yes (Some data can optionally be stored on disk; both in-memory and disk data storage are durable) |
| NoSQL Access to Storage Engine                                   | Yes                                               | Yes (Multiple APIs, including Memcached, Node.js/JavaScript, Java, JPA, C++, and HTTP/REST)        |
| Concurrent and Parallel Writes                                   | Yes                                               | Up to 48 writers, optimized for concurrent writes                                                  |
| Conflict Detection and Resolution (Multiple Replication Sources) | Yes (MySQL Group Replication)                     | Yes                                                                                                |
| Hash Indexes                                                     | No                                                | Yes                                                                                                |
| Online Addition of Nodes                                         | Read/write replicas using MySQL Group Replication | Yes (all node types)                                                                               |
| Online Upgrades                                                  | Yes (using replication)                           | Yes                                                                                                |
| Online Schema Modifications                                      | Yes, as part of MySQL 5.7                         | Yes                                                                                                |

### 21.1.6.2 NDB and InnoDB Workloads

NDB Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, NDB Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the NDB and InnoDB storage engines with regard to some common types of database-driven application workloads are shown in the following table::

**Table 21.2 Differences between InnoDB and NDB storage engines, common types of data-driven application workloads.**

| Workload                                         | InnoDB | NDB Cluster (NDB)                                                                    |
|--------------------------------------------------|--------|--------------------------------------------------------------------------------------|
| High-Volume OLTP Applications                    | Yes    | Yes                                                                                  |
| DSS Applications (data marts, analytics)         | Yes    | Limited (Join operations across OLTP datasets not exceeding 3TB in size)             |
| Custom Applications                              | Yes    | Yes                                                                                  |
| Packaged Applications                            | Yes    | Limited (should be mostly primary key access); NDB Cluster 7.5 supports foreign keys |
| In-Network Telecoms Applications (HLR, HSS, SDP) | No     | Yes                                                                                  |
| Session Management and Caching                   | Yes    | Yes                                                                                  |

| Workload                              | InnoDB | NDB Cluster (NDB) |
|---------------------------------------|--------|-------------------|
| E-Commerce Applications               | Yes    | Yes               |
| User Profile Management, AAA Protocol | Yes    | Yes               |

### 21.1.6.3 NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of InnoDB with NDB, some are clearly more compatible with one storage engine than the other.

The following table lists supported application features according to the storage engine to which each feature is typically better suited.

**Table 21.3 Supported application features according to the storage engine to which each feature is typically better suited**

| Preferred application requirements for InnoDB                                                                                                                                                                                                                                                                                                                                                      | Preferred application requirements for NDB                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### 21.1.7 Known Limitations of NDB Cluster

In the sections that follow, we discuss known limitations in current releases of NDB Cluster as compared with the features available when using the MyISAM and InnoDB storage engines. If you check the “Cluster” category in the MySQL bugs database at <http://bugs.mysql.com>, you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at <http://bugs.mysql.com>, which we intend to correct in upcoming releases of NDB Cluster:

- NDB Cluster
- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication
- ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). Any problem which we do not plan to fix in NDB Cluster 7.5 is added to the list.

See [Previous NDB Cluster Issues Resolved in NDB Cluster 8.0](#) for a list of issues in earlier releases that have been resolved in NDB Cluster 7.5.

**Note**

Limitations and other issues specific to NDB Cluster Replication are described in [Section 21.6.3, “Known Issues in NDB Cluster Replication”](#).

### 21.1.7.1 Noncompliance with SQL Syntax in NDB Cluster

Some SQL statements relating to certain MySQL features produce errors when used with `NDB` tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the `NDB` storage engine or to alter an existing temporary table to use `NDB` fails with the error `Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'`.
- **Indexes and keys in NDB tables.** Keys and indexes on NDB Cluster tables are subject to the following limitations:
  - **Column width.** Attempting to create an index on an `NDB` table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `Specified key was too long; max key length is 3072 bytes` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.
  - **TEXT and BLOB columns.** You cannot create indexes on `NDB` table columns that use any of the `TEXT` or `BLOB` data types.
  - **FULLTEXT indexes.** The `NDB` storage engine does not support `FULLTEXT` indexes, which are possible for `MyISAM` and `InnoDB` tables only.

However, you can create indexes on `VARCHAR` columns of `NDB` tables.

- **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column `NOT NULL`, or re-create the index without the `USING HASH` option.
- **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an `NDB` column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see [Section 21.1.7.6, “Unsupported or Missing Features in NDB Cluster”](#), for additional information.)
- **BIT columns.** A `BIT` column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
- **AUTO\_INCREMENT columns.** Like other MySQL storage engines, the `NDB` storage engine can handle a maximum of one `AUTO_INCREMENT` column per table. However, in the case of an NDB table with no explicit primary key, an `AUTO_INCREMENT` column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit `AUTO_INCREMENT` column unless that column is also declared using the `PRIMARY KEY` option. Attempting to create a table with an `AUTO_INCREMENT` column that is not the table’s primary key, and using the `NDB` storage engine, fails with an error.
- **Restrictions on foreign keys.** Support for foreign key constraints in NDB 7.5 is comparable to that provided by `InnoDB`, subject to the following restrictions:
  - Every column referenced as a foreign key requires an explicit unique key, if it is not the table’s primary key.
  - `ON UPDATE CASCADE` is not supported when the reference is to the parent table’s primary key.

This is because an update of a primary key is implemented as a delete of the old row (containing the old primary key) plus an insert of the new row (with a new primary key). This is not visible to

the `NDB` kernel, which views these two rows as being the same, and thus has no way of knowing that this update should be cascaded.

- As of NDB 7.5.14 and NDB 7.6.10: `ON DELETE CASCADE` is not supported where the child table contains one or more columns of any of the `TEXT` or `BLOB` types. (Bug #89511, Bug #27484882)
- `SET DEFAULT` is not supported. (Also not supported by `InnoDB`.)
- The `NO ACTION` keywords are accepted but treated as `RESTRICT`. (Also the same as with `InnoDB`.)
- In earlier versions of NDB Cluster, when creating a table with foreign key referencing an index in another table, it sometimes appeared possible to create the foreign key even if the order of the columns in the indexes did not match, due to the fact that an appropriate error was not always returned internally. A partial fix for this issue improved the error used internally to work in most cases; however, it remains possible for this situation to occur in the event that the parent index is a unique index. (Bug #18094360)
- Prior to NDB 7.5.6, when adding or dropping a foreign key using `ALTER TABLE`, the parent table's metadata is not updated, which makes it possible subsequently to execute `ALTER TABLE` statements on the parent that should be invalid. To work around this issue, execute `SHOW CREATE TABLE` on the parent table immediately after adding or dropping the foreign key; this forces the parent's metadata to be reloaded.

This issue is fixed in NDB 7.5.6. (Bug #82989, Bug #24666177)

For more information, see [Section 13.1.18.5, “FOREIGN KEY Constraints”](#), and [Section 1.7.3.2, “FOREIGN KEY Constraints”](#).

- **NDB Cluster and geometry data types.** Geometry data types (`WKT` and `WKB`) are supported for `NDB` tables. However, spatial indexes are not supported.
- **Character sets and binary log files.** Currently, the `ndb_apply_status` and `ndb_binlog_index` tables are created using the `latin1` (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

To work around this problem, use only Latin-1 characters when naming binary log files or setting any the `--basedir`, `--log-bin`, or `--log-bin-index` options.

- **Creating NDB tables with user-defined partitioning.** Support for user-defined partitioning in NDB Cluster is restricted to `[LINEAR] KEY` partitioning. Using any other partitioning type with `ENGINE=NDB` or `ENGINE=NDCLUSTER` in a `CREATE TABLE` statement results in an error.

It is possible to override this restriction, but doing so is not supported for use in production settings. For details, see [User-defined partitioning and the NDB storage engine \(NDB Cluster\)](#).

**Default partitioning scheme.** All NDB Cluster tables are by default partitioned by `KEY` using the table's primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the `NDB` storage engine is used instead. For additional discussion of these and related issues, see [Section 22.2.5, “KEY Partitioning”](#).

`CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDCLUSTER` table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

**Exception.** If a user-partitioned `NDBCLUSTER` table is created using an empty column-list (that is, using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

**Maximum number of partitions for NDBCLUSTER tables.** The maximum number of partitions that can be defined for a `NDBCLUSTER` table when employing user-defined partitioning is 8 per node group. (See [Section 21.1.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#), for more information about NDB Cluster node groups.)

**DROP PARTITION not supported.** It is not possible to drop partitions from `NDB` tables using `ALTER TABLE ... DROP PARTITION`. The other partitioning extensions to `ALTER TABLE—ADD PARTITION, REORGANIZE PARTITION, and COALESCE PARTITION`—are supported for NDB tables, but use copying and so are not optimized. See [Section 22.3.1, “Management of RANGE and LIST Partitions”](#) and [Section 13.1.8, “ALTER TABLE Statement”](#).

- **JSON data type.** The MySQL `JSON` data type is supported for `NDB` tables in the `mysqld` supplied with NDB 7.5.2 and later.

An `NDB` table can have a maximum of 3 `JSON` columns.

The NDB API has no special provision for working with `JSON` data, which it views simply as `BLOB` data. Handling data as `JSON` must be performed by the application.

- **CPU and thread info ndbinfo tables.** NDB 7.5.2 adds several new tables to the `ndbinfo` information database providing information about CPU and thread activity by node, thread ID, and thread type. The tables are listed here:

- `cpustat`: Provides per-second, per-thread CPU statistics
- `cpustat_50ms`: Raw per-thread CPU statistics data, gathered every 50ms
- `cpustat_1sec`: Raw per-thread CPU statistics data, gathered each second
- `cpustat_20sec`: Raw per-thread CPU statistics data, gathered every 20 seconds
- `threads`: Names and descriptions of thread types

For more information about these tables, see [Section 21.5.14, “ndbinfo: The NDB Cluster Information Database”](#).

- **Lock info ndbinfo tables.** NDB 7.5.3 adds new tables to the `ndbinfo` information database providing information about locks and lock attempts in a running NDB Cluster. These tables are listed here:

- `cluster_locks`: Current lock requests which are waiting for or holding locks; this information can be useful when investigating stalls and deadlocks. Analogous to `cluster_operations`.
- `locks_per_fragment`: Counts of lock claim requests, and their outcomes per fragment, as well as total time spent waiting for locks successfully and unsuccessfully. Analogous to `operations_per_fragment` and `memory_per_fragment`.
- `server_locks`: Subset of cluster transactions—those running on the local `mysqld`, showing a connection id per transaction. Analogous to `server_operations`.

## 21.1.7.2 Limits and Differences of NDB Cluster from Standard MySQL Limits

In this section, we list limits found in NDB Cluster that either differ from limits found in, or that are not found in, standard MySQL.

**Memory usage and recovery.** Memory consumed when data is inserted into an `NDB` table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A `DELETE` statement on an `NDB` table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing `OPTIMIZE TABLE`.

A rolling restart of the cluster also frees any memory used by deleted rows. See [Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”](#).

- A `DROP TABLE` or `TRUNCATE TABLE` operation on an `NDB` table frees the memory that was used by this table for re-use by any `NDB` table, either by the same table or by another `NDB` table.

#### Note

Recall that `TRUNCATE TABLE` drops and re-creates the table. See [Section 13.1.34, “`TRUNCATE TABLE` Statement”](#).

- **Limits imposed by the cluster's configuration.**

A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in [Section 21.3.3, “NDB Cluster Configuration Files”](#). Most configuration parameters can be upgraded online. These hard limits include:

- Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).

`DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

See [Section 21.3.3.6, “Defining NDB Cluster Data Nodes”](#), for more information.

- The maximum number of operations that can be performed per transaction is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`.

#### Note

Bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.

- Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by `MaxNoOfOrderedIndexes`, and the maximum number of ordered indexes per table is 16.

- **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:

- The maximum number of data nodes is 48.

A data node must have a node ID in the range of 1 to 48, inclusive. (Management and API nodes may use node IDs in the range 1 to 255, inclusive.)

- The total maximum number of nodes in an NDB Cluster is 255. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.
- The maximum number of metadata objects in current versions of NDB Cluster is 20320. This limit is hard-coded.

See [Previous NDB Cluster Issues Resolved in NDB Cluster 8.0](#), for more information.

### 21.1.7.3 Limits Relating to Transaction Handling in NDB Cluster

A number of limitations exist in NDB Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. (`InnoDB`, for example, supports `READ COMMITTED`, `READ UNCOMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.) You should keep in mind that `NDB` implements `READ COMMITTED` on a per-row basis; when a read request arrives at the data node storing the row, what is returned is the last committed version of the row at that time.

Uncommitted data is never returned, but when a transaction modifying a number of rows commits concurrently with a transaction reading the same rows, the transaction performing the read can observe “before” values, “after” values, or both, for different rows among these, due to the fact that a given row read request can be processed either before or after the commit of the other transaction.

To ensure that a given transaction reads only before or after values, you can impose row locks using `SELECT ... LOCK IN SHARE MODE`. In such cases, the lock is held until the owning transaction is committed. Using row locks can also cause the following issues:

- Increased frequency of lock wait timeout errors, and reduced concurrency
- Increased transaction processing overhead due to reads requiring a commit phase
- Possibility of exhausting the available number of concurrent locks, which is limited by `MaxNoOfConcurrentOperations`

`NDB` uses `READ COMMITTED` for all reads unless a modifier such as `LOCK IN SHARE MODE` or `FOR UPDATE` is used. `LOCK IN SHARE MODE` causes shared row locks to be used; `FOR UPDATE` causes exclusive row locks to be used. Unique key reads have their locks upgraded automatically by `NDB` to ensure a self-consistent read; `BLOB` reads also employ extra locking for consistency.

See [Section 21.5.8.4, “NDB Cluster Backup Troubleshooting”](#), for information on how `NDB Cluster`'s implementation of transaction isolation level can affect backup and restoration of `NDB` databases.

- **Transactions and BLOB or TEXT columns.** `NDBCLUSTER` stores only part of a column value that uses any of MySQL's `BLOB` or `TEXT` data types in the table visible to MySQL; the remainder of the `BLOB` or `TEXT` is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing `SELECT` statements on tables that contain columns of these types:

1. For any `SELECT` from an `NDB Cluster` table: If the `SELECT` includes a `BLOB` or `TEXT` column, the `READ COMMITTED` transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.
2. For any `SELECT` which uses a unique key lookup to retrieve any columns that use any of the `BLOB` or `TEXT` data types and that is executed within a transaction, a shared read lock is held on the table for the duration of the transaction—that is, until the transaction is either committed or aborted.

This issue does not occur for queries that use index or table scans, even against `NDB` tables having `BLOB` or `TEXT` columns.

For example, consider the table `t` defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (
 a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 b INT NOT NULL,
 c INT NOT NULL,
 d TEXT,
 INDEX i(b),
 UNIQUE KEY u(c)
```

```
) ENGINE = NDB,
```

The following query on `t` causes a shared read lock, because it uses a unique key lookup:

```
SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```
SELECT * FROM t WHERE b = 1;
SELECT * FROM t WHERE d = '1';
SELECT * FROM t;
SELECT b,c WHERE a = 1;
```

This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any `BLOB` or `TEXT` columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups that retrieve `BLOB` or `TEXT` columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Unique key lookups and transaction isolation.** Unique indexes are implemented in `NDB` using a hidden index table which is maintained internally. When a user-created `NDB` table is accessed using a unique index, the hidden index table is first read to find the primary key that is then used to read the user-created table. To avoid modification of the index during this double-read operation, the row found in the hidden index table is locked. When a row referenced by a unique index in the user-created `NDB` table is updated, the hidden index table is subject to an exclusive lock by the transaction in which the update is performed. This means that any read operation on the same (user-created) `NDB` table must wait for the update to complete. This is true even when the transaction level of the read operation is `READ COMMITTED`.

One workaround which can be used to bypass potentially blocking reads is to force the SQL node to ignore the unique index when performing the read. This can be done by using the `IGNORE INDEX` index hint as part of the `SELECT` statement reading the table (see [Section 8.9.4, “Index Hints”](#)). Because the MySQL server creates a shadowing ordered index for every unique index created in `NDB`, this lets the ordered index be read instead, and avoids unique index access locking. The resulting read is as consistent as a committed read by primary key, returning the last committed value at the time the row is read.

Reading via an ordered index makes less efficient use of resources in the cluster, and may have higher latency.

It is also possible to avoid using the unique index for access by querying for ranges rather than for unique values.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

This behavior differs from that of other transactional storage engines such as `InnoDB` that may roll back individual statements.

- **Transactions and memory usage.**

As noted elsewhere in this chapter, NDB Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions

require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is affected as described in the following list:

- **TRUNCATE TABLE** is not transactional when used on **NDB** tables. If a **TRUNCATE TABLE** fails to empty the table, then it must be re-run until it is successful.
- **DELETE FROM** (even with no **WHERE** clause) *is* transactional. For tables containing a great many rows, you may find that performance is improved by using several **DELETE FROM ... LIMIT ...** statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use **TRUNCATE TABLE** instead.
- **LOAD DATA statements.** **LOAD DATA** is not transactional when used on **NDB** tables.

#### Important

When executing a **LOAD DATA** statement, the **NDB** engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

- **ALTER TABLE and transactions.** When copying an **NDB** table as part of an **ALTER TABLE**, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)
- **Transactions and the COUNT() function.** When using NDB Cluster Replication, it is not possible to guarantee the transactional consistency of the **COUNT()** function on the replica. In other words, when performing on the source a series of statements (**INSERT**, **DELETE**, or both) that changes the number of rows in a table within a single transaction, executing **SELECT COUNT(\*) FROM table** queries on the replica may yield intermediate results. This is due to the fact that **SELECT COUNT(...)** may perform dirty reads, and is not a bug in the **NDB** storage engine. (See Bug #31321 for more information.)

### 21.1.7.4 NDB Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 **Temporary failure, distribution changed** and similar temporary errors.
- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also [Section 21.1.7.2, “Limits and Differences of NDB Cluster from Standard MySQL Limits”](#).

### 21.1.7.5 Limits Associated with Database Objects in NDB Cluster

Some database objects such as tables and indexes have different limitations when using the **NDBCLUSTER** storage engine:

- **Database and table names.** When using the **NDB** storage engine, the maximum allowed length both for database names and for table names is 63 characters. A statement using a database name or table name longer than this limit fails with an appropriate error.
- **Number of database objects.** The maximum number of *all* **NDB** database objects in a single NDB Cluster—including databases, tables, and indexes—is limited to 20320.

- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) that can belong to a given table is 512.
- **Attributes per key.** The maximum number of attributes per key is 32.
- **Row size.** The maximum permitted size of any one row is 14000 bytes.

Each `BLOB` or `TEXT` column contributes  $256 + 8 = 264$  bytes to this total; this includes `JSON` columns. See [String Type Storage Requirements](#), as well as [JSON Storage Requirements](#), for more information relating to these types.

In addition, the maximum offset for a fixed-width column of an `NDB` table is 8188 bytes; attempting to create a table that violates this limitation fails with NDB error 851 `Maximum offset for fixed-size columns exceeded`. For memory-based columns, you can work around this limitation by using a variable-width column type such as `VARCHAR` or defining the column as `COLUMN_FORMAT=DYNAMIC`; this does not work with columns stored on disk. For disk-based columns, you may be able to do so by reordering one or more of the table's disk-based columns such that the combined width of all but the disk-based column defined last in the `CREATE TABLE` statement used to create the table does not exceed 8188 bytes, less any possible rounding performed for some data types such as `CHAR` or `VARCHAR`; otherwise it is necessary to use memory-based storage for one or more of the offending column or columns instead.

- **BIT column storage per table.** The maximum combined width for all `BIT` columns used in a given `NDB` table is 4096.
- **FIXED column storage.** NDB Cluster 7.5 and later supports a maximum of 128 TB per fragment of data in `FIXED` columns. (Previously, this was 16 GB.)

### 21.1.7.6 Unsupported or Missing Features in NDB Cluster

A number of features supported by other storage engines are not supported for `NDB` tables. Trying to use any of these features in NDB Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by `NDB`, must be syntactically and otherwise valid.

- **Index prefixes.** Prefixes on indexes are not supported for `NDB` tables. If a prefix is used as part of an index specification in a statement such as `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, the prefix is not created by `NDB`.

A statement containing an index prefix, and creating or modifying an `NDB` table, must still be syntactically valid. For example, the following statement always fails with Error 1089 `Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys`, regardless of storage engine:

```
CREATE TABLE t1 (
 c1 INT NOT NULL,
 c2 VARCHAR(100),
 INDEX i1 (c2(500))
);
```

This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.

- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in [MyISAM](#).
- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- **Replication.** Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See [Section 21.6, “NDB Cluster Replication”](#), for more information.

Replication using global transaction identifiers (GTIDs) is not compatible with NDB Cluster, and is not supported in NDB Cluster 7.5 or NDB CLuster 7.6. Do not enable GTIDs when using the [NDB](#) storage engine, as this is very likely to cause problems up to and including failure of NDB Cluster Replication.

Semisynchronous replication is not supported in NDB Cluster.

When replicating between clusters, it is possible to use IPv6 addresses between SQL nodes in different clusters, but all connections within a given cluster must use IPv4 addressing. For more information, see [NDB Cluster Replication and IPv6](#).

- **Generated columns.** The [NDB](#) storage engine does not support indexes on virtual generated columns.

As with other storage engines, you can create an index on a stored generated column, but you should bear in mind that [NDB](#) uses [DataMemory](#) for storage of the generated column as well as [IndexMemory](#) for the index. See [JSON columns and indirect indexing in NDB Cluster](#), for an example.

NDB Cluster writes changes in stored generated columns to the binary log, but does not log those made to virtual columns. This should not effect NDB Cluster Replication or replication between [NDB](#) and other MySQL storage engines.

#### Note

See [Section 21.1.7.3, “Limits Relating to Transaction Handling in NDB Cluster”](#), for more information relating to limitations on transaction handling in [NDB](#).

### 21.1.7.7 Limitations Relating to Performance in NDB Cluster

The following performance issues are specific to or especially pronounced in NDB Cluster:

- **Range scans.** There are query performance issues due to sequential access to the [NDB](#) storage engine; it is also relatively more expensive to do many range scans than it is with either [MyISAM](#) or [InnoDB](#).
- **Reliability of Records in range.** The [Records in range](#) statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ [USE INDEX](#) or [FORCE INDEX](#) to alter the execution plan. See [Section 8.9.4, “Index Hints”](#), for more information on how to do this.
- **Unique hash indexes.** Unique hash indexes created with [USING HASH](#) cannot be used for accessing a table if [NULL](#) is given as part of the key.

### 21.1.7.8 Issues Exclusive to NDB Cluster

The following are limitations specific to the [NDB](#) storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running [mysql](#) or other clients that may be accessing the cluster's SQL nodes.
- **Binary logging.**  
NDB Cluster has the following limitations or restrictions with regard to binary logging:
  - [sql\\_log\\_bin](#) has no effect on data operations; however, it is supported for schema operations.
  - NDB Cluster cannot produce a binary log for tables having [BLOB](#) columns but no primary key.

- Only the following schema operations are logged in a cluster binary log which is *not* on the `mysqld` executing the statement:
  - `CREATE TABLE`
  - `ALTER TABLE`
  - `DROP TABLE`
  - `CREATE DATABASE / CREATE SCHEMA`
  - `DROP DATABASE / DROP SCHEMA`
  - `CREATE TABLESPACE`
  - `ALTER TABLESPACE`
  - `DROP TABLESPACE`
  - `CREATE LOGFILE GROUP`
  - `ALTER LOGFILE GROUP`
  - `DROP LOGFILE GROUP`
- **Schema operations.** Schema operations (DDL statements) are rejected while any data node restarts. Schema operations are also not supported while performing an online upgrade or downgrade.
- **Number of fragment replicas.** The number of fragment replicas, as determined by the `NoOfReplicas` data node configuration parameter, is the number of copies of all data stored by NDB Cluster. Setting this parameter to 1 means there is only a single copy; in this case, no redundancy is provided, and the loss of a data node entails loss of data. To guarantee redundancy, and thus preservation of data even if a data node fails, set this parameter to 2, which is the default and recommended value in production.

Setting `NoOfReplicas` to a value greater than 2 is possible (to a maximum of 4) but unnecessary to guard against loss of data. In addition, *values greater than 2 for this parameter are not supported in production.*

See also [Section 21.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

### 21.1.7.9 Limitations Relating to NDB Cluster Disk Data Storage

**Disk Data object maximums and minimums.** Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces:  $2^{32}$  (4294967296)
- Maximum number of data files per tablespace:  $2^{16}$  (65536)
- The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See [Section 13.1.19, “CREATE TABLESPACE Statement”](#), for more information.

In addition, when working with NDB Disk Data tables, you should be aware of the following issues regarding data files and extents:

- Data files use `DataMemory`. Usage is the same as for in-memory data.
- Data files use file descriptors. It is important to keep in mind that data files are always open, which means the file descriptors are always in use and cannot be re-used for other system tasks.

- Extents require sufficient `DiskPageBufferMemory`; you must reserve enough for this parameter to account for all memory used by all extents (number of extents times size of extents).

**Disk Data tables and diskless mode.** Use of Disk Data tables is not supported when running the cluster in diskless mode.

### 21.1.7.10 Limitations Relating to Multiple NDB Cluster Nodes

#### Multiple SQL nodes.

The following are issues relating to the use of multiple MySQL servers as NDB Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **Stored programs not distributed.** Stored procedures, stored functions, triggers, and scheduled events are all supported by tables using the `NDB` storage engine, but these do *not* propagate automatically between MySQL Servers acting as Cluster SQL nodes, and must be re-created separately on each SQL node. See [Stored Programs in NDB Cluster](#).
- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)
- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, NDB Cluster does not support distributed table locks.)

#### Multiple management nodes.

When using multiple management servers:

- If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.
- When a management server starts, it first checks for any other management server in the same NDB Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server `--reload` and `--initial` startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of an NDB Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this NDB Cluster. See [Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”](#), for more information.

#### Multiple network addresses.

Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

#### Note

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it is not possible to use more than one `[tcp]` section per connection in the `config.ini` file. See [Section 21.3.3.10, “NDB Cluster TCP/IP Connections”](#), for more information.

## 21.2 NDB Cluster Installation

This section describes the basics for planning, installing, configuring, and running an NDB Cluster. Whereas the examples in [Section 21.3, “Configuration of NDB Cluster”](#) provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable NDB Cluster which meets the *minimum* requirements for availability and safeguarding of data.

For information about upgrading or downgrading an NDB Cluster between release versions, see [Section 21.2.7, “Upgrading and Downgrading NDB Cluster”](#).

This section covers hardware and software requirements; networking issues; installation of NDB Cluster; basic configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

**GUI installation.** NDB Cluster also provides the NDB Cluster Auto-Installer (now deprecated), a web-based graphical installer, as part of the NDB Cluster distribution. The Auto-Installer can be used to perform basic installation and setup of an NDB Cluster on one (for testing) or more host computers. The Auto-Installer was changed in NDB 7.6 and differs in many respects from the version found in NDB 7.5 and earlier. [Section 21.2.8, “The NDB Cluster Auto-Installer \(NDB 7.5\) \(No longer supported\)”](#), has information about the Auto-Installer for NDB 7.5; if you are using NDB 7.6, see [Section 21.2.9, “The NDB Cluster Auto-Installer \(NDB 7.6\) \(No longer supported\)”](#).

**Assumptions.** The following sections make a number of assumptions regarding the cluster's physical and network configuration. These assumptions are discussed in the next few paragraphs.

**Cluster nodes and host computers.** The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

**Table 21.4 Network addresses of nodes in example cluster**

| Node                                  | IP Address    |
|---------------------------------------|---------------|
| Management node ( <code>mgmd</code> ) | 198.51.100.10 |
| SQL node ( <code>mysqld</code> )      | 198.51.100.20 |
| Data node "A" ( <code>ndbd</code> )   | 198.51.100.30 |
| Data node "B" ( <code>ndbd</code> )   | 198.51.100.40 |

This setup is also shown in the following diagram:

**Figure 21.4 NDB Cluster Multi-Computer Setup**

**Network addressing.** In the interest of simplicity (and reliability), this *How-To* uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `hosts` file (typically `/etc/hosts` for Linux and other Unix-like operating systems, `C:\WINDOWS\system32\drivers\etc\hosts` on Windows, or your operating system's equivalent) for providing a means to do host lookup if such is available.

**Potential hosts file issues.** A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
ndb1 /etc/hosts:
127.0.0.1 ndb1.cluster ndb1 localhost.localdomain localhost
```

```
ndb2 /etc/hosts:
127.0.0.1 ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```
ndb1 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb1.cluster ndb1
```

```
ndb2 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

### Caution

You cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for all `config.ini HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

**Host computer type.** Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

**Network hardware.** Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards or all four machines should have 1 Gbps cards.) NDB Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

### Important

NDB Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run an NDB Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

**Sample data.** We use the `world` database which is available for download from the MySQL website (see <https://dev.mysql.com/doc/index-other.html>). We assume that each machine has sufficient memory for running the operating system, required NDB Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see [Chapter 2, \*Installing and Upgrading MySQL\*](#). For information about installation of NDB Cluster on Linux and other Unix-like operating systems, see [Section 21.2.1, “Installation of NDB Cluster on Linux”](#). For information about installation of NDB Cluster on Windows operating systems, see [Section 21.2.2, “Installing NDB Cluster on Windows”](#).

For general information about NDB Cluster hardware, software, and networking requirements, see [Section 21.1.3, “NDB Cluster Hardware, Software, and Networking Requirements”](#).

## 21.2.1 Installation of NDB Cluster on Linux

This section covers installation methods for NDB Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms. For manual installation and setup instructions specific to Windows systems, see [Section 21.2.2, “Installing NDB Cluster on Windows”](#).

Each NDB Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (`mysqld`). Management nodes require the management server daemon (`ndb_mgmd`); data nodes require the data node daemon (`ndbd` or `ndbmt`). It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (`ndb_mgm`) on the management server host.

Installation of NDB Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a .tar.gz archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the NDB Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See [Section 21.2.3, “Initial Configuration of NDB Cluster”](#).

### 21.2.1.1 Installing an NDB Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the binary archive from the [NDB Cluster downloads page](#). (For the most recent 64-bit NDB 7.5 release, this is `mysql-cluster-gpl-7.5.22-linux-glibc2.12-x86_64.tar.gz`.) We assume that you have placed this file in each machine's `/var/tmp` directory.

If you require a custom binary, see [Section 2.9.5, “Installing MySQL Using a Development Source Tree”](#).

#### Note

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see [Section 21.2.3, “Initial Configuration of NDB Cluster”](#)).

**SQL nodes.** On each of the machines designated to host SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

```
shell> groupadd mysql
shell> useradd -g mysql -s /bin/false mysql
```

The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named `mysql` to the `mysql` directory.

#### Note

The actual file and directory names vary according to the NDB Cluster version number.

```
shell> cd /var/tmp
shell> tar -C /usr/local -xzvf mysql-cluster-gpl-7.5.22-linux-glibc2.12-x86_64.tar.gz
shell> ln -s /usr/local/mysql-cluster-gpl-7.5.22-linux-glibc2.12-x86_64 /usr/local/mysql
```

3. Change location to the `mysql` directory and set up the system databases using `mysqld --initialize` as shown here:

```
shell> cd mysql
shell> mysqld --initialize
```

This generates a random password for the MySQL `root` account. If you do *not* want the random password to be generated, you can substitute the `--initialize-insecure` option for `--initialize`. In either case, you should review [Section 2.10.1, “Initializing the Data Directory”](#), for additional information before performing this step. See also [Section 4.4.4, “mysql\\_secure\\_installation — Improve MySQL Installation Security”](#).

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

**Data nodes.** Installation of the data nodes does not require the `mysqld` binary. Only the NDB Cluster data node executable `ndbd` (single-threaded) or `ndbmttd` (multithreaded) is required. These binaries can also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the `/var/tmp` directory, and extract the `ndbd` and `ndbmttd` binaries from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxf mysql-cluster-gpl-7.5.22-linux-glibc2.12-x86_64.tar.gz
shell> cd mysql-cluster-gpl-7.5.22-linux-glibc2.12-x86_64
```

```
shell> cp bin/ndbd /usr/local/bin/ndbd
shell> cp bin/ndbmtd /usr/local/bin/ndbmtd
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb*
```

The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run an NDB Cluster data node, we have shown you how to install both `ndbd` and `ndbmtd` in the preceding instructions. We recommend that you do this when installing or upgrading NDB Cluster, even if you plan to use only one of them, since this should save time and trouble in the event that you later decide to change from one to the other.

#### Note

The data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See [Section 21.2.3, “Initial Configuration of NDB Cluster”](#).)

**Management nodes.** Installation of the management node does not require the `mysqld` binary. Only the NDB Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root`, perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zvxf mysql-cluster-gpl-7.5.22-linux-glibc2.12-x86_64.tar.gz
shell> cd mysql-cluster-gpl-7.5.22-linux-glibc2.12-x86_64
shell> cp bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

In [Section 21.2.3, “Initial Configuration of NDB Cluster”](#), we create configuration files for all of the nodes in our example NDB Cluster.

### 21.2.1.2 Installing NDB Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of NDB Cluster node using RPM packages supplied by Oracle beginning with NDB 7.5.4. For information about RPMs for previous versions of NDB Cluster, see [Installation using old-style RPMs \(NDB 7.5.3 and earlier\)](#).

As an alternative to the method described in this section, Oracle provides MySQL Repositories for NDB Cluster 7.5.6 and later that are compatible with many common Linux distributions. Two repositories, listed here, are available for RPM-based distributions:

- For distributions using `yum` or `dnf`, you can use the MySQL Yum Repository for NDB Cluster. See [Installing MySQL NDB Cluster Using the Yum Repository](#), for instructions and additional information.
- For SLES, you can use the MySQL SLES Repository for NDB Cluster. See [Installing MySQL NDB Cluster Using the SLES Repository](#), for instructions and additional information.

RPMs are available for both 32-bit and 64-bit Linux platforms. The filenames for these RPMs use the following pattern:

```
mysql-cluster-community-data-node-7.5.8-1.el7.x86_64.rpm
mysql-cluster-license-component-ver-rev.distro.arch.rpm

license: {commercial | community}

component: {management-server | data-node | server | client | other-see text}

ver: major.minor.release

rev: major[.minor]

distro: {el6 | el7 | sles12}

arch: {i686 | x86_64}
```

`license` indicates whether the RPM is part of a Commercial or Community release of NDB Cluster. In the remainder of this section, we assume for the examples that you are installing a Community release.

Possible values for `component`, with descriptions, can be found in the following table:

**Table 21.5 Components of the NDB Cluster RPM distribution**

| Component                      | Description                                                                                                                                                      |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>auto-installer</code>    | NDB Cluster Auto Installer program (DEPRECATED); see <a href="#">Section 21.2.8, “The NDB Cluster Auto-Installer (NDB 7.5) (No longer supported)</a> , for usage |
| <code>client</code>            | MySQL and NDB client programs; includes <code>mysql</code> client, <code>ndb_mgm</code> client, and other client tools                                           |
| <code>common</code>            | Character set and error message information needed by the MySQL server                                                                                           |
| <code>data-node</code>         | <code>ndbd</code> and <code>ndbmttd</code> data node binaries                                                                                                    |
| <code>devel</code>             | Headers and library files needed for MySQL client development                                                                                                    |
| <code>embedded</code>          | Embedded MySQL server                                                                                                                                            |
| <code>embedded-compat</code>   | Backwards-compatible embedded MySQL server                                                                                                                       |
| <code>embedded-devel</code>    | Header and library files for developing applications for embedded MySQL                                                                                          |
| <code>java</code>              | JAR files needed for support of ClusterJ applications                                                                                                            |
| <code>libs</code>              | MySQL client libraries                                                                                                                                           |
| <code>libs-compat</code>       | Backwards-compatible MySQL client libraries                                                                                                                      |
| <code>management-server</code> | The NDB Cluster management server ( <code>ndb_mgmd</code> )                                                                                                      |
| <code>memcached</code>         | Files needed to support <code>ndbmemcache</code>                                                                                                                 |
| <code>minimal-debuginfo</code> | Debug information for package server-minimal; useful when developing applications that use this package or when debugging this package                           |

| Component                       | Description                                                                                                                |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ndbclient</a>       | NDB client library for running NDB API and MGM API applications ( <a href="#">libndbclient</a> )                           |
| <a href="#">ndbclient-devel</a> | Header and other files needed for developing NDB API and MGM API applications                                              |
| <a href="#">nodejs</a>          | Files needed to set up Node.JS support for NDB Cluster                                                                     |
| <a href="#">server</a>          | The MySQL server ( <a href="#">mysqld</a> ) with NDB storage engine support included, and associated MySQL server programs |
| <a href="#">server-minimal</a>  | Minimal installation of the MySQL server for NDB and related tools                                                         |
| <a href="#">test</a>            | <a href="#">mysqltest</a> , other MySQL test programs, and support files                                                   |

A single bundle (.tar file) of all NDB Cluster RPMs for a given platform and architecture is also available. The name of this file follows the pattern shown here:

```
mysql-cluster-license-ver-rev.distro.arch.rpm-bundle.tar
```

You can extract the individual RPM files from this file using [tar](#) or your preferred tool for extracting archives.

The components required to install the three major types of NDB Cluster nodes are given in the following list:

- *Management node*: [management-server](#)
- *Data node*: [data-node](#)
- *SQL node*: [server](#) and [common](#)

In addition, the [client](#) RPM should be installed to provide the [ndb\\_mgm](#) management client on at least one management node. You may also wish to install it on SQL nodes, to have [mysql](#) and other MySQL client programs available on these. We discuss installation of nodes by type later in this section.

[ver](#) represents the three-part NDB storage engine version number in 7.5.x format, shown as 7.5.22 in the examples. [rev](#) provides the RPM revision number in major.minor format. In the examples shown in this section, we use 1.1 for this value.

The [distro](#) (Linux distribution) is one of [rhel5](#) (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), [el6](#) (Oracle Linux 6, Red Hat Enterprise Linux 6), [el7](#) (Oracle Linux 7, Red Hat Enterprise Linux 7), or [sles12](#) (SUSE Enterprise Linux 12). For the examples in this section, we assume that the host runs Oracle Linux 7, Red Hat Enterprise Linux 7, or the equivalent ([el7](#)).

[arch](#) is [i686](#) for 32-bit RPMs and [x86\\_64](#) for 64-bit versions. In the examples shown here, we assume a 64-bit platform.

The NDB Cluster version number in the RPM file names (shown here as 7.5.22) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number.* The architecture should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs ([x86\\_64](#)) cannot be used with 32-bit operating systems (use [i686](#) for the latter).

**Data nodes.** On a computer that is to host an NDB Cluster data node it is necessary to install only the [data-node](#) RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv mysql-cluster-community-data-node-7.5.22-1.el7.x86_64.rpm
```

This installs the `ndbd` and `ndbmttd` data node binaries in `/usr/sbin`. Either of these can be used to run a data node process on this host.

**SQL nodes.** Copy the `server` and `common` RPMs to each machine to be used for hosting an NDB Cluster SQL node (`server` requires `common`). Install the `server` RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv mysql-cluster-community-server-7.5.22-1.el7.x86_64.rpm
```

This installs the MySQL server binary (`mysqld`), with `NDB` storage engine support, in the `/usr/sbin` directory. It also installs all needed MySQL Server support files and useful MySQL server programs, including the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

### Important

You must use the versions of these RPMs released for NDB Cluster ; those released for the standard MySQL server do not provide support for the `NDB` storage engine.

To administer the SQL node (MySQL server), you should also install the `client` RPM, as shown here:

```
shell> rpm -Uhv mysql-cluster-community-client-7.5.22-1.el7.x86_64.rpm
```

This installs the `mysql` client and other MySQL client programs, such as `mysqladmin` and `mysqldump`, to `/usr/bin`.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the `management-server` RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the `management-server` RPM downloaded from the MySQL website):

```
shell> rpm -Uhv mysql-cluster-community-management-server-7.5.22-1.el7.x86_64.rpm
```

This RPM installs the management server binary `ndb_mgmd` in the `/usr/sbin` directory. While this is the only program actually required for running a management node, it is also a good idea to have the `ndb_mgm` NDB Cluster management client available as well. You can obtain this program, as well as other `NDB` client programs such as `ndb_desc` and `ndb_config`, by installing the `client` RPM as described previously.

### Note

Previously, `ndb_mgm` was installed by the same RPM used to install the management server. In NDB 7.5.4 and later, all `NDB` client programs are obtained from the same `client` RPM that installs `mysql` and other MySQL clients.

See [Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle”](#), for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster; see [Section 21.2.3, “Initial Configuration of NDB Cluster”](#), for the relevant information.

**Installation using old-style RPMs (NDB 7.5.3 and earlier).** *The information in the remainder of this section applies only to NDB 7.5.3 and earlier*, and provides the steps necessary to install the correct executables for each type of NDB Cluster node using “old-style” RPM packages as supplied by Oracle prior to NDB 7.5.4. The filenames for these “old-style” RPMs use the following pattern:

```
MySQL-Cluster-component-producttype-ndbversion-revision.distribution.architecture.rpm
```

```

component:= {server | client [| other]}

producttype:= {gpl | advanced}

ndbversion:= major.minor.release

distribution:= {sles11 | rhel5 | el6}

architecture:= {i386 | x86_64}

```

The `component` can be `server` or `client`. (Other values are possible, but since only the `server` and `client` components are required for a working NDB Cluster installation, we do not discuss them here.) The `producttype` for Community RPMs downloaded from <https://dev.mysql.com/downloads/cluster/> is always `gpl`; `advanced` is used to indicate commercial releases. `ndbversion` represents the three-part NDB storage engine version number in `7.5.x` format; we use `7.5.3` throughout the rest of this section. The RPM `revision` is shown as `1` in the examples following. The `distribution` can be one of `sles12` (SUSE Enterprise Linux 12), `rhel6` (Oracle Linux 6, Red Hat Enterprise Linux 6), or `el7` (Oracle Linux 7, Red Hat Enterprise Linux 7). The `architecture` is `i386` for 32-bit RPMs and `x86_64` for 64-bit versions.

For an NDB Cluster, one and possibly two RPMs are required:

- The `server` RPM (for example, `MySQL-Cluster-server-gpl-7.5.3-1.sles11.i386.rpm`), which supplies the core files needed to run a MySQL Server with `NDBCLUSTER` storage engine support (that is, as an NDB Cluster SQL node) as well as all NDB Cluster executables, including the management node, data node, and `ndb_mgm` client binaries. This RPM is always required for installing NDB Cluster.
- If you do not have your own client application capable of administering a MySQL server, you should also obtain and install the `client` RPM (for example, `MySQL-Cluster-client-gpl-7.5.3-1.sles11.i386.rpm`), which supplies the `mysql` client

*It is very important that all of the Cluster RPMs to be installed have the same version number. The `architecture` designation should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs cannot be used with 32-bit operating systems.*

**Data nodes.** On a computer that is to host a cluster data node it is necessary to install only the `server` RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
shell> rpm -Uvh MySQL-Cluster-server-gpl-7.5.22-1.sles11.i386.rpm
```

Although this installs all NDB Cluster binaries, only the program `ndbd` or `ndbmttd` (both in `/usr/sbin`) is actually needed to run an NDB Cluster data node.

**SQL nodes.** On each machine to be used for hosting a cluster SQL node, install the `server` RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
shell> rpm -Uvh MySQL-Cluster-server-gpl-7.5.22-1.sles11.i386.rpm
```

This installs the MySQL server binary (`mysqld`) with NDB storage engine support in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

To administer the SQL node (MySQL server), you should also install the `client` RPM, as shown here:

```
shell> rpm -Uvh MySQL-Cluster-client-gpl-7.5.22-1.sles11.i386.rpm
```

This installs the `mysql` client program.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the `server` RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the `server` RPM downloaded from the MySQL website):

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.3.33-1.sles11.i386.rpm
```

Although this RPM installs many other files, only the management server binary `ndb_mgmd` (in the `/usr/sbin` directory) is actually required for running a management node. The `server` RPM also installs `ndb_mgm`, the NDB management client.

See [Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle”](#), for general information about installing MySQL using RPMs supplied by Oracle. See [Section 21.2.3, “Initial Configuration of NDB Cluster”](#), for information about required post-installation configuration.

### 21.2.1.3 Installing NDB Cluster Using .deb Files

The section provides information about installing NDB Cluster on Debian and related Linux distributions such Ubuntu using the `.deb` files supplied by Oracle for this purpose.

For NDB Cluster 7.5.6 and later, Oracle also provides an APT repository for Debian and other distributions. See [Installing MySQL NDB Cluster Using the APT Repository](#), for instructions and additional information.

Oracle provides `.deb` installer files for NDB Cluster 7.5 for 32-bit and 64-bit platforms. For a Debian-based system, only a single installer file is necessary. This file is named using the pattern shown here, according to the applicable NDB Cluster version, Debian version, and architecture:

```
mysql-cluster-gpl-ndbver-debiandebianver-arch.deb
```

Here, `ndbver` is the 3-part NDB engine version number, `debianver` is the major version of Debian (8 or 9), and `arch` is one of `i686` or `x86_64`. In the examples that follow, we assume you wish to install NDB 7.5.22 on a 64-bit Debian 9 system; in this case, the installer file is named `mysql-cluster-gpl-7.5.22-debian9-x86_64.deb-bundle.tar`.

Once you have downloaded the appropriate `.deb` file, you can untar it, and then install it from the command line using `dpkg`, like this:

```
shell> dpkg -i mysql-cluster-gpl-7.5.22-debian9-i686.deb
```

You can also remove it using `dpkg` as shown here:

```
shell> dpkg -r mysql
```

The installer file should also be compatible with most graphical package managers that work with `.deb` files, such as `GDebi` for the Gnome desktop.

The `.deb` file installs NDB Cluster under `/opt/mysql/server-version/`, where `version` is the 2-part release series version for the included MySQL server. For NDB 7.5, this is always 5.7. The directory layout is the same as that for the generic Linux binary distribution (see [Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”](#)), with the exception that startup scripts and configuration files are found in `support-files` instead of `share`. All NDB Cluster executables, such as `ndb_mgm`, `ndbd`, and `ndb_mgmd`, are placed in the `bin` directory.

### 21.2.1.4 Building NDB Cluster from Source on Linux

This section provides information about compiling NDB Cluster on Linux and other Unix-like platforms. Building NDB Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see [Section 2.9, “Installing MySQL from Source”](#). For information about compiling NDB Cluster on Windows platforms, see [Section 21.2.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).

Building NDB Cluster requires using the NDB Cluster sources. These are available from the NDB Cluster downloads page at <https://dev.mysql.com/downloads/cluster/>. The archived source file should

have a name similar to `mysql-cluster-gpl-7.5.22.tar.gz`. You can also obtain NDB Cluster sources from GitHub at <https://github.com/mysql/mysql-server/tree/cluster-7.5> (NDB 7.5) and <https://github.com/mysql/mysql-server/tree/cluster-7.6> (NDB 7.6). *Building NDB Cluster 7.5 or 7.6 from standard MySQL Server 5.7 sources is not supported.*

The `WITH_NDBCLOUD_STORAGE_ENGINE` option for `CMake` causes the binaries for the management nodes, data nodes, and other NDB Cluster programs to be built; it also causes `mysqld` to be compiled with `NDB` storage engine support. This option (or its alias `WITH_NDBCLOUD`) is required when building NDB Cluster.

#### Important

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if `CMake` cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about `CMake` options specific to building NDB Cluster, see [Options for Compiling NDB Cluster](#).

After you have run `make && make install` (or your system's equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location.

**Management nodes.** When building from source and running the default `make install`, the management server and management client binaries (`ndb_mgmd` and `ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

**Data nodes.** The only executable required on a data node host is the data node binary `ndbd` or `ndbmttd`. (`mysqld`, for example, does not have to be present on the host machine.) By default, when building from source, this file is placed in the directory `/usr/local/mysql/bin`. For installing on multiple data node hosts, only `ndbd` or `ndbmttd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) The data node binary need not be in any particular location on the host's file system, as long as the location is known.

When compiling NDB Cluster from source, no special options are required for building multithreaded data node binaries. Configuring the build with `NDB` storage engine support causes `ndbmttd` to be built automatically; `make install` places the `ndbmttd` binary in the installation `bin` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

**SQL nodes.** If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system `root` user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in [Section 2.9, “Installing MySQL from Source”](#) to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from [Section 2.9, “Installing MySQL from Source”](#) on each machine. If you configure the build with a nondefault `PREFIX` option, you must adjust the directory accordingly.

In [Section 21.2.3, “Initial Configuration of NDB Cluster”](#), we create configuration files for all of the nodes in our example NDB Cluster.

## 21.2.2 Installing NDB Cluster on Windows

This section describes installation procedures for NDB Cluster on Windows hosts. NDB Cluster 7.5 binaries for Windows can be obtained from <https://dev.mysql.com/downloads/cluster/>. For information about installing NDB Cluster on Windows from a binary release provided by Oracle, see [Section 21.2.2.1, “Installing NDB Cluster on Windows from a Binary Release”](#).

It is also possible to compile and install NDB Cluster from source on Windows using Microsoft Visual Studio. For more information, see [Section 21.2.2.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).

### 21.2.2.1 Installing NDB Cluster on Windows from a Binary Release

This section describes a basic installation of NDB Cluster on Windows using a binary “no-install” NDB Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see [Section 21.2, “NDB Cluster Installation”](#)), as shown in the following table:

**Table 21.6 Network addresses of nodes in example cluster**

| Node                                  | IP Address    |
|---------------------------------------|---------------|
| Management node ( <code>mgmd</code> ) | 198.51.100.10 |
| SQL node ( <code>mysqld</code> )      | 198.51.100.20 |
| Data node "A" ( <code>ndbd</code> )   | 198.51.100.30 |
| Data node "B" ( <code>ndbd</code> )   | 198.51.100.40 |

As on other platforms, the NDB Cluster host computer running an SQL node must have installed on it a MySQL Server binary (`mysqld.exe`). You should also have the MySQL client (`mysql.exe`) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (`ndb_mgmd.exe`); each data node requires the data node daemon (`ndbd.exe` or `ndbmtd.exe`). For this example, we refer to `ndbd.exe` as the data node executable, but you can install `ndbmtd.exe`, the multithreaded version of this program, instead, in exactly the same way. You should also install the management client (`ndb_mgm.exe`) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of NDB Cluster node.

#### Note

As with other Windows programs, NDB Cluster executables are named with the `.exe` file extension. However, it is not necessary to include the `.exe` extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as `mysqld`, `mysql`, `ndb_mgmd`, and so on. You should understand that, whether we refer (for example) to `mysqld` or `mysqld.exe`, either name means the same thing (the MySQL Server program).

For setting up an NDB Cluster using Oracle's `no-install` binaries, the first step in the installation process is to download the latest NDB Cluster Windows ZIP binary archive from <https://dev.mysql.com/downloads/cluster/>. This archive has a filename of the `mysql-cluster-gpl-ver-winarch.zip`, where `ver` is the NDB storage engine version (such as `7.5.22`), and `arch` is the architecture (`32` for 32-bit binaries, and `64` for 64-bit binaries). For example, the NDB Cluster 7.5.22 archive for 64-bit Windows systems is named `mysql-cluster-gpl-7.5.22-win64.zip`.

You can run 32-bit NDB Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit NDB Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit NDB Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

**SQL node.** We assume that you have placed a copy of the archive in the directory `C:\Documents and Settings\username\My Documents\Downloads` on the computer having the IP address `198.51.100.20`, where `username` is the name of the current user. (You can obtain this name using `ECHO %USERNAME%` on the command line.) To install and run NDB Cluster executables as Windows services, this user should be a member of the `Administrators` group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter `C:\`, which causes the Extraction Wizard to extract the archive to the directory `C:\mysql-cluster-gpl-ver-winarch`. Rename this directory to `C:\mysql`.

It is possible to install the NDB Cluster binaries to directories other than `C:\mysql\bin`; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than `C:\mysql` or `C:\Program Files\MySQL\MySQL Server 5.7`, or if the SQL node's data directory is in a location other than `C:\mysql\data` or `C:\Program Files\MySQL\MySQL Server 5.7\data`, extra configuration options must be used on the command line or added to the `my.ini` or `my.cnf` file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see [Section 2.3.4, “Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive”](#).

For a MySQL Server with NDB Cluster support to run as part of an NDB Cluster, it must be started with the options `--ndbcluster` and `--ndb-connectstring`. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
Options for mysqld process:
ndbcluster # run NDB storage engine
ndb-connectstring=198.51.100.10 # location of management server
```

You can add other options used by this MySQL Server if desired (see [Section 2.3.4.2, “Creating an Option File”](#)), but the file must contain the options shown, at a minimum. Save this file as `C:\mysql\my.ini`. This completes the installation and setup for the SQL node.

**Data nodes.** An NDB Cluster data node on a Windows host requires only a single executable, one of either `ndbd.exe` or `ndbmttd.exe`. For this example, we assume that you are using `ndbd.exe`, but the same instructions apply when using `ndbmttd.exe`. On each computer where you wish to run a data node (the computers having the IP addresses 198.51.100.30 and 198.51.100.40), create the directories `C:\mysql`, `C:\mysql\bin`, and `C:\mysql\cluster-data`; then, on the computer where you downloaded and extracted the `noinstall` archive, locate `ndbd.exe` in the `C:\mysql\bin` directory. Copy this file to the `C:\mysql\bin` directory on each of the two data node hosts.

To function as part of an NDB Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the `--ndb-connectstring` or `-c` option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
Options for data node process:
ndb-connectstring=198.51.100.10 # location of management server
```

Save this file as `C:\mysql\my.ini` on the data node host. Create another text file containing the same information and save it on as `C:\mysql\my.ini` on the other data node host, or copy the `my.ini` file from the first data node host to the second one, making sure to place the copy in the second data node's `C:\mysql` directory. Both data node hosts are now ready to be used in the NDB Cluster, which leaves only the management node to be installed and configured.

**Management node.** The only executable program required on a computer used for hosting an NDB Cluster management node is the management server program `ndb_mgmd.exe`. However, in order to administer the NDB Cluster once it has been started, you should also install the NDB Cluster management client program `ndb_mgm.exe` on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the `noinstall` archive; this should be the directory `C:\mysql\bin` on the SQL node host. Create the directory `C:\mysql\bin` on the computer having the IP address 198.51.100.10, then copy both programs to this directory.

You should now create two configuration files for use by `ndb_mgmd.exe`:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the NDB Cluster global configuration file (see item 2).

To create this file, start a new text file in Notepad or another text editor, and enter the following information:

```
[mysql_cluster]
Options for management node process
config-file=C:/mysql/bin/config.ini
```

Save this file as the text file `C:\mysql\bin\my.ini`.

2. A global configuration file from which the management node can obtain configuration information governing the NDB Cluster as a whole. At a minimum, this file must contain a section for each node in the NDB Cluster, and the IP addresses or hostnames for the management node and all data nodes (`HostName` configuration parameter). It is also advisable to include the following additional information:

- The IP address or hostname of any SQL nodes
- The data memory and index memory allocated to each data node (`DataMemory` and `IndexMemory` configuration parameters)
- The number of fragment replicas, using the `NoOfReplicas` configuration parameter (see [Section 21.1.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#))
- The directory where each data node stores its data and log file, and the directory where the management node keeps its log files (in both cases, the `DataDir` configuration parameter)

Create a new text file using a text editor such as Notepad, and input the following information:

```
[ndbd default]
Options affecting ndbd processes on all data nodes:
NoOfReplicas=2 # Number of fragment replicas
DataDir=C:/mysql/cluster-data # Directory for each data node's data files
 # Forward slashes used in directory path,
 # rather than backslashes. This is correct;
 # see Important note in text
DataMemory=80M # Memory allocated to data storage
IndexMemory=18M # Memory allocated to index storage
 # For DataMemory and IndexMemory, we have used the
 # default values. Since the "world" database takes up
 # only about 500KB, this should be more than enough for
 # this example Cluster setup.

[ndb_mgmd]
Management process options:
HostName=198.51.100.10 # Hostname or IP address of management node
DataDir=C:/mysql/bin/cluster-logs # Directory for management node log files

[ndbd]
Options for data node "A":
HostName=198.51.100.30 # (one [ndbd] section per data node)
 # Hostname or IP address

[ndbd]
Options for data node "B":
HostName=198.51.100.40 # Hostname or IP address

[mysqld]
SQL node options:
HostName=198.51.100.20 # Hostname or IP address
```

Save this file as the text file `C:\mysql\bin\config.ini`.

**Important**

A single backslash character (\) cannot be used when specifying directory paths in program options or configuration files used by NDB Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (\\), or replace the backslash with a forward slash character (/). For example, the following line from the [ndb\_mgmd] section of an NDB Cluster config.ini file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\\\\bin\\\\cluster-logs # Escaped backslashes
```

```
DataDir=C:/mysql/bin/cluster-logs # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in NDB Cluster program options and configuration files on Windows.

### 21.2.2.2 Compiling and Installing NDB Cluster from Source on Windows

Oracle provides precompiled NDB Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile NDB Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- Building NDB Cluster requires using the NDB Cluster sources. These are available from the NDB Cluster downloads page at <https://dev.mysql.com/downloads/cluster/>. The archived source file should have a name similar to mysql-cluster-gpl-7.5.22.tar.gz. You can also obtain NDB Cluster sources from GitHub at <https://github.com/mysql/mysql-server/tree/cluster-7.5> (NDB 7.5) and <https://github.com/mysql/mysql-server/tree/cluster-7.6> (NDB 7.6). *Building NDB Cluster 7.5 or 7.6 from standard MySQL Server 5.7 sources is not supported.*
- You must configure the build using the WITH\_NDBCLUSTER\_STORAGE\_ENGINE or WITH\_NDBCLUSTER option in addition to any other build options you wish to use with CMake. (WITH\_NDBCLUSTER is supported as an alias for WITH\_NDBCLUSTER\_STORAGE\_ENGINE, and works in exactly the same way.)

**Important**

The WITH\_NDB\_JAVA option is enabled by default. This means that, by default, if CMake cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using -DWITH\_NDB\_JAVA=OFF. (Bug #12379735) Use WITH\_CLASSPATH to provide the Java classpath if needed.

For more information about CMake options specific to building NDB Cluster, see [Options for Compiling NDB Cluster](#).

Once the build process is complete, you can create a Zip archive containing the compiled binaries; [Section 2.9.4, “Installing MySQL Using a Standard Source Distribution”](#) provides the commands needed to perform this task on Windows systems. The NDB Cluster binaries can be found in the bin directory of the resulting archive, which is equivalent to the no-install archive, and which can be installed and configured in the same manner. For more information, see [Section 21.2.2.1, “Installing NDB Cluster on Windows from a Binary Release”](#).

### 21.2.2.3 Initial Startup of NDB Cluster on Windows

Once the NDB Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the NDB Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process. The output should appear similar to what is shown here:

```
C:\mysql\bin> ndb_mgmd
2010-06-23 07:53:34 [MgmtSrvr] INFO -- NDB Cluster Management Server. mysql-5.7.33-ndb-7.5.23
2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used NDB Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of NDB Cluster data node processes running on Windows.) For this reason, do not close the window in which `ndb_mgmd.exe` is running; doing so kills the management node process. (See [Section 21.2.2.4, “Installing NDB Cluster Processes as Windows Services”](#), where we show how to install and run NDB Cluster processes as Windows services.)

The required `-f` option tells the management node where to find the global configuration file (`config.ini`). The long form of this option is `--config-file`.

#### Important

An NDB Cluster management node caches the configuration data that it reads from `config.ini`; once it has created a configuration cache, it ignores the `config.ini` file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read `config.ini` after you have corrected any errors in it. You can do this by starting `ndb_mgmd.exe` with the `--reload` or `--initial` option on the command line. Either of these options works to refresh the configuration cache.

It is not necessary or advisable to use either of these options in the management node's `my.ini` file.

2. On each of the data node hosts, run the command shown here to start the data node processes:

```
C:\mysql\bin> ndbd
2010-06-23 07:53:46 [ndbd] INFO -- Configuration fetched from 'localhost:1186', generation: 1
```

In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills `ndbd.exe`. (For more information, see [Section 21.2.2.4, “Installing NDB Cluster Processes as Windows Services”](#).)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the NDB Cluster management client `ndb_mgm.exe`, which should be in `C:\mysql\bin` on the management node host. (Do not try to re-use the console window where `ndb_mgmd.exe` is running by typing **CTRL+C**, as this kills the management node.) The resulting output should look like this:

```
C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
```

```
ndb_mgm>
```

When the prompt `ndb_mgm>` appears, this indicates that the management client is ready to receive NDB Cluster management commands. You can observe the status of the data nodes as they start by entering `ALL STATUS` at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

```
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-5.7.33-ndb-7.5.23)
Node 3: starting (Last completed phase 3) (mysql-5.7.33-ndb-7.5.23)

Node 2: starting (Last completed phase 4) (mysql-5.7.33-ndb-7.5.23)
Node 3: starting (Last completed phase 4) (mysql-5.7.33-ndb-7.5.23)

Node 2: Started (version 7.5.23)
Node 3: Started (version 7.5.23)

ndb_mgm>
```

### Note

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the `ndb_mgm` client. For more information, see [Section 21.5.1, “Commands in the NDB Cluster Management Client”](#).

The output produced by `ALL STATUS` is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the NDB Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave `ndb_mgm.exe` running; it has no negative impact on the performance of the NDB Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the NDB Cluster binaries (if you are following our example, this is `C:\mysql\bin`).

Start the SQL node by invoking `mysqld.exe` from the command line, as shown here:

```
C:\mysql\bin> mysqld --console
```

The `--console` option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it out without the `--console` option, so that logging is performed normally.)

In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the `SHOW` command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=2 @198.51.100.30 (Version: 5.7.33-ndb-7.5.23, Nodegroup: 0, *)
id=3 @198.51.100.40 (Version: 5.7.33-ndb-7.5.23, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @198.51.100.10 (Version: 5.7.33-ndb-7.5.23)
```

```
[mysqld(API)] 1 node(s)
id=4 @198.51.100.20 (Version: 5.7.33-ndb-7.5.23)
```

You can also verify that the SQL node is connected to the NDB Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` statement.

You should now be ready to work with database objects and data using NDB Cluster's `NDBCLUSTER` storage engine. See [Section 21.2.5, “NDB Cluster Example with Tables and Data”](#), for more information and examples.

You can also install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmttd.exe` as Windows services. For information on how to do this, see [Section 21.2.4.4, “Installing NDB Cluster Processes as Windows Services”](#).

#### 21.2.2.4 Installing NDB Cluster Processes as Windows Services

Once you are satisfied that NDB Cluster is running as desired, you can install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `SC START` and `SC STOP` commands, or using the Windows graphical `Services` utility. `NET START` and `NET STOP` commands can also be used.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'NDB Cluster Management Server'
as '"C:\mysql\bin\ndbd.exe" "--service=ndb_mgmd"'
Service successfully installed.
```

#### Important

When installing an NDB Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error `The system cannot find the file specified`.

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```
C:\> SC START ndb_mgmd
C:\> SC STOP ndb_mgmd
```

#### Note

If using `NET` commands, you can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```
C:\> NET START 'NDB Cluster Management Server'
The NDB Cluster Management Server service is starting.
The NDB Cluster Management Server service was started successfully.

C:\> NET STOP 'NDB Cluster Management Server'
The NDB Cluster Management Server service is stopping..
The NDB Cluster Management Server service was stopped successfully.
```

It is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` option, as shown in this example:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmld1
Installing service 'NDB Cluster Management Server'
 as '"C:\mysql\bin\ndb_mgmd.exe" "--service=mgmld1"'
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```
C:\> SC START mgmld1
C:\> SC STOP mgmld1
```

To remove the management node service, use `SC DELETE service_name`:

```
C:\> SC DELETE mgmld1
```

Alternatively, invoke `ndb_mgmd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'NDB Cluster Management Server'
Service successfully removed.
```

If you installed the service using a service name other than the default, pass the service name as the value of the `ndb_mgmd.exe --remove` option, like this:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmld1
Removing service 'mgmld1'
Service successfully removed.
```

Installation of an NDB Cluster data node process as a Windows service can be done in a similar fashion, using the `--install` option for `ndbd.exe` (or `ndbmttd.exe`), as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'NDB Cluster Data Node Daemon' as '"C:\mysql\bin\ndbd.exe" "--service=ndbd"'
Service successfully installed.
```

Now you can start or stop the data node as shown in the following example:

```
C:\> SC START ndbd
C:\> SC STOP ndbd
```

To remove the data node service, use `SC DELETE service_name`:

```
C:\> SC DELETE ndbd
```

Alternatively, invoke `ndbd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'NDB Cluster Data Node Daemon'
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install`, and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd.exe --install=dnode1
Installing service 'dnode1' as '"C:\mysql\bin\ndbd.exe" "--service=dnode1"'
Service successfully installed.

C:\> SC START dnode1
```

```
C:\> SC STOP dnodel
```

If you specified a service name when installing the data node service, you can use this name when removing it as well, as shown here:

```
C:\> SC DELETE dnodel
```

Alternatively, you can pass the service name as the value of the `ndbd.exe --remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove=dnodel
Removing service 'dnodel'
Service successfully removed.
```

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using `mysqld --install`, `SC START`, `SC STOP`, and `SC DELETE` (or `mysqld --remove`). .NET commands can also be used to start or stop a service. For additional information, see [Section 2.3.4.8, “Starting MySQL as a Windows Service”](#).

### 21.2.3 Initial Configuration of NDB Cluster

In this section, we discuss manual configuration of an installed NDB Cluster by creating and editing configuration files.

NDB Cluster also provides a GUI installer which can be used to perform the configuration without the need to edit text files in a separate application. For more information, see [Section 21.2.8, “The NDB Cluster Auto-Installer \(NDB 7.5\) \(No longer supported\)”](#).

For our four-node, four-host NDB Cluster (see [Cluster nodes and host computers](#)), it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connection string* that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

For more information on connection strings, see [Section 21.3.3.3, “NDB Cluster Connection Strings”](#).

- The management node needs a `config.ini` file telling it how many fragment replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

**Configuring the data nodes and SQL nodes.** The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

#### Note

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
[mysqld]
Options for mysqld process:
ndbcluster # run NDB storage engine

[mysql_cluster]
```

```
Options for NDB Cluster processes:
ndb-connectstring=198.51.100.10 # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

### Important

Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[mysqld]` and `[mysql_cluster]` sections of the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements fail with an error. This is by design.

**Configuring the management node.** The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
[ndbd default]
Options affecting ndbd processes on all data nodes:
NoOfReplicas=2 # Number of fragment replicas
DataMemory=80M # How much memory to allocate for data storage
IndexMemory=18M # How much memory to allocate for index storage
For DataMemory and IndexMemory, we have used the
default values. Since the "world" database takes up
only about 500KB, this should be more than enough for
this example NDB Cluster setup.
NOTE: IndexMemory is deprecated in NDB 7.6 and later; in
these versions, resources for all data and indexes are
allocated by DataMemory and any that are set for IndexMemory
are added to the DataMemory resource pool
ServerPort=2202 # This the default value; however, you can use any
port that is free for all the hosts in the cluster
Note1: It is recommended that you do not specify the port
number at all and simply allow the default value to be used
instead
Note2: The port was formerly specified using the PortNumber
TCP parameter; this parameter is no longer available in NDB
Cluster 7.5.

[ndb_mgmd]
Management process options:
HostName=198.51.100.10 # Hostname or IP address of management node
DataDir=/var/lib/mysql-cluster # Directory for management node log files

[ndbd]
Options for data node "A":
HostName=198.51.100.30 # (one [ndbd] section per data node)
NodeId=2 # Hostname or IP address
DataDir=/usr/local/mysql/data # Node ID for this data node
Directory for this data node's data files

[ndbd]
Options for data node "B":
HostName=198.51.100.40 # Hostname or IP address
NodeId=3 # Node ID for this data node
DataDir=/usr/local/mysql/data # Directory for this data node's data files

[mysqld]
SQL node options:
HostName=198.51.100.20 # Hostname or IP address
(additional mysqld connections can be
specified for this node for various
```

```
purposes such as running ndb_restore)
```

#### Note

The `world` database can be downloaded from <https://dev.mysql.com/doc/index-other.html>.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in [Section 21.2.4, “Initial Startup of NDB Cluster”](#).

For more detailed information about the available NDB Cluster configuration parameters and their uses, see [Section 21.3.3, “NDB Cluster Configuration Files”](#), and [Section 21.3, “Configuration of NDB Cluster”](#). For configuration of NDB Cluster as relates to making backups, see [Section 21.5.8.3, “Configuration for NDB Cluster Backups”](#).

#### Note

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

## 21.2.4 Initial Startup of NDB Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
shell> ndb_mgmd --initial -f /var/lib/mysql-cluster/config.ini
```

The first time that it is started, `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. This option requires that `--initial` or `--reload` also be specified; see [Section 21.4.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#), for details.

2. On each of the data node hosts, run this command to start the `ndbd` process:

```
shell> ndbd
```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=2 @198.51.100.30 (Version: 5.7.33-ndb-7.5.23, Nodegroup: 0, *)
id=3 @198.51.100.40 (Version: 5.7.33-ndb-7.5.23, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
```

```
id=1 @198.51.100.10 (Version: 5.7.33-ndb-7.5.23)
[mysqld(API)] 1 node(s)
id=4 @198.51.100.20 (Version: 5.7.33-ndb-7.5.23)
```

The SQL node is referenced here as [mysqld(API)], which reflects the fact that the mysqld process is acting as an NDB Cluster API node.

#### Note

The IP address shown for a given NDB Cluster SQL or other API node in the output of SHOW is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in NDB Cluster. See [Section 21.2.5, “NDB Cluster Example with Tables and Data”](#), for a brief discussion.

## 21.2.5 NDB Cluster Example with Tables and Data

#### Note

The information in this section applies to NDB Cluster running on both Unix and Windows platforms.

Working with database tables and data in NDB Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the NDBCLUSTER storage engine. To specify this, use the ENGINE=NDBCLUSTER or ENGINE=NDB option when creating the table:

```
CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
```

Alternatively, for an existing table that uses a different storage engine, use ALTER TABLE to change the table to use NDBCLUSTER:

```
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

- Every NDBCLUSTER table has a primary key. If no primary key is defined by the user when a table is created, the NDBCLUSTER storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of mysqldump, you can open the SQL script in a text editor and add the ENGINE option to any table creation statements, or replace any existing ENGINE options. Suppose that you have the world sample database on another MySQL server that does not support NDB Cluster, and you want to export the city table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting city\_table.sql file contains this table creation statement (and the INSERT statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
 `ID` int(11) NOT NULL auto_increment,
 `Name` char(35) NOT NULL default '',
 `CountryCode` char(3) NOT NULL default '',
 `District` char(20) NOT NULL default '',
 `Population` int(11) NOT NULL default '0',
 PRIMARY KEY (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
```

```
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
 `ID` int(11) NOT NULL auto_increment,
 `Name` char(35) NOT NULL default '',
 `CountryCode` char(3) NOT NULL default '',
 `District` char(20) NOT NULL default '',
 `Population` int(11) NOT NULL default '0',
 PRIMARY KEY (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabul',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `198.51.100.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql` (for example, in the `/tmp` directory). Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.7.33-ndb-7.5.23

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see [Section 2.10.4, “Securing the Initial MySQL Account”](#).

It is worth taking into account that Cluster nodes do *not* make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes. See [Section 21.5.17.2, “NDB Cluster and MySQL Privileges”](#), for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----+-----+
| Name | Population |
+-----+-----+
| Bombay | 10500000 |
| Seoul | 9981619 |
| São Paulo | 9968485 |
| Shanghai | 9696300 |
| Jakarta | 9604900 |
+-----+-----+
5 rows in set (0.34 sec)

mysql> \q
Bye

shell>
```

Applications that use MySQL can employ standard APIs to access NDB tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the `SELECT` statement just shown by using the PHP 5.X `mysqli` extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
 "http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
<meta http-equiv="Content-Type"
 content="text/html; charset=iso-8859-1">
<title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
 # connect to SQL node:
 $link = new mysqli('198.51.100.20', 'root', 'root_password', 'world');
 # parameters for mysqli constructor are:
 # host, user, password, database

 if(mysqli_connect_errno())
 die("Connect failed: " . mysqli_connect_error());

 $query = "SELECT Name, Population
 FROM City
 ORDER BY Population DESC
 LIMIT 5";

 # if no errors...
 if($result = $link->query($query))
 {
?>
<table border="1" width="40%" cellpadding="4" cellspacing ="1">
 <tbody>
 <tr>
```

```

<th width="10%>City</th>
<th>Population</th>
</tr>
<?
then display the results...
while($row = $result->fetch_object())
 printf("<tr>\n <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
 $row->Name, $row->Population);
?>
</tbody>
</table>
<?
...and verify the number of rows that were retrieved
printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
}
else
 # otherwise, tell us what went wrong
 echo mysqli_error();

free the result set and the mysqli connection object
$result->close();
$link->close();
?>
</body>
</html>

```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

## 21.2.6 Safe Shutdown and Restart of NDB Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmttd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `SC STOP service_name` or `NET STOP service_name`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (`198.51.100.10` in our example setup):

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

- On each of the data node hosts (`198.51.100.30` and `198.51.100.40`):

```
shell> ndbd
```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.
- On the SQL host (`198.51.100.20`):

```
shell> mysqld_safe &
```

On Windows platforms, assuming that you have installed all NDB Cluster processes as Windows services using the default service names (see [Section 21.2.2.4, “Installing NDB Cluster Processes as Windows Services”](#)), you can restart the cluster as follows:

- On the management host (`198.51.100.10` in our example setup), execute the following command:

```
C:\> SC START ndb_mgmd
```

- On each of the data node hosts ([198.51.100.30](#) and [198.51.100.40](#)), execute the following command:

```
C:\> SC START ndbd
```

- On the management node host, use the `ndb_mgm` client to verify that the management node and both data nodes have started successfully (see [Section 21.2.2.3, “Initial Startup of NDB Cluster on Windows”](#)).
- On the SQL node host ([198.51.100.20](#)), execute the following command:

```
C:\> SC START mysql
```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a *rolling restart* of the cluster. For more information about doing this, see [Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”](#).

## 21.2.7 Upgrading and Downgrading NDB Cluster

The following sections provide information about upgrading and downgrading NDB Cluster 7.5 and 7.6.

### 21.2.7.1 Upgrading and Downgrading NDB 7.5

This section provides information about compatibility between different NDB Cluster 7.5 releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. Additional information can also be found here regarding downgrades from NDB 7.5 to previous NDB release series. You should already be familiar with installing and configuring NDB Cluster prior to attempting an upgrade or downgrade. See [Section 21.3, “Configuration of NDB Cluster”](#).

Schema operations, including SQL DDL statements, cannot be performed while any data nodes are restarting, and thus during an online upgrade or downgrade of the cluster. For other information regarding the rolling restart procedure used to perform an online upgrade, see [Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”](#).

#### Important

Only compatibility between MySQL versions with regard to `NDBCLUSTER` is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the NDB Cluster software.* See [Section 2.11, “Upgrading MySQL”](#). For information about upgrades to NDB 7.6, see [Section 21.2.7.2, “Upgrading and Downgrading NDB 7.6”](#).

The table shown here provides information on NDB Cluster upgrade and downgrade compatibility among different releases of NDB 7.5. Additional notes about upgrades and downgrades to, from, or within the NDB Cluster 7.5 release series can be found following the table.

**Figure 21.5 NDB Cluster Upgrade and Downgrade Compatibility, MySQL NDB Cluster 7.5**

**Version support.** The following versions of NDB Cluster are supported for upgrades to GA releases of NDB Cluster 7.5 (7.5.4 and later):

- NDB Cluster 7.4 GA releases (7.4.4 and later)
- NDB Cluster 7.3 GA releases (7.3.2 and later)

**Known Issues.** The following issues are known to occur when upgrading to or between NDB 7.5 releases:

- When upgrading from NDB 7.5.2 or 7.5.3 to a later version, the use of `mysqld` with the `--initialize` and `--ndbcluster` options together caused problems later running `mysql_upgrade`.

When run with `--initialize`, the server does not require NDB support; having NDB enabled at this time can cause problems with `ndbinfo` tables. To keep this from happening, the `--initialize` option now causes `mysqld` to ignore the `--ndbcluster` option if the latter is also specified.

A workaround for an upgrade that has failed for these reasons can be accomplished as follows:

1. Perform a rolling restart of the entire cluster
2. Delete all `.frm` files in the `data/ndbinfo` directory
3. Run `mysql_upgrade`.

(Bug #81689, Bug #82724, Bug #24521927, Bug #23518923)

- During an online upgrade from an NDB Cluster 7.3 release to an NDB 7.4 (or later) release, the failures of several data nodes running the lower version during local checkpoints (LCPs), and just prior to upgrading these nodes, led to additional node failures following the upgrade. This was due to lingering elements of the `EMPTY_LCP` protocol initiated by the older nodes as part of an LCP-plus-restart sequence, and which is no longer used in NDB 7.4 and later due to LCP optimizations implemented in those versions. This issue was fixed in NDB 7.5.4. (Bug #23129433)
- Beginning with NDB 7.5.2, the `ndb_binlog_index` table uses the `InnoDB` storage engine. (Use of the `MyISAM` storage engine for this table continues to be supported for backward compatibility.)

When upgrading a previous release to NDB 7.5.2 or later, you can use the `--force --upgrade-system-tables` options with `mysql_upgrade` so that it performs `ALTER TABLE ... ENGINE=INNODB` on the `ndb_binlog_index` table.

For more information, see [Section 21.6.4, “NDB Cluster Replication Schema and Tables”](#).

- Online upgrades from previous versions of NDB Cluster to NDB 7.5.1 were not possible due to missing entries in the matrix used to test upgrade compatibility between versions. (Bug #22024947)

Also in NDB 7.5.1, `mysql_upgrade` failed to upgrade the `sys` schema if a `sys` database directory existed but was empty. (Bug #81352, Bug #23249846, Bug #22875519)

### 21.2.7.2 Upgrading and Downgrading NDB 7.6

This section provides information about compatibility between different NDB Cluster 7.6 releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. Additional information can also be found here regarding downgrades from NDB 7.6 to previous NDB release series. You should already be familiar with installation and configuration of NDB Cluster prior to attempting an upgrade or downgrade. See [Section 21.3, “Configuration of NDB Cluster”](#).

The table shown here provides information on NDB Cluster upgrade and downgrade compatibility among different releases of NDB 7.6. Additional notes about upgrades and downgrades to, from, or within the NDB Cluster 7.6 release series can be found following the table.

**Figure 21.6 NDB Cluster Upgrade and Downgrade Compatibility, MySQL NDB Cluster 7.6**

**Version support.** The following versions of NDB Cluster are supported for upgrades to GA releases of NDB Cluster 7.6 (7.6.6 and later):

- NDB Cluster 7.5 GA releases (7.5.4 and later)
- NDB Cluster 7.4 GA releases (7.4.4 and later)
- NDB Cluster 7.3 GA releases (7.3.2 and later)

**Known issues.** The following issues are known to occur when upgrading to, downgrading from, or between NDB 7.6 releases:

**Changes in Disk Data file format.** Due to changes in disk format, upgrading to or downgrading from either of the versions listed here requires an initial node restart of each data node:

- NDB 7.6.2
- NDB 7.6.4

To avoid problems relating to the old format, you should re-create any existing tablespaces and undo log file groups when upgrading. You can do this by performing an initial restart of each data node (that is, using the `--initial` option) as part of the upgrade process.

If you are using Disk Data tables, a downgrade from *any* NDB 7.6 release to any NDB 7.5 or earlier release requires that you restart all data nodes with `--initial` as part of the downgrade process. This is because NDB 7.5 and earlier release series are not able to read the new Disk Data file format.

**IndexMemory changes.** If you are downgrading from NDB 7.6 to NDB 7.5 (or earlier), you must set an explicit value for [IndexMemory](#) in the cluster configuration file if none is already present. This is because NDB 7.6.2 (and later) does not use this parameter and sets it to 0 by default, whereas it is required in NDB 7.5 and earlier releases, in which the cluster refuses to start with [Invalid configuration received from Management Server...](#) if [IndexMemory](#) is not set to a nonzero value.

#### Important

Upgrading to NDB 7.6.4 or later from an earlier release, or downgrading from NDB 7.6.4 or later to an earlier release, requires purging then re-creating the [NDB](#) data node file system, which means that each data node must be restarted using the [--initial](#) option as part of the rolling restart or system restart normally required. (Starting a data node with no file system is already equivalent to an initial restart; in such cases, [--initial](#) is implied and not required. This is unchanged from previous releases of NDB Cluster.)

When such a restart is performed as part of an upgrade to NDB 7.6.4 or later, any existing LCP files are checked for the presence of the LCP [Sysfile](#), indicating that the existing data node file system was written using NDB 7.6.4 or later. If such a node file system exists, but does not contain the [Sysfile](#), and if any data nodes are restarted without the [--initial](#) option, [NDB](#) causes the restart to fail with an appropriate error message.

You should also be aware that no such protection is possible when downgrading from NDB 7.6.4 or later to a release previous to NDB 7.6.4.

### 21.2.8 The NDB Cluster Auto-Installer (NDB 7.5) (No longer supported)

#### Note

This feature is deprecated and should be avoided. It is subject to removal in a future version of NDB Cluster.

This section describes the web-based graphical configuration installer included as part of the NDB Cluster 7.5 distribution. If you are using NDB 7.6, see [Section 21.2.9, “The NDB Cluster Auto-Installer \(NDB 7.6\) \(No longer supported\)”,](#) for information about the updated installer that is supplied with NDB 7.6 releases.

Topics discussed in the following sections include an overview of the installer and its parts, software and other requirements for running the installer, navigating the GUI, and using the installer to set up, start, or stop an NDB Cluster on one or more host computers.

The NDB Cluster Auto-Installer is made up of two components. The front end is a GUI client implemented as a Web page that loads and runs in a standard Web browser such as Firefox or Microsoft Internet Explorer. The back end is a server process ([ndb\\_setup.py](#)) that runs on the local machine or on another host to which you have access.

These two components (client and server) communicate with each other using standard HTTP requests and responses. The back end can manage NDB Cluster software programs on any host where the back end user has granted access. If the NDB Cluster software is on a different host, the back end relies on SSH for access.

#### 21.2.8.1 NDB Cluster Auto-Installer Requirements

This section provides information on supported operating platforms and software, required software, and other prerequisites for running the NDB Cluster Auto-Installer.

**Supported platforms.** The NDB Cluster Auto-Installer is available with most NDB 7.5.2 and later NDB Cluster distributions for recent versions of Linux, Windows, Solaris, and macOS. For more

detailed information about platform support for NDB Cluster and the NDB Cluster Auto-Installer, see <https://www.mysql.com/support/supportedplatforms/cluster.html>.

The NDB Cluster Auto-Installer is not supported with NDB 7.5.0 or 7.5.1 (Bug #79853, Bug #22502247).

**Supported Web browsers.** The Web-based installer is supported with recent versions of Firefox and Microsoft Internet Explorer. It should also work with recent versions of Opera, Safari, and Chrome, although we have not thoroughly tested for compatibility with these browsers.

**Required software—server.** The following software must be installed on the host where the Auto-Installer is run:

- **Python 2.6 or higher.** The Auto-Installer requires the Python interpreter and standard libraries. If these are not already installed on the system, you may be able to add them using the system's package manager. Otherwise, they can be downloaded from <http://python.org/download/>.
- **Paramiko 1.7.7.1 or higher.** You can download this from <http://www.lag.net/paramiko/> if it is not available from your system's package manager.
- **Pycrypto version 1.9 or higher.** This cryptography module is required by Paramiko. If it is not available using your system's package manager, you can download it from <https://www.dlitz.net/software/pycrypto/>.

All of the software in the preceding list is included in the Windows version of the configuration tool, and does not need to be installed separately.

**Required software—remote hosts.** The only software required for remote hosts where you wish to deploy NDB Cluster nodes is the SSH server, which is usually installed by default on Linux and Solaris systems. Several alternatives are available for Windows; for an overview of these, see [http://en.wikipedia.org/wiki/Comparison\\_of\\_SSH\\_servers](http://en.wikipedia.org/wiki/Comparison_of_SSH_servers).

An additional requirement when using multiple hosts is that it is possible to authenticate to any of the remote hosts using SSH and the proper keys or user credentials, as discussed in the next few paragraphs:

**Authentication and security.** Three basic security or authentication mechanisms for remote access are available to the Auto-Installer, which we list and describe here:

- **SSH.** A secure shell connection is used to enable the back end to perform actions on remote hosts. For this reason, an SSH server must be running on the remote host. In addition, the operating system user running the installer must have access to the remote server, either with a user name and password, or by using public and private keys.

#### Important

You should never use the system `root` account for remote access, as this is extremely insecure. In addition, `mysqld` cannot normally be started by system `root`. For these and other reasons, you should provide SSH credentials for a regular user account on the target system, and not for system `root`. For more information about this issue, see [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

- **HTTPS.** Remote communication between the Web browser front end and the back end is not encrypted by default, which means that information such as the user's SSH password is transmitted as cleartext that is readable to anyone. For communication from a remote client to be encrypted, the back end must have a certificate, and the front end must communicate with the back end using HTTPS rather than HTTP. Enabling HTTPS is accomplished most easily through issuing a self-signed certificate. Once the certificate is issued, you must make sure that it is used. You can do this by starting `ndb_setup.py` from the command line with the `--use-https` and `--cert-file` options.

- **Certificate-based authentication.** The back end `ndb_setup.py` process can execute commands on the local host as well as remote hosts. This means that anyone connecting to the back end can take charge of how commands are executed. To reject unwanted connections to the back end, a certificate may be required for authentication of the client. In this case, a certificate must be issued by the user, installed in the browser, and made available to the back end for authentication purposes. You can enact this requirement (together with or in place of password or key authentication) by starting `ndb_setup.py` with the `--ca-certs-file` option.

There is no need or requirement for secure authentication when the client browser is running on the same host as the Auto-Installer back end.

See also [Section 21.5.17, “NDB Cluster Security Issues”](#), which discusses security considerations to take into account when deploying NDB Cluster, as well as [Chapter 6, Security](#), for more general MySQL security information.

### 21.2.8.2 Using the NDB Cluster Auto-Installer

The NDB Cluster Auto-Installer consists of several pages, each corresponding to a step in the process used to configure and deploy an NDB Cluster, and listed here:

- **Welcome:** Begin using the Auto-Installer by choosing either to configure a new NDB Cluster, or to continue configuring an existing one.
- **Define Cluster:** Set basic information about the cluster as a whole, such as name, hosts, and load type. Here you can also set the SSH authentication type for accessing remote hosts, if needed.
- **Define Hosts:** Identify the hosts where you intend to run NDB Cluster processes.
- **Define Processes:** Assign one or more processes of a given type or types to each cluster host.
- **Define Attributes:** Set configuration attributes for processes or types of processes.
- **Deploy Cluster:** Deploy the cluster with the configuration set previously; start and stop the deployed cluster.

The following sections describe in greater detail the purpose and function of each of these pages, in the order just listed.

### Starting the NDB Cluster Auto-Installer

The Auto-Installer is provided together with the NDB Cluster software. (See [Section 21.2, “NDB Cluster Installation”](#).) The present section explains how to start the installer. You can do by invoking the `ndb_setup.py` executable.

#### Important

You should run the `ndb_setup.py` as a normal user; no special privileges are needed to do so. You should *not* run this program as the `mysql` user, or using the system `root` or Administrator account; doing so may cause the installation to fail.

`ndb_setup.py` is found in the `bin` within the NDB Cluster installation directory; a typical location might be `/usr/local/mysql/bin` on a Linux system or `C:\Program Files\MySQL\MySQL Server 5.6\bin` on a Windows system, but this can vary according to where the NDB Cluster software is installed on your system.

On Windows, you can also start the installer by running `setup.bat` in the NDB Cluster installation directory. When invoked from the command line, it accepts the same options as does `ndb_setup.py`.

`ndb_setup.py` can be started with any of several options that affect its operation, but it is usually sufficient to allow the default settings be used, in which case you can start `ndb_setup.py` by either of the following two methods:

1. Navigate to the NDB Cluster `bin` directory in a terminal and invoke it from the command line, without any additional arguments or options, like this:

```
shell> ndb_setup
```

This works regardless of operating platform.

2. Navigate to the NDB Cluster `bin` directory in a file browser (such Windows Explorer on Windows, or Konqueror, Dolphin, or Nautilus on Linux) and activate (usually by double-clicking) the `ndb_setup.py` file icon. This works on Windows, and should work with most common Linux desktops as well.

On Windows, you can also navigate to the NDB Cluster installation directory and activate the `setup.bat` file icon.

In either case, once `ndb_setup.py` is invoked, the Auto-Installer's **Welcome screen** should open in the system's default Web browser.

In some cases, you may wish to use non-default settings for the installer, such as specifying a different port for the Auto-Installer's included Web server to run on, in which case you must invoke `ndb_setup.py` with one or more startup options with values overriding the necessary defaults. The same startup options can be used on Windows systems with the `setup.bat` file supplied for such platforms in the NDB Cluster software distribution. This can be done using the command line, but if you want or need to start the installer from a desktop or file browser while employing one or more of these options, it is also possible to create a script or batch file containing the proper invocation, then to double-click its file icon in the file browser to start the installer. (On Linux systems, you might also need to make the script file executable first.) For information about advanced startup options for the NDB Cluster Auto-Installer, see [Section 21.4.27, “`ndb\_setup.py` — Start browser-based Auto-Installer for NDB Cluster \(DEPRECATED\)”](#).

## NDB Cluster Auto-Installer Welcome Screen

The **Welcome** screen is loaded in the default browser when `ndb_setup.py` is invoked, as shown here:

**Figure 21.7 The NDB Cluster Auto-Installer Welcome screen (Closeup)**

This screen provides the following two choices for entering the installer, one of which must be selected to continue:

1. **Create New NDB Cluster:** Start the Auto-Installer with a completely new cluster to be set up and deployed.
2. **Continue Previous Cluster Configuration:** Start the Auto-Installer at the same point where the previous session ended, with all previous settings preserved.

The second option requires that the browser be able to access its cookies from the previous session, as these provide the mechanism by which configuration and other information generated during a session is stored. In other words, to continue the previous session with the Auto-Installer, you must use the same web browser running on the same host as you did for the previous session.

## NDB Cluster Auto-Installer Define Cluster Screen

The **Define Cluster** screen is the first screen to appear following the choice made in the [Welcome screen](#), and is used for setting general properties of the cluster. The layout of the **Define Cluster** screen is shown here:

**Figure 21.8 The NDB Cluster Auto-Installer Define Cluster screen**

The **Define Cluster** screen allows you to set a number of general properties for the cluster, as described in this list:

- **Cluster name:** A name that identifies the cluster. The default is [MyCluster](#).
- **Host list:** A comma-delimited list of one or more hosts where cluster processes should run. By default, this is [127.0.0.1](#). If you add remote hosts to the list, you must be able to connect to them using the **SSH Credentials** supplied.
- **Application type:** Choose one of the following:
  1. **Simple testing:** Minimal resource usage for small-scale testing. This is the default. *Not intended for production environments.*
  2. **Web:** Maximize performance for the given hardware.
  3. **Real-time:** Maximize performance while maximizing sensitivity to timeouts in order to minimize the time needed to detect failed cluster processes.

- **Write load:** Choose a level for the anticipated number of writes for the cluster as a whole. You can choose any one of the following levels:
  1. **Low:** The expected load includes fewer than 100 write transactions for second.
  2. **Medium:** The expected load includes 100 to 1000 write transactions per second.
  3. **High:** The expected load includes more than 1000 write transactions per second.
- **SSH Credentials:** Choose **Key-Based SSH** or enter **User** and **Password** credentials. The SSH key or a user name with password is required for connecting to any remote hosts specified in the **Host list**. By default, **Key-Based SSH** is selected, and the **User** and **Password** fields are blank.

## NDB Cluster Auto-Installer Define Hosts Screen

The **Define Hosts** screen, shown here, provides a means of viewing and specifying several key properties of each cluster host:

**Figure 21.9 NDB Cluster Define Hosts screen**

The hosts currently entered are displayed in the grid with various pieces of information. You can add hosts by clicking the **Add hosts** button and entering a list of one or more comma-separated host names, IP addresses, or both (as when editing the host list on the [Define Cluster screen](#)).

Similarly, you can remove one or more hosts using the button labelled **Remove selected host(s)**. When you remove a host in this fashion, any process which was configured for that host is also removed.

If **Automatically get resource information for new hosts** is checked in the **Settings** menu, the Auto-Installer attempts to retrieve the platform name, amount of memory, and number of CPU cores and to fill these in automatically. The status of this is displayed in the *Resource info* column. Fetching the information from remote hosts is not instantaneous and may take some time, particularly from remote hosts running Windows.

If the SSH user credentials on the [Define Cluster screen](#) are changed, the tool tries to refresh the hardware information from any hosts for which information is missing. However, if a given field has already been edited, the user-supplied information is *not* overwritten by any value fetched from that host.

The hardware resource information, platform name, installation directory, and data directory can be edited by the user by clicking the corresponding cell in the grid, by selecting one or more hosts and clicking the button labelled **Edit selected host(s)**. This causes a dialog box to appear, in which these fields can be edited, as shown here:

**Figure 21.10 NDB Cluster Auto-Installer Edit Hosts dialog**

When more than one host is selected, any edited values are applied to all selected hosts.

## NDB Cluster Auto-Installer Define Processes Screen

The **Define Processes** screen, shown here, provides a way to assign NDB Cluster processes (nodes) to cluster hosts:

**Figure 21.11 NDB Cluster Auto-Installer Define Processes dialog**

This screen contains a process tree showing cluster hosts and processes set up to run on each one, as well as a panel which displays information about the item currently selected in the tree.

When this screen is accessed for the first time for a given cluster, a default set of processes is defined for you, based on the number of hosts. If you later return to the **Define Hosts** screen, remove all hosts, and add new hosts, this also causes a new default set of processes to be defined.

NDB Cluster processes are of the following types:

- **Management node.** Performs administrative tasks such as stopping individual data nodes, querying node and cluster status, and making backups. Executable: `ndb_mgmd`.
- **Single-threaded data node.** Stores data and executes queries. Executable: `ndbd`.

- **Multi threaded data node.** Stores data and executes queries with multiple worker threads executing in parallel. Executable: `ndbmttd`.
- **SQL node.** MySQL server for executing SQL queries against NDB. Executable: `mysqld`.
- **API node.** A client accessing data in NDB by means of the NDB API or other low-level client API, rather than by using SQL. See [MySQL NDB Cluster API Developer Guide](#), for more information.

For more information about process (node) types, see [Section 21.1.1, “NDB Cluster Core Concepts”](#).

Processes shown in the tree are numbered sequentially by type, for each host—for example, `SQL node 1`, `SQL node 2`, and so on—to simplify identification.

Each management node, data node, or SQL process must be assigned to a specific host, and is not allowed to run on any other host. An API node *may* be assigned to a single host, but this is not required. Instead, you can assign it to the special **Any host** entry which the tree also contains in addition to any other hosts, and which acts as a placeholder for processes that are allowed to run on any host. *Only API processes may use this Any host entry.*

**Adding processes.** To add a new process to a given host, either right-click that host's entry in the tree, then select the **Add process** popup when it appears, or select a host in the process tree, and press the **Add process** button below the process tree. Performing either of these actions opens the add process dialog, as shown here:

**Figure 21.12 NDB Cluster Auto-Installer Add Process Dialog**

Here you can select from among the available process types described earlier this section; you can also enter an arbitrary process name to take the place of the suggested value, if desired.

**Removing processes.** To delete a process, right-click on a process in the tree and select **delete process** from the pop up menu that appears, or select a process, then use the **delete process** button below the process tree.

When a process is selected in the process tree, information about that process is displayed in the information panel, where you can change the process name and possibly its type. *Important:* Currently, you can change a single-threaded data node (`ndbd`) to a multithreaded data node (`ndbmttd`), or the reverse, only; no other process type changes are allowed. If you want to make a change between any other process types, you must delete the original process first, then add a new process of the desired type.

## NDB Cluster Auto-Installer Define Attributes Screen

This screen has a layout similar to that of the [Define Processes screen](#), including a process tree. Unlike that screen's tree, the **Define Attributes** process tree is organized by process or node type, with

single-threaded and multithreaded data nodes considered to be of the same type for this purpose, in groups labelled **Management Layer**, **Data Layer**, **SQL Layer**, and **API Layer**. An information panel displays information regarding the item currently selected. The **Define Attributes** screen is shown here:

**Figure 21.13 NDB Cluster Auto-Installer Define Attributes screen**

The check box labelled **Show advanced configuration**, when checked, makes advanced options visible in the information pane. These options are set and used whether or not they are visible.

You can edit attributes for a single process by selecting that process from the tree, or for all processes of the same type in the cluster by selecting one of the **Layer** folders. A per-process value set for a given attribute overrides any per-group setting for that attribute that would otherwise apply to the process in question. An example of such an information panel (for an SQL process) is shown here:

**Figure 21.14 Define Attributes Detail With SQL Process Attributes**

| Process property              | Value                                          | Override |
|-------------------------------|------------------------------------------------|----------|
| Node identity and directories |                                                |          |
| NodeId [?]                    | 53                                             |          |
| HostName [?]                  | 127.0.0.1                                      |          |
| DataDir [?]                   | /export/home/tmp/mysql_cluster/S3/             |          |
| Communication                 |                                                |          |
| Port [?]                      | 3306                                           |          |
| Socket [?]                    | /export/home/tmp/mysql_cluster/S3/mysql.socket |          |

For some of the attributes shown in the information panel, a button bearing a plus sign is displayed, which means that the value of the attribute can be overridden. This button activates an input widget for the attribute, enabling you to change its value. When the value has been overridden, this button changes into a button showing an , as shown here:

**Figure 21.15 Define Attributes Detail, Overriding Attribute Default Value**

Clicking the **X** button next to an attribute undoes any changes made to it; it immediately reverts to the predefined value.

All configuration attributes have predefined values calculated by the installer, based such factors as host name, node ID, node type, and so on. In most cases, these values may be left as they are. If you are not familiar with it already, it is highly recommended that you read the applicable documentation before making changes to any of the attribute values. To make finding this information easier, each attribute name shown in the information panel is linked to its description in the online NDB Cluster documentation.

## NDB Cluster Auto-Installer Deploy Cluster Screen

This screen allows you to perform the following tasks:

- Review process startup commands and configuration files to be applied
- Distribute configuration files by creating any necessary files and directories on all cluster hosts—that is, *deploy* the cluster as presently configured
- Start and stop the cluster

The **Deploy Cluster** screen is shown here:

**Figure 21.16 NDB Cluster Auto-Installer Deploy Cluster Configuration screen**

Like the [Define Attributes screen](#), this screen features a process tree which is organized by process type. Next to each process in the tree is a status icon indicating the current status of the process: connected ([CONNECTED](#)), starting ([STARTING](#)), running ([STARTED](#)), stopping ([STOPPING](#)), or disconnected ([NO\\_CONTACT](#)). The icon shows green if the process is connected or running; yellow if it is starting or stopping; red if the process is stopped or cannot be contacted by the management server.

This screen also contains two information panels, one showing the startup command or commands needed to start the selected process. (For some processes, more than one command may be required—for example, if initialization is necessary.) The other panel shows the contents of the configuration file, if any, for the given process; currently, the management node process is the only type of process having a configuration file. Other process types are configured using command-line parameters when starting the process, or by obtaining configuration information from the management nodes as needed in real time.

This screen also contains three buttons, labelled as and performing the functions described in the following list:

- **Deploy cluster:** Verify that the configuration is valid. Create any directories required on the cluster hosts, and distribute the configuration files onto the hosts. A progress bar shows how far the deployment has proceeded.
- **Start cluster:** The cluster is deployed as with **Deploy cluster**, after which all cluster processes are started in the correct order.

Starting these processes may take some time. If the estimated time to completion is too large, the installer provides an opportunity to cancel or to continue of the startup procedure. A progress bar indicates the current status of the startup procedure, as shown here:

**Figure 21.17 Progress Bar With Status of Node Startup Process**

The process status icons adjoining the process tree mentioned previously also update with the status of each process.

- **Stop cluster:** After the cluster has been started, you can stop it using this. As with starting the cluster, cluster shutdown is not instantaneous, and may require some time complete. A progress bar, similar to that displayed during cluster startup, shows the approximate current status of the cluster shutdown procedure, as do the process status icons adjoining the process tree.

The Auto-Installer generates a `my.cnf` file containing the appropriate options for each `mysqld` process in the cluster.

## 21.2.9 The NDB Cluster Auto-Installer (NDB 7.6) (No longer supported)

### Note

This feature has been removed from NDB Cluster, and is no longer supported. See [Section 21.1.4, “What is New in NDB Cluster”](#), for more information.

This section describes the web-based graphical configuration installer included as part of the NDB Cluster 7.6 distribution. This version of the installer differs in many respects from that supplied with NDB 7.5 and earlier releases; if you are using NDB 7.5, see [Section 21.2.8, “The NDB Cluster Auto-Installer \(NDB 7.5\) \(No longer supported\)”](#), for relevant information. Some of the key improvements are listed here:

- Persistent storage in an encrypted file as an alternative to cookie-based storage, now used by default
- Secure (HTTPS) connections by default
- Upgraded Paramiko security library
- Ability to use passwords for encrypted private keys, and to use different credentials with different hosts
- Improved host information retrieval
- Improved configuration; advanced configuration parameters

See also [Section 21.1.4.2, “What is New in NDB Cluster 7.6”](#).

Topics discussed in the following sections include an overview of the installer and its parts, software and other requirements for running the installer, navigating the GUI, and using the installer to set up and start or stop an NDB Cluster on one or more host computers.

The NDB Cluster Auto-Installer is made up of two components. The front end is a GUI client implemented as a Web page that loads and runs in a standard Web browser such as Firefox or Microsoft Internet Explorer. The back end is a server process (`ndb_setup.py`) that runs on the local machine or on another host to which you have access.

These two components (client and server) communicate with each other using standard HTTP requests and responses. The back end can manage NDB Cluster software programs on any host where the back end user has granted access. If the NDB Cluster software is on a different host, the back end relies on SSH for access, using the Paramiko library for executing commands remotely (see [Section 21.2.9.1, “NDB Cluster Auto-Installer Requirements”](#)).

### 21.2.9.1 NDB Cluster Auto-Installer Requirements

This section provides information on supported operating platforms and software, required software, and other prerequisites for running the NDB Cluster Auto-Installer.

**Supported platforms.** The NDB Cluster Auto-Installer is available with NDB 8.0 distributions for recent versions of Linux, Windows, Solaris, and macOS. For more detailed information about platform support for NDB Cluster and the NDB Cluster Auto-Installer, see <https://www.mysql.com/support/supportedplatforms/cluster.html>.

**Supported web browsers.** The web-based installer is supported with recent versions of Firefox and Microsoft Internet Explorer. It should also work with recent versions of Opera, Safari, and Chrome, although we have not thoroughly tested for compatibility with these browsers.

**Required software—server.** The following software must be installed on the host where the Auto-Installer is run:

- **Python 2.6 or higher.** The Auto-Installer requires the Python interpreter and standard libraries. If these are not already installed on the system, you may be able to add them using the system's package manager. Otherwise, you can download them from <http://python.org/download/>.
- **Paramiko 2 or higher.** This is required to communicate with remote hosts using SSH. You can download it from <http://www.lag.net/paramiko/>. Paramiko may also be available from your system's package manager.
- **Pycrypto version 2.6 or higher.** This cryptography module is required by Paramiko, and can be uninstalled using `pip install cryptography`. If `pip` is not installed, and the module is not available using your system's package manager, you can download it from <https://www.dlitz.net/software/pycrypto/>.

All of the software in the preceding list is included in the Windows version of the configuration tool, and does not need to be installed separately.

The Paramiko and Pycrypto libraries are required only if you intend to deploy NDB Cluster nodes on remote hosts, and are not needed if all nodes are on the same host where the installer is run.

**Required software—remote hosts.** The only software required for remote hosts where you wish to deploy NDB Cluster nodes is the SSH server, which is usually installed by default on Linux and Solaris systems. Several alternatives are available for Windows; for an overview of these, see [http://en.wikipedia.org/wiki/Comparison\\_of\\_SSH\\_servers](http://en.wikipedia.org/wiki/Comparison_of_SSH_servers).

An additional requirement when using multiple hosts is that it is possible to authenticate to any of the remote hosts using SSH and the proper keys or user credentials, as discussed in the next few paragraphs:

**Authentication and security.** Three basic security or authentication mechanisms for remote access are available to the Auto-Installer, which we list and describe here:

- **SSH.** A secure shell connection is used to enable the back end to perform actions on remote hosts. For this reason, an SSH server must be running on the remote host. In addition, the operating system user running the installer must have access to the remote server, either with a user name and password, or by using public and private keys.

#### Important

You should never use the system `root` account for remote access, as this is extremely insecure. In addition, `mysqld` cannot normally be started by system `root`. For these and other reasons, you should provide SSH credentials for a regular user account on the target system, and not for system `root`. For more information about this issue, see [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

- **HTTPS.** Remote communication between the Web browser front end and the back end is not encrypted by default, which means that information such as the user's SSH password is transmitted as cleartext that is readable to anyone. For communication from a remote client to be encrypted,

the back end must have a certificate, and the front end must communicate with the back end using HTTPS rather than HTTP. Enabling HTTPS is accomplished most easily through issuing a self-signed certificate. Once the certificate is issued, you must make sure that it is used. You can do this by starting `ndb_setup.py` from the command line with the `--use-https (-S)` and `--cert-file (-c)` options.

A sample certificate file `cfg.pem` is included and is used by default. This file is located in the `mcc` directory under the installation share directory; on Linux, the full path to the file is normally `/usr/share/mysql/mcc/cfg.pem`. On Windows systems, this is usually `C:\Program Files\MySQL\MySQL Server 5.7\share\mcc\cfg.pem`. Letting the default be used means that, for testing purposes, you can simply start the installer with the `-S` option to use an HTTPS connection between the browser and the back end.

The Auto-Installer saves the configuration file for a given cluster `mycluster01` as `mycluster01.mcc` in the home directory of the user invoking the `ndb_setup.py` executable. This file is encrypted with a passphrase supplied by the user (using [Fernet](#)); because HTTP transmits the passphrase in the clear, *it is strongly recommended that you always use an HTTPS connection to access the Auto-Installer on a remote host*.

- **Certificate-based authentication.** The back end `ndb_setup.py` process can execute commands on the local host as well as remote hosts. This means that anyone connecting to the back end can take charge of how commands are executed. To reject unwanted connections to the back end, a certificate may be required for authentication of the client. In this case, a certificate must be issued by the user, installed in the browser, and made available to the back end for authentication purposes. You can enact this requirement (together with or in place of password or key authentication) by starting `ndb_setup.py` with the `--ca-certs-file (-a)` option.

There is no need or requirement for secure authentication when the client browser is running on the same host as the Auto-Installer back end.

See also [Section 21.5.17, “NDB Cluster Security Issues”](#), which discusses security considerations to take into account when deploying NDB Cluster, as well as [Chapter 6, Security](#), for more general MySQL security information.

### 21.2.9.2 Using the NDB Cluster Auto-Installer

The NDB Cluster Auto-Installer interface is made up of several pages, each corresponding to a step in the process used to configure and deploy an NDB Cluster. These pages are listed here, in order:

- **Welcome:** Begin using the Auto-Installer by choosing either to configure a new NDB Cluster, or to continue configuring an existing one.
- **Define Cluster:** Set basic information about the cluster as a whole, such as name, hosts, and load type. Here you can also set the SSH authentication type for accessing remote hosts, if needed.
- **Define Hosts:** Identify the hosts where you intend to run NDB Cluster processes.
- **Define Processes:** Assign one or more processes of a given type or types to each cluster host.
- **Define Parameters:** Set configuration attributes for processes or types of processes.
- **Deploy Configuration:** Deploy the cluster with the configuration set previously; start and stop the deployed cluster.

### NDB Cluster Installer Settings and Help Menus

These menus are shown on all screens except for the **Welcome** screen. They provide access to installer settings and information. The **Settings** menu is shown here in more detail:

**Figure 21.18 NDB Cluster Auto-Installer Settings menu**

The **Settings** menu has the following entries:

- **Automatically save configuration as cookies:** Save your configuration information—such as host names, process data, and parameter values—as a cookie in the browser. When this option is chosen, all information except any SSH password is saved. This means that you can quit and restart the browser, and continue working on the same configuration from where you left off at the end of the previous session. This option is enabled by default.

The SSH password is never saved; if you use one, you must supply it at the beginning of each new session.

- **Show advanced configuration options:** Shows by default advanced configuration parameters where available.

Once set, the advanced parameters continue to be used in the configuration file until they are explicitly changed or reset. This is regardless of whether the advanced parameters are currently visible in the installer; in other words, disabling the menu item does not reset the values of any of these parameters.

You can also toggle the display of advanced parameters for individual processes on the [Define Parameters screen](#).

This option is disabled by default.

- **Automatically get resource information for new hosts:** Query new hosts automatically for hardware resource information to pre-populate a number of configuration options and values. In this case, the suggested values are not mandatory, but they are used unless explicitly changed using the appropriate editing options in the installer.

This option is enabled by default.

The installer **Help** menu is shown here:

**Figure 21.19 NDB Cluster Auto-Installer Help menu**

The **Help** menu provides several options, described in the following list:

- **Contents:** Show the built-in user guide. This is opened in a separate browser window, so that it can be used simultaneously with the installer without interrupting workflow.
- **Current page:** Open the built-in user guide to the section describing the page currently displayed in the installer.
- **About:** open a dialog displaying the installer name and the version number of the NDB Cluster distribution with which it was supplied.

The Auto-Installer also provides context-sensitive help in the form of tooltips for most input widgets.

In addition, the names of most NDB configuration parameters are linked to their descriptions in the online documentation. The documentation is displayed in a separate browser window.

The next section discusses starting the Auto-Installer. The sections immediately following it describe in greater detail the purpose and function of each of these pages in the order listed previously.

## Starting the NDB Cluster Auto-Installer

The Auto-Installer is provided together with the NDB Cluster software. Separate RPM and .deb packages containing only the Auto-Installer are also available for many Linux distributions. (See [Section 21.2, “NDB Cluster Installation”](#).)

The present section explains how to start the installer. You can do by invoking the `ndb_setup.py` executable.

### User and privileges

You should run the `ndb_setup.py` as a normal user; no special privileges are needed to do so. You should *not* run this program as the `mysql` user, or using the system `root` or Administrator account; doing so may cause the installation to fail.

`ndb_setup.py` is found in the `bin` within the NDB Cluster installation directory; a typical location might be `/usr/local/mysql/bin` on a Linux system or `C:\Program Files\MySQL\MySQL Server 5.7\bin` on a Windows system. This can vary according to where the NDB Cluster software is installed on your system, and the installation method.

On Windows, you can also start the installer by running `setup.bat` in the NDB Cluster installation directory. When invoked from the command line, this batch file accepts the same options as `ndb_setup.py`.

`ndb_setup.py` can be started with any of several options that affect its operation, but it is usually sufficient to allow the default settings be used, in which case you can start `ndb_setup.py` by either of the following two methods:

1. Navigate to the NDB Cluster `bin` directory in a terminal and invoke it from the command line, without any additional arguments or options, like this:

```
shell> ndb_setup.py
Running out of install dir: /usr/local/mysql/bin
Starting web server on port 8081
URL is https://localhost:8081/welcome.html
deathkey=627876
Press CTRL+C to stop web server.
The application should now be running in your browser.
(Alternatively you can navigate to https://localhost:8081/welcome.html to start it)
```

This works regardless of operating platform.

2. Navigate to the NDB Cluster `bin` directory in a file browser (such as Windows Explorer on Windows, or Konqueror, Dolphin, or Nautilus on Linux) and activate (usually by double-clicking) the `ndb_setup.py` file icon. This works on Windows, and should work with most common Linux desktops as well.

On Windows, you can also navigate to the NDB Cluster installation directory and activate the `setup.bat` file icon.

In either case, once `ndb_setup.py` is invoked, the Auto-Installer's **Welcome screen** should open in the system's default web browser. If not, you should be able to open the page `http://localhost:8081/welcome.html` or `https://localhost:8081/welcome.html` manually in the browser.

In some cases, you may wish to use non-default settings for the installer, such as specifying HTTPS for connections, or a different port for the Auto-Installer's included web server to run on, in which case you must invoke `ndb_setup.py` with one or more startup options with values overriding the necessary defaults. The same startup options can be used on Windows systems with the `setup.bat` file supplied for such platforms in the NDB Cluster software distribution. This can be done using the command line, but if you want or need to start the installer from a desktop or file browser while employing one or more of these options, it is also possible to create a script or batch file containing the proper invocation, then to double-click its file icon in the file browser to start the installer. (On Linux systems, you might also need to make the script file executable first.) If you plan to use the Auto-Installer from a remote host, you should start using the `-S` option. For information about this and other advanced startup options for the NDB Cluster Auto-Installer, see [Section 21.4.27, “`ndb\_setup.py` — Start browser-based Auto-Installer for NDB Cluster \(DEPRECATED\)”](#).

## NDB Cluster Auto-Installer Welcome Screen

The **Welcome** screen is loaded in the default browser when `ndb_setup.py` is invoked. The first time the Auto-Installer is run (or if for some other reason there are no existing configurations), this screen appears as shown here:

**Figure 21.20** The NDB Cluster Auto-Installer Welcome screen, first run

In this case, the only choice of cluster listed is for configuration of a new cluster, and both the **View Cfg** and **Continue** buttons are inactive.

To create a new configuration, enter and confirm a passphrase in the text boxes provided. When this has been done, you can click **Continue** to proceed to the **Define Cluster** screen where you can assign a name to the new cluster.

If you have previously created one or more clusters with the Auto-Installer, they are listed by name. This example shows an existing cluster named `mycluster-1`:

**Figure 21.21** The NDB Cluster Auto-Installer Welcome screen, with previously created cluster `mycluster-1`

To view the configuration for and work with a given cluster, select the radiobutton next to its name in the list, then enter and confirm the passphrase that was used to create it. When you have done this correctly, you can click **View Cfg** to view and edit this cluster's configuration.

## NDB Cluster Auto-Installer Define Cluster Screen

The **Define Cluster** screen appears following the [Welcome screen](#), and is used for setting general properties of the cluster. The layout of the **Define Cluster** screen is shown here:

**Figure 21.22 The NDB Cluster Auto-Installer Define Cluster screen**

This screen and subsequent screens also include **Settings** and **Help** menus which are described later in this section; see [NDB Cluster Installer Settings and Help Menus](#).

The **Define Cluster** screen allows you to set three sorts of properties for the cluster: cluster properties, SSH properties, and installation properties.

Cluster properties that can be set on this screen are listed here:

- **Cluster name:** A name that identifies the cluster; in this example, this is `mycluster-1`. The name is set on the previous screen and cannot be changed here.
- **Host list:** A comma-delimited list of one or more hosts where cluster processes should run. By default, this is `127.0.0.1`. If you add remote hosts to the list, you must be able to connect to them using the credentials supplied as SSH properties.
- **Application type:** Choose one of the following:
  1. **Simple testing:** Minimal resource usage for small-scale testing. This is the default. *Not intended for production environments.*
  2. **Web:** Maximize performance for the given hardware.
  3. **Real-time:** Maximize performance while maximizing sensitivity to timeouts in order to minimize the time needed to detect failed cluster processes.
- **Write load:** Choose a level for the anticipated number of writes for the cluster as a whole. You can choose any one of the following levels:

1. **Low**: The expected load includes fewer than 100 write transactions for second.
2. **Medium**: The expected load includes 100 to 1000 write transactions per second; this is the default.
3. **High**: The expected load includes more than 1000 write transactions per second.

SSH properties are described in the following list:

- **Key-Based SSH**: Check this box to use key-enabled login to the remote host. If checked, the key user and passphrase must also be supplied; otherwise, a user and password for a remote login account are needed.
- **User**: Name of user with remote login access.
- **Password**: Password for remote user.
- **Key user**: Name of the user for whom the key is valid, if not the same as the operating system user.
- **Key passphrase**: Passphrase for the key, if required.
- **Key file**: Path to the key file. The default is `~/.ssh/id_rsa`.

The SSH properties set on this page apply to all hosts in the cluster. They can be overridden for a given host by editing that host's properties on the **Define Hosts** screen.

Two installation properties can also be set on this screen:

- **Install MySQL Cluster**: This setting determines the source from which the Auto-Installer installs NDB Cluster software, if any, on the cluster hosts. Possible values and their effects are listed here:
  1. **DOCKER**: Try to install the MySQL Cluster Docker image from <https://hub.docker.com/r/mysql/mysql-cluster/> on each host
  2. **REPO**: Try to install the NDB Cluster software from the [MySQL Repositories](#) on each host
  3. **BOTH**: Try to install either the Docker image or the software from the repository on each host, giving preference to the repository
  4. **NONE**: Do not install the NDB Cluster software on the hosts; this is the default
- **Open FW Ports**: Check this check box to have the installer attempt to open ports required by NDB Cluster processes on all hosts.

The next figure shows the **Define Cluster** page with settings for a small test cluster with all nodes running on `localhost`:

**Figure 21.23 The NDB Cluster Auto-Installer Define Cluster screen, with settings for a test cluster**

After making the desired settings, you can save them to the configuration file and proceed to the **Define Hosts** screen by clicking the **Save & Next** button.

If you exit the installer without saving, no changes are made to the configuration file.

## NDB Cluster Auto-Installer Define Hosts Screen

The **Define Hosts** screen, shown here, provides a means of viewing and specifying several key properties of each cluster host:

**Figure 21.24 NDB Cluster Define Hosts screen, start**

Properties shown include the following:

- **Host:** Name or IP address of this host
- **Res.info:** Shows [OK](#) if the installer was able to retrieve requested resource information from this host
- **Platform:** Operating system or platform
- **Memory (MB):** Amount of RAM on this host
- **Cores:** Number of CPU cores available on this host
- **MySQL Cluster install directory:** Path to directory where the NDB Cluster software is installed on this host; defaults to [/usr/local/bin](#)
- **MySQL Cluster data directory:** Path to directory used for data by NDB Cluster processes on this host; defaults to [/var/lib/mysql-cluster](#).
- **DiskFree:** Free disk space in bytes

For hosts with multiple disks, only the space available on the disk used for the data directory is shown.

This screen also provides an extended view for each host that includes the following properties:

- **FDQN:** This host's fully qualified domain name, used by the installer to connect with it, distribute configuration information to it, and start and stop cluster processes on it.
- **Internal IP:** The IP address used for communication with cluster processes running on this host by processes running elsewhere.
- **OS Details:** Detailed operating system name and version information.
- **Open FW:** If this check box is enabled, the installer attempts to open ports in the host's firewall needed by cluster processes.
- **REPO URL:** URL for MySQL NDB Cluster repository
- **DOCKER URL:** URL for MySQL NDB CLuster Docker images; for NDB 8.0, this is [mysql/mysql-cluster:8.0](#).
- **Install:** If this check box is enabled, the Auto-Installer attempts to install the NDB Cluster software on this host

The extended view is shown here:

**Figure 21.25 NDB Cluster Define Hosts screen, extended host info view**

The screenshot shows the 'Define hosts' screen of the MySQL Cluster Installer. At the top, there's a navigation bar with 'Define cluster > Define hosts > Define processes > Define parameters > Deploy configuration'. Below the navigation is a section titled 'Select and Edit Hosts' with a detailed description of how it works. The main area is a table with columns: Host, Res.info, Platform, Memory (MB), Cores, MySQL Cluster install directory, MySQL Cluster data directory, and DiskFree. There are two rows: one for 'localhost' with 'OK' status and another for 'localhost' with 'opensuse, ver. 42.3' status. Buttons at the bottom include 'Add host', 'Remove selected host(s)', 'Edit selected host', 'Refresh selected host(s)', 'Hide extended info', and navigation buttons for 'Previous', 'Save&Next', and 'Finish'.

| Host      | Res.info    | Platform            | Memory (MB) | Cores    | MySQL Cluster install directory | MySQL Cluster data directory | DiskFree |
|-----------|-------------|---------------------|-------------|----------|---------------------------------|------------------------------|----------|
| FQDN      | Internal IP | OS details          | Open FW     | REPO URL | DOCKER URL                      | Install                      |          |
| localhost | OK          | Linux               | 32032       | 8        | /usr/local/bin/                 | /var/lib/mysql-cluster/      | 550G     |
| localhost | localhost   | opensuse, ver. 42.3 |             |          |                                 |                              |          |

All cells in the display are editable, with the exceptions of those in the **Host**, **Res.info**, and **FQDN** columns.

Be aware that it may take some time for information to be retrieved from remote hosts. Fields for which no value could be retrieved are indicated with an ellipsis (...). You can retry the fetching of resource information from one or more hosts by selecting the hosts in the list and then clicking the **Refresh selected host(s)** button.

### Adding and Removing Hosts

You can add one or more hosts by clicking the **Add Host** button and entering the required properties where indicated in the **Add new host** dialog, shown here:

Figure 21.26 NDB Cluster Add Host dialog

This dialog includes the following fields:

- **Host name:** A comma-separated list of one or more host names, IP addresses, or both. These must be accessible from the host where the Auto-Installer is running.
- **Host internal IP (VPN):** If you are setting up the cluster to run on a VPN or other internal network, enter the IP address or addresses used for contact by cluster nodes on other hosts.

- **Key-based auth:** If checked, enables key-based authentication. You can enter any additional needed information in the **User**, **Passphrase**, and **Key file** fields.
- **Ordinary login:** If accessing this host using a password-based login, enter the appropriate information in the **User** and **Password** fields.
- **Open FW ports:** Selecting this check box allows the installer try opening any ports needed by cluster processes in this host's firewall.
- **Configure installation:** Checking this allows the Auto-Install to attempt to set up the NDB Cluster software on this host.

To save the new host and its properties, click **Add**. If you wish to cancel without saving any changes, click **Cancel** instead.

Similarly, you can remove one or more hosts using the button labelled **Remove selected host(s)**. *When you remove a host, any process which was configured for that host is also removed.*

### Warning

**Remove selected host(s)** acts immediately. There is no confirmation dialog. If you remove a host in error, you must re-enter its name and properties manually using **Add host**.

If the SSH user credentials on the [Define Cluster screen](#) are changed, the Auto-Installer attempts to refresh the resource information from any hosts for which information is missing.

You can edit the host's platform name, hardware resource information, installation directory, and data directory by clicking the corresponding cell in the grid, by selecting one or more hosts and clicking the button labelled **Edit selected host(s)**. This causes a dialog box to appear, in which these fields can be edited, as shown here:

**Figure 21.27 NDB Cluster Auto-Installer Edit Hosts dialog**

| Platform | Memory (MB) | CPU cores [?] | MySQL Cluster install directory | MySQL Cluster data directory | DiskFree [?] |
|----------|-------------|---------------|---------------------------------|------------------------------|--------------|
| Linux    | 32,032      | 8             |                                 |                              | 550G         |

Host external IP: [?]

Host internal IP (VPN): [?]

Key-based auth: [?]

User [?]   
Passphrase [?]

Key file [?]

Ordinary login:  
User [?]  Password [?]

Open FW ports [?]  Configure installation [?]

When more than one host is selected, any edited values are applied to all selected hosts.

Once you have entered all desired host information, you can use the **Save & Next** button to save the information to the cluster's configuration file and proceed to the **Define Processes** screen, where you can set up NDB Cluster processes on one or more hosts.

## NDB Cluster Auto-Installer Define Processes Screen

The **Define Processes** screen, shown here, provides a way to assign NDB Cluster processes (nodes) to cluster hosts:

**Figure 21.28 NDB Cluster Auto-Installer Define Processes dialog**

This screen contains a process tree showing cluster hosts and processes set up to run on each one, as well as a panel which displays information about the item currently selected in the tree.

When this screen is accessed for the first time for a given cluster, a default set of processes is defined for you, based on the number of hosts. If you later return to the **Define Hosts** screen, remove all hosts, and add new hosts, this also causes a new default set of processes to be defined.

NDB Cluster processes are of the types described in this list:

- **Management node.** Performs administrative tasks such as stopping individual data nodes, querying node and cluster status, and making backups. Executable: `ndb_mgmd`.
- **Single-threaded data node.** Stores data and executes queries. Executable: `ndbd`.
- **Multi threaded data node.** Stores data and executes queries with multiple worker threads executing in parallel. Executable: `ndbmtd`.
- **SQL node.** MySQL server for executing SQL queries against NDB. Executable: `mysqld`.
- **API node.** A client accessing data in NDB by means of the NDB API or other low-level client API, rather than by using SQL. See [MySQL NDB Cluster API Developer Guide](#), for more information.

For more information about process (node) types, see [Section 21.1.1, “NDB Cluster Core Concepts”](#).

Processes shown in the tree are numbered sequentially by type, for each host—for example, `SQL node 1`, `SQL node 2`, and so on—to simplify identification.

Each management node, data node, or SQL process must be assigned to a specific host, and is not allowed to run on any other host. An API node *may* be assigned to a single host, but this is not required. Instead, you can assign it to the special **Any host** entry which the tree also contains in addition to any other hosts, and which acts as a placeholder for processes that are allowed to run on any host. *Only API processes may use this Any host entry.*

**Adding processes.** To add a new process to a given host, either right-click that host's entry in the tree, then select the **Add process** popup when it appears, or select a host in the process tree, and press the **Add process** button below the process tree. Performing either of these actions opens the add process dialog, as shown here:

Figure 21.29 NDB Cluster Auto-Installer Add Process Dialog

Here you can select from among the available process types described earlier this section; you can also enter an arbitrary process name to take the place of the suggested value, if desired.

**Removing processes.** To delete a process, select that process in the tree and use the **Del process** button.

When you select a process in the process tree, information about that process is displayed in the information panel, where you can change the process name and possibly its type. You can change a multi-threaded data node (`ndbmtd`) to a single-threaded data node (`ndbd`), or the reverse, only; no other process type changes are allowed. *If you want to make a change between any other process types, you must delete the original process first, then add a new process of the desired type.*

## NDB Cluster Auto-Installer Define Parameters Screen

Like the **Define Processes** screen, this screen includes a process tree; the **Define Parameters** process tree is organized by process or node type, in groups labelled **Management Layer**, **Data Layer**, **SQL Layer**, and **API Layer**. An information panel displays information regarding the item currently selected. The **Define Attributes** screen is shown here:

**Figure 21.30 NDB Cluster Auto-Installer Define Parameters screen**

The check box labelled **Show advanced configuration**, when checked, makes advanced options for data node and SQL node processes visible in the information pane. These options are set and used whether or not they are visible. You can also enable this behavior globally by checking **Show advanced configuration options** under **Settings** (see [NDB Cluster Installer Settings and Help Menus](#)).

You can edit attributes for a single process by selecting that process from the tree, or for all processes of the same type in the cluster by selecting one of the **Layer** folders. A per-process value set for a given attribute overrides any per-group setting for that attribute that would otherwise apply to the process in question. An example of such an information panel (for an SQL process) is shown here:

**Figure 21.31 Define Parameters—Process Attributes**

Attributes whose values can be overridden are shown in the information panel with a button bearing a plus sign. This + button activates an input widget for the attribute, enabling you to change its value. When the value has been overridden, this button changes into a button showing an X. The X button undoes any changes made to a given attribute, which immediately reverts to the predefined value.

All configuration attributes have predefined values calculated by the installer, based such factors as host name, node ID, node type, and so on. In most cases, these values may be left as they are. If you are not familiar with it already, it is highly recommended that you read the applicable documentation before making changes to any of the attribute values. To make finding this information easier, each attribute name shown in the information panel is linked to its description in the online NDB Cluster documentation.

## NDB Cluster Auto-Installer Deploy Configuration Screen

This screen allows you to perform the following tasks:

- Review process startup commands and configuration files to be applied
- Distribute configuration files by creating any necessary files and directories on all cluster hosts—that is, *deploy* the cluster as presently configured
- Start and stop the cluster

The **Deploy Configuration** screen is shown here:

**Figure 21.32 NDB Cluster Auto-Installer Deploy Configuration screen**

Like the [Define Parameters screen](#), this screen features a process tree which is organized by process type. Next to each process in the tree is a status icon indicating the current status of the process: connected ([CONNECTED](#)), starting ([STARTING](#)), running ([STARTED](#)), stopping ([STOPPING](#)), or disconnected ([NO\\_CONTACT](#)). The icon shows green if the process is connected or running; yellow if it is starting or stopping; red if the process is stopped or cannot be contacted by the management server.

This screen also contains two information panels, one showing the startup command or commands needed to start the selected process. (For some processes, more than one command may be required—for example, if initialization is necessary.) The other panel shows the contents of the configuration file, if any, for the given process.

This screen also contains four buttons, labelled as and performing the functions described in the following list:

- **Install cluster:** Nonfunctional in this release; implementation intended for a future release.
- **Deploy cluster:** Verify that the configuration is valid. Create any directories required on the cluster hosts, and distribute the configuration files onto the hosts. A progress bar shows how far the deployment has proceeded, as shown here, and a dialog is displayed when the deployment has completed, as shown here:

**Figure 21.33 Cluster Deployment Process**

## The NDB Cluster Auto-Installer (NDB 7.6) (No longer supported)

- **Start cluster:** The cluster is deployed as with **Deploy cluster**, after which all cluster processes are started in the correct order.

Starting these processes may take some time. If the estimated time to completion is too large, the installer provides an opportunity to cancel or to continue of the startup procedure. A progress bar indicates the current status of the startup procedure, as shown here:

**Figure 21.34 Cluster Startup Process with Progress Bar**

The process status icons next to the items shown in the process tree also update with the status of each process.

A confirmation dialog is shown when the startup process has completed, as shown here:

**Figure 21.35 Cluster Startup, Process Completed Dialog**

- **Stop cluster:** After the cluster has been started, you can stop it using this. As with starting the cluster, cluster shutdown is not instantaneous, and may require some time complete. A progress bar, similar to that displayed during cluster startup, shows the approximate current status of the cluster

shutdown procedure, as do the process status icons adjoining the process tree. The progress bar is shown here:

**Figure 21.36 Cluster Shutdown Process, with Progress Bar**

A confirmation dialog indicates when the shutdown process is complete:

**Figure 21.37 Cluster Shutdown, Process Completed Dialog**

The Auto-Installer generates a `config.ini` file containing NDB node parameters for each management node, as well as a `my.cnf` file containing the appropriate options for each `mysqld` process in the cluster. No configuration files are created for data nodes or API nodes.

## 21.3 Configuration of NDB Cluster

A MySQL server that is part of an NDB Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the `NDB` storage engine. This engine is also referred to sometimes as `NDBCLOUDER`, although `NDB` is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the `NDB` storage engine disabled. To enable `NDB`, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on `localhost`. However, should you need to specify that its location is elsewhere, this can be

done in `my.cnf`, or with the `mysql` client. Before the `NDB` storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about `--ndbcluster` and other `mysqld` options specific to NDB Cluster, see [MySQL Server Options for NDB Cluster](#).

For general information about installing NDB Cluster, see [Section 21.2, “NDB Cluster Installation”](#).

### 21.3.1 Quick Test Setup of NDB Cluster

To familiarize you with the basics, we describe the simplest possible configuration for a functional NDB Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```
file "config.ini" - showing minimal setup consisting of 1 data node,
1 management server, and 3 MySQL servers.
The empty default sections are not required, and are shown only for
the sake of completeness.
Data nodes must provide a hostname but MySQL Servers are not required
to do so.
If you don't know the hostname for your machine, use localhost.
The DataDir parameter also has a default value, but it is recommended to
set it explicitly.
Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

By default, `ndbd` looks for the management server at `localhost` on port 1186.

**Note**

If you have installed MySQL from a binary tarball, you must specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these can be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysql_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.7.34

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
***** 12. row *****
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

```
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
***** 1. row *****
 Table: ctest
Create Table: CREATE TABLE `ctest` (
 `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
```

```

Cluster Configuration

[ndbd(NDB)] 1 node(s)
id=2 @127.0.0.1 (Version: 5.7.33-ndb-7.5.23, Nodegroup: 0, *)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @127.0.0.1 (Version: 5.7.33-ndb-7.5.23)

[mysqld(API)] 3 node(s)
id=3 @127.0.0.1 (Version: 5.7.33-ndb-7.5.23)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)

```

At this point, you have successfully set up a working NDB Cluster . You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

### 21.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables

The next several sections provide summary tables of NDB Cluster node configuration parameters used in the `config.ini` file to govern various aspects of node behavior, as well as of options and variables read by `mysqld` from a `my.cnf` file or from the command line when run as an NDB Cluster process. Each of the node parameter tables lists the parameters for a given type (`ndbd`, `ndb_mgmd`, `mysqld`, `computer`, `tcp`, or `shm`). All tables include the data type for the parameter, option, or variable, as well as its default, minimum, and maximum values as applicable.

**Considerations when restarting nodes.** For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked as `node` online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

#### Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes`. In addition, it is the generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

**Note**

[4294967039](#) often appears as a maximum value in these tables. This value is defined in the `NDBCLUSTER` sources as `MAX_INT_RNIL` and is equal to `0xFFFFFEFF`, or  $2^{32} - 2^8 - 1$ .

### 21.3.2.1 NDB Cluster Data Node Configuration Parameters

The listings in this section provide information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring NDB Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 21.3.3.6, "Defining NDB Cluster Data Nodes"](#).

These parameters also apply to `ndbmttd`, the multithreaded version of `ndbd`. A separate listing of parameters specific to `ndbmttd` follows.

- [Arbitration](#): How arbitration should be performed to avoid split-brain issues in event of node failure.
- [ArbitrationTimeout](#): Maximum time (milliseconds) database partition waits for arbitration signal.
- [BackupDataBufferSize](#): Default size of databuffer for backup (in bytes).
- [BackupDataDir](#): Path to where to store backups. Note that string '/BACKUP' is always appended to this setting, so that \*effective\* default is `FileSystemPath/BACKUP`.
- [BackupDiskWriteSpeedPct](#): Sets percentage of data node's allocated maximum write speed (`MaxDiskWriteSpeed`) to reserve for LCPs when starting backup.
- [BackupLogBufferSize](#): Default size of log buffer for backup (in bytes).
- [BackupMaxWriteSize](#): Maximum size of file system writes made by backup (in bytes).
- [BackupMemory](#): Total memory allocated for backups per node (in bytes).
- [BackupReportFrequency](#): Frequency of backup status reports during backup in seconds.
- [BackupWriteSize](#): Default size of file system writes made by backup (in bytes).
- [BatchSizePerLocalScan](#): Used to calculate number of lock records for scan with hold lock.
- [BuildIndexThreads](#): Number of threads to use for building ordered indexes during system or node restart. Also applies when running `ndb_restore --rebuild-indexes`. Setting this parameter to 0 disables multithreaded building of ordered indexes.
- [CompressedBackup](#): Use zlib to compress backups as they are written.
- [CompressedLCP](#): Write compressed LCPs using zlib.
- [ConnectCheckIntervalDelay](#): Time between data node connectivity check stages. Data node is considered suspect after 1 interval and dead after 2 intervals with no response.
- [CrashOnCorruptedTuple](#): When enabled, forces node to shut down whenever it detects corrupted tuple.
- [DataDir](#): Data directory for this node.
- [DataMemory](#): Number of bytes on each data node allocated for storing data; subject to available system RAM and size of `IndexMemory`.
- [DefaultHashMapSize](#): Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840..
- [DictTrace](#): Enable DBDICT debugging; for NDB development.

- `DiskIOThreadPool`: Number of unbound threads for file access, applies to disk data only.
- `Diskless`: Run without using disk.
- `DiskPageBufferEntries`: Memory to allocate in DiskPageBufferMemory; very large disk transactions may require increasing this value.
- `DiskPageBufferMemory`: Number of bytes on each data node allocated for disk page buffer cache.
- `DiskSyncSize`: Amount of data written to file before synch is forced.
- `EnablePartialLcp`: Enable partial LCP (true); if this is disabled (false), all LCPs write full checkpoints.
- `EnableRedoControl`: Enable adaptive checkpointing speed for controlling redo log usage.
- `EventLogBufferSize`: Size of circular buffer for NDB log events within data nodes.
- `ExecuteOnComputer`: String referencing earlier defined COMPUTER.
- `ExtraSendBufferMemory`: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- `FileSystemPath`: Path to directory where data node stores its data (directory must exist).
- `FileSystemPathDataFiles`: Path to directory where data node stores its Disk Data files. Default value is FilesystemPathDD, if set; otherwise, FilesystemPath is used if it is set; otherwise, value of DataDir is used.
- `FileSystemPathDD`: Path to directory where data node stores its Disk Data and undo files. Default value is FileSystemPath, if set; otherwise, value of DataDir is used.
- `FileSystemPathUndoFiles`: Path to directory where data node stores its undo files for Disk Data. Default value is FilesystemPathDD, if set; otherwise, FilesystemPath is used if it is set; otherwise, value of DataDir is used.
- `FragmentLogFileSize`: Size of each redo log file.
- `HeartbeatIntervalDbApi`: Time between API node-data node heartbeats. (API connection closed after 3 missed heartbeats).
- `HeartbeatIntervalDbDb`: Time between data node-to-data node heartbeats; data node considered dead after 3 missed heartbeats.
- `HeartbeatOrder`: Sets order in which data nodes check each others' heartbeats for determining whether given node is still active and connected to cluster. Must be zero for all data nodes or distinct nonzero values for all data nodes; see documentation for further guidance.
- `HostName`: Host name or IP address for this data node.
- `IndexMemory`: Number of bytes on each data node allocated for storing indexes; subject to available system RAM and size of DataMemory.
- `IndexStatAutoCreate`: Enable/disable automatic statistics collection when indexes are created.
- `IndexStatAutoUpdate`: Monitor indexes for changes and trigger automatic statistics updates.
- `IndexStatSaveScale`: Scaling factor used in determining size of stored index statistics.
- `IndexStatSaveSize`: Maximum size in bytes for saved statistics per index.
- `IndexStatTriggerPct`: Threshold percent change in DML operations for index statistics updates. Value is scaled down by IndexStatTriggerScale.

- [IndexStatTriggerScale](#): Scale down IndexStatTriggerPct by this amount, multiplied by base 2 logarithm of index size, for large index. Set to 0 to disable scaling.
- [IndexStatUpdateDelay](#): Minimum delay between automatic index statistics updates for given index. 0 means no delay.
- [InitFragmentLogFile](#)s: Initialize fragment logfiles (sparse/full).
- [InitialLogFileGroup](#): Describes log file group that is created during initial start. See documentation for format.
- [InitialNoOfOpenFiles](#): Initial number of files open per data node. (One thread is created per file).
- [InitialTablespace](#): Describes tablespace that is created during initial start. See documentation for format.
- [InsertRecoveryWork](#): Percentage of RecoveryWork used for inserted rows; has no effect unless partial local checkpoints are in use.
- [LateAlloc](#): Allocate memory after connection to management server has been established.
- [LcpScanProgressTimeout](#): Maximum time that local checkpoint fragment scan can be stalled before node is shut down to ensure systemwide LCP progress. Use 0 to disable.
- [LockExecuteThreadToCPU](#): Comma-delimited list of CPU IDs.
- [LockMaintThreadsToCPU](#): CPU ID indicating which CPU runs maintenance threads.
- [LockPagesInMainMemory](#): 0=disable locking, 1=lock after memory allocation, 2=lock before memory allocation.
- [LogLevelCheckpoint](#): Log level of local and global checkpoint information printed to stdout.
- [LogLevelCongestion](#): Level of congestion information printed to stdout.
- [LogLevelConnection](#): Level of node connect/disconnect information printed to stdout.
- [LogLevelError](#): Transporter, heartbeat errors printed to stdout.
- [LogLevelInfo](#): Heartbeat and log information printed to stdout.
- [LogLevelNodeRestart](#): Level of node restart and node failure information printed to stdout.
- [LogLevelShutdown](#): Level of node shutdown information printed to stdout.
- [LogLevelStartup](#): Level of node startup information printed to stdout.
- [LogLevelStatistic](#): Level of transaction, operation, and transporter information printed to stdout.
- [LongMessageBuffer](#): Number of bytes allocated on each data node for internal long messages.
- [MaxAllocate](#): No longer used; has no effect.
- [MaxBufferedEpochs](#): Allowed numbered of epochs that subscribing node can lag behind (unprocessed epochs). Exceeding causes lagging subscribers to be disconnected.
- [MaxBufferedEpochBytes](#): Total number of bytes allocated for buffering epochs.
- [MaxDiskWriteSpeed](#): Maximum number of bytes per second that can be written by LCP and backup when no restarts are ongoing.
- [MaxDiskWriteSpeedOtherNodeRestart](#): Maximum number of bytes per second that can be written by LCP and backup when another node is restarting.
- [MaxDiskWriteSpeedOwnRestart](#): Maximum number of bytes per second that can be written by LCP and backup when this node is restarting.

- **MaxFKBuildBatchSize**: Maximum scan batch size to use for building foreign keys. Increasing this value may speed up builds of foreign keys but impacts ongoing traffic as well.
- **MaxDMLOperationsPerTransaction**: Limit size of transaction; aborts transaction if it requires more than this many DML operations. Set to 0 to disable.
- **MaxLCPStartDelay**: Time in seconds that LCP polls for checkpoint mutex (to allow other data nodes to complete metadata synchronization), before putting itself in lock queue for parallel recovery of table data.
- **MaxNoOfAttributes**: Suggests total number of attributes stored in database (sum over all tables).
- **MaxNoOfConcurrentIndexOperations**: Total number of index operations that can execute simultaneously on one data node.
- **MaxNoOfConcurrentOperations**: Maximum number of operation records in transaction coordinator.
- **MaxNoOfConcurrentScans**: Maximum number of scans executing concurrently on data node.
- **MaxNoOfConcurrentSubOperations**: Maximum number of concurrent subscriber operations.
- **MaxNoOfConcurrentTransactions**: Maximum number of transactions executing concurrently on this data node, total number of transactions that can be executed concurrently is this value times number of data nodes in cluster.
- **MaxNoOfFiredTriggers**: Total number of triggers that can fire simultaneously on one data node.
- **MaxNoOfLocalOperations**: Maximum number of operation records defined on this data node.
- **MaxNoOfLocalScans**: Maximum number of fragment scans in parallel on this data node.
- **MaxNoOfOpenFiles**: Maximum number of files open per data node.(One thread is created per file).
- **MaxNoOfOrderedIndexes**: Total number of ordered indexes that can be defined in system.
- **MaxNoOfSavedMessages**: Maximum number of error messages to write in error log and maximum number of trace files to retain.
- **MaxNoOfSubscribers**: Maximum number of subscribers.
- **MaxNoOfSubscriptions**: Maximum number of subscriptions (default 0 = MaxNoOfTables).
- **MaxNoOfTables**: Suggests total number of NDB tables stored in database.
- **MaxNoOfTriggers**: Total number of triggers that can be defined in system.
- **MaxNoOfUniqueHashIndexes**: Total number of unique hash indexes that can be defined in system.
- **MaxParallelCopyInstances**: Number of parallel copies during node restarts. Default is 0, which uses number of LDMs on both nodes, to maximum of 16.
- **MaxParallelScansPerFragment**: Maximum number of parallel scans per fragment. Once this limit is reached, scans are serialized.
- **MaxReorgBuildBatchSize**: Maximum scan batch size to use for reorganization of table partitions. Increasing this value may speed up table partition reorganization but impacts ongoing traffic as well.
- **MaxStartFailRetries**: Maximum retries when data node fails on startup, requires StopOnError = 0. Setting to 0 causes start attempts to continue indefinitely.
- **MaxUIBuildBatchSize**: Maximum scan batch size to use for building unique keys. Increasing this value may speed up builds of unique keys but impacts ongoing traffic as well.

- `MemReportFrequency`: Frequency of memory reports in seconds; 0 = report only when exceeding percentage limits.
- `MinDiskWriteSpeed`: Minimum number of bytes per second that can be written by LCP and backup.
- `MinFreePct`: Percentage of memory resources to keep in reserve for restarts.
- `NodeGroup`: Node group to which data node belongs; used only during initial start of cluster.
- `NodeId`: Number uniquely identifying data node among all nodes in cluster.
- `NoOfFragmentLogFile`s: Number of 16 MB redo log files in each of 4 file sets belonging to data node.
- `NoOfReplicas`: Number of copies of all data in database.
- `Numa`: (Linux only; requires libnuma) Controls NUMA support. Setting to 0 permits system to determine use of interleaving by data node process; 1 means that it is determined by data node.
- `ODirect`: Use O\_DIRECT file reads and writes when possible.
- `ODirectSyncFlag`: O\_DIRECT writes are treated as synchronized writes; ignored when ODIRECT is not enabled, InitFragmentLogFile is set to SPARSE, or both.
- `RealtimeScheduler`: When true, data node threads are scheduled as real-time threads. Default is false.
- `RecoveryWork`: Percentage of storage overhead for LCP files: greater value means less work in normal operations, more work during recovery.
- `RedoBuffer`: Number of bytes on each data node allocated for writing redo logs.
- `RedoOverCommitCounter`: When RedoOverCommitLimit has been exceeded this many times, transactions are aborted, and operations are handled as specified by DefaultOperationRedoProblemAction.
- `RedoOverCommitLimit`: Each time that flushing current redo buffer takes longer than this many seconds, number of times that this has happened is compared to RedoOverCommitCounter.
- `ReservedSendBufferMemory`: This parameter is present in NDB code but is not enabled.
- `RestartOnErrorInsert`: Control type of restart caused by inserting error (when StopOnError is enabled).
- `SchedulerExecutionTimer`: Number of microseconds to execute in scheduler before sending.
- `SchedulerResponsiveness`: Set NDB scheduler response optimization 0-10; higher values provide better response time but lower throughput.
- `SchedulerSpinTimer`: Number of microseconds to execute in scheduler before sleeping.
- `ServerPort`: Port used to set up transporter for incoming connections from API nodes.
- `SharedGlobalMemory`: Total number of bytes on each data node allocated for any use.
- `StartFailRetryDelay`: Delay in seconds after start failure prior to retry; requires StopOnError = 0.
- `StartFailureTimeout`: Milliseconds to wait before terminating. (0=Wait forever).
- `StartNoNodeGroupTimeout`: Time to wait for nodes without nodegroup before trying to start (0=forever).
- `StartPartialTimeout`: Milliseconds to wait before trying to start without all nodes. (0=Wait forever).

- [StartPartitionedTimeout](#): Milliseconds to wait before trying to start partitioned. (0=Wait forever).
- [StartupStatusReportFrequency](#): Frequency of status reports during startup.
- [StopOnError](#): When set to 0, data node automatically restarts and recovers following node failures.
- [StringMemory](#): Default size of string memory (0 to 100 = % of maximum, 101+ = actual bytes).
- [TcpBind\\_INADDR\\_ANY](#): Bind IP\_ADDR\_ANY so that connections can be made from anywhere (for autogenerated connections).
- [TimeBetweenEpochs](#): Time between epochs (synchronization used for replication).
- [TimeBetweenEpochsTimeout](#): Timeout for time between epochs. Exceeding causes node shutdown.
- [TimeBetweenGlobalCheckpoints](#): Time between group commits of transactions to disk.
- [TimeBetweenGlobalCheckpointsTimeout](#): Minimum timeout for group commit of transactions to disk.
- [TimeBetweenInactiveTransactionAbortCheck](#): Time between checks for inactive transactions.
- [TimeBetweenLocalCheckpoints](#): Time between taking snapshots of database (expressed in base-2 logarithm of bytes).
- [TimeBetweenWatchDogCheck](#): Time between execution checks inside data node.
- [TimeBetweenWatchDogCheckInitial](#): Time between execution checks inside data node (early start phases when memory is allocated).
- [TotalSendBufferMemory](#): Total memory to use for all transporter send buffers..
- [TransactionBufferMemory](#): Dynamic buffer space (in bytes) for key and attribute data allocated for each data node.
- [TransactionDeadlockDetectionTimeout](#): Time transaction can spend executing within data node. This is time that transaction coordinator waits for each data node participating in transaction to execute request. If data node takes more than this amount of time, transaction is aborted.
- [TransactionInactiveTimeout](#): Milliseconds that application waits before executing another part of transaction. This is time transaction coordinator waits for application to execute or send another part (query, statement) of transaction. If application takes too much time, then transaction is aborted. Timeout = 0 means that application never times out.
- [TwoPassInitialNodeRestartCopy](#): Copy data in 2 passes during initial node restart, which enables multithreaded building of ordered indexes for such restarts.
- [UndoDataBuffer](#): Number of bytes on each data node allocated for writing data undo logs.
- [UndoIndexBuffer](#): Number of bytes on each data node allocated for writing index undo logs.
- [UseShm](#): Use shared memory connections between this data node and API node also running on this host.

The following parameters are specific to [ndbmttd](#):

- [MaxNoOfExecutionThreads](#): For ndbmttd only, specify maximum number of execution threads.
- [NoOfFragmentLogParts](#): Number of redo log file groups belonging to this data node.
- [ThreadConfig](#): Used for configuration of multithreaded data nodes (ndbmttd). Default is empty string; see documentation for syntax and other information.

### 21.3.2.2 NDB Cluster Management Node Configuration Parameters

The listing in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` section of a `config.ini` file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 21.3.3.5, “Defining an NDB Cluster Management Server”](#).

- `ArbitrationDelay`: When asked to arbitrate, arbitrator waits this long before voting (milliseconds).
- `ArbitrationRank`: If 0, then management node is not arbitrator. Kernel selects arbitrators in order 1, 2.
- `DataDir`: Data directory for this node.
- `ExecuteOnComputer`: String referencing earlier defined COMPUTER.
- `ExtraSendBufferMemory`: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- `HeartbeatIntervalMgmdMgmd`: Time between management-node-to-management-node heartbeats; connection between management nodes is considered lost after 3 missed heartbeats.
- `HeartbeatThreadPriority`: Set heartbeat thread policy and priority for management nodes; see manual for allowed values.
- `HostName`: Host name or IP address for this management node.
- `Id`: Number identifying management node. Now deprecated; use `NodeId` instead.
- `LogDestination`: Where to send log messages: console, system log, or specified log file.
- `NodeId`: Number uniquely identifying management node among all nodes in cluster.
- `PortNumber`: Port number to send commands to and fetch configuration from management server.
- `PortNumberStats`: Port number used to get statistical information from management server.
- `TotalSendBufferMemory`: Total memory to use for all transporter send buffers.
- `wan`: Use WAN TCP setting as default.

#### Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See [Section 21.3.3.5, “Defining an NDB Cluster Management Server”](#), for more information.

To add new management servers to a running NDB Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 21.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

### 21.3.2.3 NDB Cluster SQL Node and API Node Configuration Parameters

The listing in this section provides information about parameters used in the `[mysqld]` and `[api]` sections of a `config.ini` file for configuring NDB Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 21.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `ApiVerbose`: Enable NDB API debugging; for NDB development.
- `ArbitrationDelay`: When asked to arbitrate, arbitrator waits this many milliseconds before voting.

- [ArbitrationRank](#): If 0, then API node is not arbitrator. Kernel selects arbitrators in order 1, 2.
- [AutoReconnect](#): Specifies whether an API node should reconnect fully when disconnected from cluster.
- [BatchByteSize](#): Default batch size in bytes.
- [BatchSize](#): Default batch size in number of records.
- [ConnectBackoffMaxTime](#): Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, StartConnectBackoffMaxTime is used instead.
- [ConnectionMap](#): Specifies which data nodes to connect.
- [DefaultHashMapSize](#): Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840.
- [DefaultOperationRedoProblemAction](#): How operations are handled in event that RedoOverCommitCounter is exceeded.
- [ExecuteOnComputer](#): String referencing earlier defined COMPUTER.
- [ExtraSendBufferMemory](#): Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- [HeartbeatThreadPriority](#): Set heartbeat thread policy and priority for API nodes; see manual for allowed values.
- [HostName](#): Host name or IP address for this SQL or API node.
- [Id](#): Number identifying MySQL server or API node (Id). Now deprecated; use Nodeld instead.
- [MaxScanBatchSize](#): Maximum collective batch size for one scan.
- [NodeId](#): Number uniquely identifying SQL node or API node among all nodes in cluster.
- [StartConnectBackoffMaxTime](#): Same as ConnectBackoffMaxTime except that this parameter is used in its place if no data nodes are connected to this API node.
- [TotalSendBufferMemory](#): Total memory to use for all transporter send buffers.
- [wan](#): Use WAN TCP setting as default.

For a discussion of MySQL server options for NDB Cluster, see [MySQL Server Options for NDB Cluster](#). For information about MySQL server system variables relating to NDB Cluster, see [NDB Cluster System Variables](#).

### Note

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 21.3.2.4 Other NDB Cluster Configuration Parameters

The listings in this section provide information about parameters used in the `[computer]`, `[tcp]`, and `[shm]` sections of a `config.ini` file for configuring NDB Cluster. For detailed descriptions and additional information about individual parameters, see [Section 21.3.3.10, “NDB Cluster TCP/IP Connections”](#), or [Section 21.3.3.12, “NDB Cluster Shared Memory Connections”](#), as appropriate.

The following parameters apply to the `config.ini` file's `[computer]` section:

- `HostName`: Host name or IP address of this computer.
- `Id`: Unique identifier for this computer.

The following parameters apply to the `config.ini` file's `[tcp]` section:

- `Checksum`: If checksum is enabled, all signals between nodes are checked for errors.
- `Group`: Used for group proximity; smaller value is interpreted as being closer.
- `NodeId1`: ID of node (data node, API node, or management node) on one side of connection.
- `NodeId2`: ID of node (data node, API node, or management node) on one side of connection.
- `NodeIdServer`: Set server side of TCP connection.
- `OverloadLimit`: When more than this many unsent bytes are in send buffer, connection is considered overloaded.
- `PortNumber`: Port used for TCP transporter.
- `PreSendChecksum`: If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors.
- `Proxy`: .
- `ReceiveBufferMemory`: Bytes of buffer for signals received by this node.
- `SendBufferMemory`: Bytes of TCP buffer for signals sent from this node.
- `SendSignalId`: Sends ID in each signal. Used in trace files. Defaults to true in debug builds.
- `TCP_MAXSEG_SIZE`: Value used for TCP\_MAXSEG.
- `TCP_RCV_BUF_SIZE`: Value used for SO\_RCVBUF.
- `TCP SND_BUF_SIZE`: Value used for SO\_SNDBUF.
- `TcpBind_INADDR_ANY`: Bind InAddrAny instead of host name for server part of connection.

The following parameters apply to the `config.ini` file's `[shm]` section:

- `Checksum`: If checksum is enabled, all signals between nodes are checked for errors.
- `Group`: Used for group proximity; smaller value is interpreted as being closer.
- `NodeId1`: ID of node (data node, API node, or management node) on one side of connection.
- `NodeId2`: ID of node (data node, API node, or management node) on one side of connection.
- `NodeIdServer`: Set server side of SHM connection.
- `OverloadLimit`: When more than this many unsent bytes are in send buffer, connection is considered overloaded.
- `PortNumber`: Port used for SHM transporter.
- `PreSendChecksum`: If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors.

- [SendBufferMemory](#): Bytes in shared memory buffer for signals sent from this node.
- [SendSignalId](#): Sends ID in each signal. Used in trace files.
- [ShmKey](#): Shared memory key; when set to 1, this is calculated by NDB.
- [ShmSpinTime](#): When receiving, number of microseconds to spin before sleeping.
- [ShmSize](#): Size of shared memory segment.
- [Signum](#): Signal number to be used for signalling.

### 21.3.2.5 NDB Cluster mysqld Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in an NDB Cluster. For a table showing *all* command-line options, server and status variables available for use with `mysqld`, see [Section 5.1.3, “Server Option, System Variable, and Status Variable Reference”](#).

- [Com\\_show\\_ndb\\_status](#): Count of SHOW NDB STATUS statements.
- [Handler\\_discover](#): Number of times that tables have been discovered.
- [ndb-batch-size](#): Size (in bytes) to use for NDB transaction batches.
- [ndb-blob-read-batch-bytes](#): Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.
- [ndb-blob-write-batch-bytes](#): Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.
- [ndb-cluster-connection-pool](#): Number of connections to cluster used by MySQL.
- [ndb-cluster-connection-pool-nodeids](#): Comma-separated list of node IDs for connections to cluster used by MySQL; number of nodes in list must match value set for --ndb-cluster-connection-pool.
- [ndb-connectstring](#): Address of NDB management server distributing configuration information for this cluster.
- [ndb-default-column-format](#): Use this value (FIXED or DYNAMIC) by default for COLUMN\_FORMAT and ROW\_FORMAT options when creating or adding table columns.
- [ndb-deferred-constraints](#): Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.
- [ndb-distribution](#): Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).
- [ndb-log-apply-status](#): Cause MySQL server acting as replica to log mysql.ndb\_apply\_status updates received from its immediate source in its own binary log, using its own server ID. Effective only if server is started with --ndbcluster option.
- [ndb-log-empty-epochs](#): When enabled, causes epochs in which there were no changes to be written to ndb\_apply\_status and ndb\_binlog\_index tables, even when --log-slave-updates is enabled.
- [ndb-log-empty-update](#): When enabled, causes updates that produced no changes to be written to ndb\_apply\_status and ndb\_binlog\_index tables, even when --log-slave-updates is enabled.
- [ndb-log-exclusive-reads](#): Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.
- [ndb-log-fail-terminate](#): Terminate mysqld process if complete logging of all found row events is not possible.

- `ndb-log-orig`: Log originating server id and epoch in mysql.ndb\_binlog\_index table.
- `ndb-log-transaction-id`: Write NDB transaction IDs in binary log. Requires --log-bin-v1-events=OFF.
- `ndb-log-update-as-write`: Toggles logging of updates on source between updates (OFF) and writes (ON).
- `ndb-mgmd-host`: Set host (and port, if desired) for connecting to management server.
- `ndb-nodeid`: NDB Cluster node ID for this MySQL server.
- `ndb-optimized-node-selection`: Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable.
- `ndb-transid-mysql-connection-map`: Enable or disable `ndb_transid_mysql_connection_map` plugin; that is, enable or disable INFORMATION\_SCHEMA table having that name.
- `ndb-wait-connected`: Time (in seconds) for MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections.
- `ndb-wait-setup`: Time (in seconds) for MySQL server to wait for NDB engine setup to complete.
- `ndb-allow-copying-alter-table`: Set to OFF to keep ALTER TABLE from using copying operations on NDB tables.
- `Ndb_api_adaptive_send_deferred_count`: Number of adaptive send calls not actually sent by this MySQL Server (SQL node).
- `Ndb_api_adaptive_send_deferred_count_session`: Number of adaptive send calls not actually sent in this client session.
- `Ndb_api_adaptive_send_deferred_count_slave`: Number of adaptive send calls not actually sent by this replica.
- `Ndb_api_adaptive_send_forced_count`: Number of adaptive sends with forced-send set sent by this MySQL Server (SQL node).
- `Ndb_api_adaptive_send_forced_count_session`: Number of adaptive sends with forced-send set in this client session.
- `Ndb_api_adaptive_send_forced_count_slave`: Number of adaptive sends with forced-send set sent by this replica.
- `Ndb_api_adaptive_send_unforced_count`: Number of adaptive sends without forced-send sent by this MySQL Server (SQL node).
- `Ndb_api_adaptive_send_unforced_count_session`: Number of adaptive sends without forced-send in this client session.
- `Ndb_api_adaptive_send_unforced_count_slave`: Number of adaptive sends without forced-send sent by this replica.
- `Ndb_api_bytes_received_count`: Quantity of data (in bytes) received from data nodes by this MySQL Server (SQL node).
- `Ndb_api_bytes_received_count_session`: Quantity of data (in bytes) received from data nodes in this client session.
- `Ndb_api_bytes_received_count_slave`: Quantity of data (in bytes) received from data nodes by this replica.
- `Ndb_api_bytes_sent_count`: Quantity of data (in bytes) sent to data nodes by this MySQL Server (SQL node).

- `Ndb_api_bytes_sent_count_session`: Quantity of data (in bytes) sent to data nodes in this client session.
- `Ndb_api_bytes_sent_count_slave`: Quantity of data (in bytes) sent to data nodes by this replica.
- `Ndb_api_event_bytes_count`: Number of bytes of events received by this MySQL Server (SQL node).
- `Ndb_api_event_bytes_count_injector`: Number of bytes of event data received by NDB binary log injector thread.
- `Ndb_api_event_data_count`: Number of row change events received by this MySQL Server (SQL node).
- `Ndb_api_event_data_count_injector`: Number of row change events received by NDB binary log injector thread.
- `Ndb_api_event_nodata_count`: Number of events received, other than row change events, by this MySQL Server (SQL node).
- `Ndb_api_event_nodata_count_injector`: Number of events received, other than row change events, by NDB binary log injector thread.
- `Ndb_api_pk_op_count`: Number of operations based on or using primary keys by this MySQL Server (SQL node).
- `Ndb_api_pk_op_count_session`: Number of operations based on or using primary keys in this client session.
- `Ndb_api_pk_op_count_slave`: Number of operations based on or using primary keys by this replica.
- `Ndb_api_pruned_scan_count`: Number of scans that have been pruned to one partition by this MySQL Server (SQL node).
- `Ndb_api_pruned_scan_count_session`: Number of scans that have been pruned to one partition in this client session.
- `Ndb_api_pruned_scan_count_slave`: Number of scans that have been pruned to one partition by this replica.
- `Ndb_api_range_scan_count`: Number of range scans that have been started by this MySQL Server (SQL node).
- `Ndb_api_range_scan_count_session`: Number of range scans that have been started in this client session.
- `Ndb_api_range_scan_count_slave`: Number of range scans that have been started by this replica.
- `Ndb_api_read_row_count`: Total number of rows that have been read by this MySQL Server (SQL node).
- `Ndb_api_read_row_count_session`: Total number of rows that have been read in this client session.
- `Ndb_api_read_row_count_slave`: Total number of rows that have been read by this replica.
- `Ndb_api_scan_batch_count`: Number of batches of rows received by this MySQL Server (SQL node).
- `Ndb_api_scan_batch_count_session`: Number of batches of rows received in this client session.

- `Ndb_api_scan_batch_count_slave`: Number of batches of rows received by this replica.
- `Ndb_api_table_scan_count`: Number of table scans that have been started, including scans of internal tables, by this MySQL Server (SQL node).
- `Ndb_api_table_scan_count_session`: Number of table scans that have been started, including scans of internal tables, in this client session.
- `Ndb_api_table_scan_count_slave`: Number of table scans that have been started, including scans of internal tables, by this replica.
- `Ndb_api_trans_abort_count`: Number of transactions aborted by this MySQL Server (SQL node).
- `Ndb_api_trans_abort_count_session`: Number of transactions aborted in this client session.
- `Ndb_api_trans_abort_count_slave`: Number of transactions aborted by this replica.
- `Ndb_api_trans_close_count`: Number of transactions aborted (may be greater than sum of TransCommitCount and TransAbortCount) by this MySQL Server (SQL node).
- `Ndb_api_trans_close_count_session`: Number of transactions aborted (may be greater than sum of TransCommitCount and TransAbortCount) in this client session.
- `Ndb_api_trans_close_count_slave`: Number of transactions aborted (may be greater than sum of TransCommitCount and TransAbortCount) by this replica.
- `Ndb_api_trans_commit_count`: Number of transactions committed by this MySQL Server (SQL node).
- `Ndb_api_trans_commit_count_session`: Number of transactions committed in this client session.
- `Ndb_api_trans_commit_count_slave`: Number of transactions committed by this replica.
- `Ndb_api_trans_local_read_row_count`: Total number of rows that have been read by this MySQL Server (SQL node).
- `Ndb_api_trans_local_read_row_count_session`: Total number of rows that have been read in this client session.
- `Ndb_api_trans_local_read_row_count_slave`: Total number of rows that have been read by this replica.
- `Ndb_api_trans_start_count`: Number of transactions started by this MySQL Server (SQL node).
- `Ndb_api_trans_start_count_session`: Number of transactions started in this client session.
- `Ndb_api_trans_start_count_slave`: Number of transactions started by this replica.
- `Ndb_api_uk_op_count`: Number of operations based on or using unique keys by this MySQL Server (SQL node).
- `Ndb_api_uk_op_count_session`: Number of operations based on or using unique keys in this client session.
- `Ndb_api_uk_op_count_slave`: Number of operations based on or using unique keys by this replica.
- `Ndb_api_wait_exec_complete_count`: Number of times thread has been blocked while waiting for operation execution to complete by this MySQL Server (SQL node).
- `Ndb_api_wait_exec_complete_count_session`: Number of times thread has been blocked while waiting for operation execution to complete in this client session.

- [`Ndb\_api\_wait\_exec\_complete\_count\_slave`](#): Number of times thread has been blocked while waiting for operation execution to complete by this replica.
- [`Ndb\_api\_wait\_meta\_request\_count`](#): Number of times thread has been blocked waiting for metadata-based signal by this MySQL Server (SQL node).
- [`Ndb\_api\_wait\_meta\_request\_count\_session`](#): Number of times thread has been blocked waiting for metadata-based signal in this client session.
- [`Ndb\_api\_wait\_meta\_request\_count\_slave`](#): Number of times thread has been blocked waiting for metadata-based signal by this replica.
- [`Ndb\_api\_wait\_nanos\_count`](#): Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this MySQL Server (SQL node).
- [`Ndb\_api\_wait\_nanos\_count\_session`](#): Total time (in nanoseconds) spent waiting for some type of signal from data nodes in this client session.
- [`Ndb\_api\_wait\_nanos\_count\_slave`](#): Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this replica.
- [`Ndb\_api\_wait\_scan\_result\_count`](#): Number of times thread has been blocked while waiting for scan-based signal by this MySQL Server (SQL node).
- [`Ndb\_api\_wait\_scan\_result\_count\_session`](#): Number of times thread has been blocked while waiting for scan-based signal in this client session.
- [`Ndb\_api\_wait\_scan\_result\_count\_slave`](#): Number of times thread has been blocked while waiting for scan-based signal by this replica.
- [`ndb\_autoincrement\_prefetch\_sz`](#): NDB auto-increment prefetch size.
- [`ndb\_cache\_check\_time`](#): Number of milliseconds between checks of cluster SQL nodes made by MySQL query cache.
- [`ndb\_clear\_apply\_status`](#): Causes RESET SLAVE/RESET REPLICA to clear all rows from `ndb_apply_status` table; ON by default.
- [`Ndb\_cluster\_node\_id`](#): Node ID of this server when acting as NDB Cluster SQL node.
- [`Ndb\_config\_from\_host`](#): NDB Cluster management server host name or IP address.
- [`Ndb\_config\_from\_port`](#): Port for connecting to NDB Cluster management server.
- [`Ndb\_conflict\_fn\_epoch`](#): Number of rows that have been found in conflict by `NDB$EPOCH()` conflict detection function.
- [`Ndb\_conflict\_fn\_epoch2`](#): Number of rows that have been found in conflict by `NDB$EPOCH2()` conflict detection function.
- [`Ndb\_conflict\_fn\_epoch2\_trans`](#): Number of rows that have been found in conflict by `NDB$EPOCH2_TRANS()` conflict detection function.
- [`Ndb\_conflict\_fn\_epoch\_trans`](#): Number of rows that have been found in conflict by `NDB$EPOCH_TRANS()` conflict detection function.
- [`Ndb\_conflict\_fn\_max`](#): Number of times that conflict resolution based on "greater timestamp wins" has been applied when server is part of an NDB Cluster involved in cluster replication.
- [`Ndb\_conflict\_fn\_old`](#): Number of times that "same timestamp wins" conflict resolution has been applied when this server is part of an NDB Cluster involved in cluster replication.
- [`Ndb\_conflict\_last\_conflict\_epoch`](#): Most recent NDB epoch on this replica in which some conflict was detected.

- `Ndb_conflict_last_stable_epoch`: Number of rows found to be in conflict by transactional conflict function.
- `Ndb_conflict_reflected_op_discard_count`: Number of reflected operations that were not applied due error during execution.
- `Ndb_conflict_reflected_op_prepare_count`: Number of reflected operations received that have been prepared for execution.
- `Ndb_conflict_refresh_op_count`: Number of refresh operations that have been prepared.
- `Ndb_conflict_trans_conflict_commit_count`: Number of epoch transactions committed after requiring transactional conflict handling.
- `Ndb_conflict_trans_detect_iter_count`: Number of internal iterations required to commit epoch transaction. Should be (slightly) greater than or equal to `Ndb_conflict_trans_conflict_commit_count`.
- `Ndb_conflict_trans_reject_count`: Number of transactions rejected after being found in conflict by transactional conflict function.
- `Ndb_conflict_trans_row_conflict_count`: Number of rows found in conflict by transactional conflict function. Includes any rows included in or dependent on conflicting transactions.
- `Ndb_conflict_trans_row_reject_count`: Total number of rows realigned after being found in conflict by transactional conflict function. Includes `Ndb_conflict_trans_row_conflict_count` and any rows included in or dependent on conflicting transactions.
- `ndb_data_node_neighbour`: Specifies cluster data node "closest" to this MySQL Server, for transaction hinting and fully replicated tables.
- `ndb_default_column_format`: Sets default row format and column format (FIXED or DYNAMIC) used for new NDB tables.
- `ndb_deferred_constraints`: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.
- `ndb_distribution`: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).
- `Ndb_epoch_delete_delete_count`: Number of delete-delete conflicts detected (delete operation is applied, but row does not exist).
- `ndb_eventbuffer_free_percent`: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by `ndb_eventbuffer_max_alloc`.
- `ndb_eventbuffer_max_alloc`: Maximum memory that can be allocated for buffering events by NDB API. Defaults to 0 (no limit).
- `Ndb_execute_count`: Number of round trips to NDB kernel made by operations.
- `ndb_extra_logging`: Controls logging of NDB Cluster schema, connection, and data distribution events in MySQL error log.
- `ndb_force_send`: Forces sending of buffers to NDB immediately, without waiting for other threads.
- `ndb_fully_replicated`: Whether new NDB tables are fully replicated.
- `ndb_index_stat_enable`: Use NDB index statistics in query optimization.
- `ndb_index_stat_option`: Comma-separated list of tunable options for NDB index statistics; list should contain no spaces.
- `ndb_join_pushdown`: Enables pushing down of joins to data nodes.

- [Ndb\\_last\\_commit\\_epoch\\_server](#): Epoch most recently committed by NDB.
- [Ndb\\_last\\_commit\\_epoch\\_session](#): Epoch most recently committed by this NDB client.
- [ndb\\_log\\_apply\\_status](#): Whether or not MySQL server acting as replica logs mysql.ndb\_apply\_status updates received from its immediate source in its own binary log, using its own server ID.
- [ndb\\_log\\_bin](#): Write updates to NDB tables in binary log. Effective only if binary logging is enabled with --log-bin.
- [ndb\\_log\\_binlog\\_index](#): Insert mapping between epochs and binary log positions into ndb\_binlog\_index table. Defaults to ON. Effective only if binary logging is enabled.
- [ndb\\_log\\_empty\\_epochs](#): When enabled, epochs in which there were no changes are written to ndb\_apply\_status and ndb\_binlog\_index tables, even when log\_slave\_updates is enabled.
- [ndb\\_log\\_empty\\_update](#): When enabled, updates which produce no changes are written to ndb\_apply\_status and ndb\_binlog\_index tables, even when log\_slave\_updates is enabled.
- [ndb\\_log\\_exclusive\\_reads](#): Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.
- [ndb\\_log\\_orig](#): Whether id and epoch of originating server are recorded in mysql.ndb\_binlog\_index table. Set using --ndb-log-orig option when starting mysqld.
- [ndb\\_log\\_transaction\\_id](#): Whether NDB transaction IDs are written into binary log (Read-only).
- [ndb\\_log-update-minimal](#): Log updates in minimal format.
- [ndb\\_log-updated-only](#): Log complete rows (ON) or updates only (OFF).
- [Ndb\\_number\\_of\\_data\\_nodes](#): Number of data nodes in this NDB cluster; set only if server participates in cluster.
- [ndb\\_optimization-delay](#): Number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables.
- [ndb\\_optimized\\_node\\_selection](#): Determines how SQL node chooses cluster data node to use as transaction coordinator.
- [Ndb\\_pruned\\_scan\\_count](#): Number of scans executed by NDB since cluster was last started where partition pruning could be used.
- [Ndb\\_pushed\\_queries\\_defined](#): Number of joins that API nodes have attempted to push down to data nodes.
- [Ndb\\_pushed\\_queries\\_dropped](#): Number of joins that API nodes have tried to push down, but failed.
- [Ndb\\_pushed\\_queries\\_executed](#): Number of joins successfully pushed down and executed on data nodes.
- [Ndb\\_pushed\\_reads](#): Number of reads executed on data nodes by pushed-down joins.
- [ndb\\_read\\_backup](#): Enable read from any replica for all NDB tables; use NDB\_TABLE=READ\_BACKUP={0|1} with CREATE TABLE or ALTER TABLE to enable or disable for individual NDB tables.
- [ndb\\_recv\\_thread\\_activation\\_threshold](#): Activation threshold when receive thread takes over polling of cluster connection (measured in concurrently active threads).
- [ndb\\_recv\\_thread\\_cpu\\_mask](#): CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.

- `ndb_report_thresh_binlog_epoch_slip`: NDB 7.5.4 and later: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates BUFFERED\_EPOCHS\_OVER\_THRESHOLD event buffer status message; prior to NDB 7.5.4: Threshold for number of epochs to lag behind before reporting binary log status.
- `ndb_report_thresh_binlog_mem_usage`: Threshold for percentage of free memory remaining before reporting binary log status.
- `ndb_row_checksum`: When enabled, set row checksums; enabled by default.
- `Ndb_scan_count`: Total number of scans executed by NDB since cluster was last started.
- `ndb_show_foreign_key_mock_tables`: Show mock tables used to support foreign\_key\_checks=0.
- `ndb_slave_conflict_role`: Role for replica to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when replication SQL thread is stopped. See documentation for further information.
- `Ndb_slave_max_replicated_epoch`: Most recently committed NDB epoch on this replica. When this value is greater than or equal to `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.
- `Ndb_system_name`: Configured cluster system name; empty if server not connected to NDB.
- `ndb_table_no_logging`: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). Setting in effect when table is created with or altered to use NDBCLUSTER persists for table's lifetime.
- `ndb_table_temporary`: NDB tables are not persistent on disk: no schema files are created and tables are not logged.
- `ndb_use_copying_alter_table`: Use copying ALTER TABLE operations in NDB Cluster.
- `ndb_use_exact_count`: Use exact row count when planning queries.
- `ndb_use_transactions`: Forces NDB to use a count of records during SELECT COUNT(\*) query planning to speed up this type of query.
- `ndb_version`: Shows build and NDB engine version as an integer.
- `ndb_version_string`: Shows build information including NDB engine version in `ndb-x.y.z` format.
- `ndbcluster`: Enable NDB Cluster (if this version of MySQL supports it). Disabled by `--skip-ndbcluster`.
- `ndbinfo_database`: Name used for NDB information database; read only.
- `ndbinfo_max_bytes`: Used for debugging only.
- `ndbinfo_max_rows`: Used for debugging only.
- `ndbinfo_offline`: Put ndbinfo database into offline mode, in which no rows are returned from tables or views.
- `ndbinfo_show_hidden`: Whether to show ndbinfo internal base tables in mysql client; default is OFF.
- `ndbinfo_table_prefix`: Prefix to use for naming ndbinfo internal base tables; read only.
- `ndbinfo_version`: ndbinfo engine version; read only.
- `server_id_bits`: Number of least significant bits in `server_id` actually used for identifying server, permitting NDB API applications to store application data in most significant bits. `server_id` must be less than 2 to power of this value.

- `skip_ndbcluster`: Disable NDB Cluster storage engine.
- `slave_allow_batching`: Turns update batching on and off for replica.
- `transaction_allow_batching`: Allows batching of statements within one transaction. Disable AUTOCOMMIT to use.

### 21.3.3 NDB Cluster Configuration Files

Configuring NDB Cluster requires working with two files:

- `my.cnf`: Specifies options for all NDB Cluster executables. This file, with which you should be familiar from previous work with MySQL, must be accessible by each executable running in the cluster.
- `config.ini`: This file, sometimes known as the *global configuration file*, is read only by the NDB Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see [Sections of the config.ini File](#).

**Caching of configuration data.** NDB uses *stateful configuration*. Rather than reading the global configuration file every time the management server is restarted, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

- **The management server is started using the --initial option.** When `--initial` is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.
- **The management server is started using the --reload option.** The `--reload` option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.
- **The management server is started using --config-cache=FALSE.** This disables `--config-cache` (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the `config.ini` file instead.
- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

**Configuration cache files.** The management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build NDB Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at runtime by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_node_id_config.bin.seq_id`, where `node_id` is the management server's node ID in the cluster, and `seq_id` is a cache identifier. Cache files are numbered sequentially using `seq_id`, in the order in which they are created. The management server uses the latest cache file as determined by the `seq_id`.

#### Note

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher `seq_id`. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--config-cache`, `--initial`, and `--reload` options for the NDB Cluster management server, see [Section 21.4.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#).

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we try to let NDB Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#).

### 21.3.3.1 NDB Cluster Configuration: Basic Example

To support NDB Cluster, you must to update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

#### Note

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```
my.cnf
example additions to my.cnf for NDB Cluster
(valid in MySQL 5.7)

enable ndbcluster storage engine, and provide connection string for
management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

provide location of cluster configuration file
IMPORTANT: When starting the management server with this option in the
configuration file, the use of --initial or --reload on the command line when
invoking ndb_mgmd is also required.
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connection strings, see [Section 21.3.3.3, “NDB Cluster Connection Strings”](#).)

```
my.cnf
example additions to my.cnf for NDB Cluster
(works on all versions)

enable ndbcluster storage engine, and provide connection string for management
server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

#### Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements fail with an error. *This is by design.*

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional NDB variables that can be set in the `my.cnf` file, see [NDB Cluster System Variables](#).

The NDB Cluster global configuration file is by convention named `config.ini` (but this is not required). If needed, it is read by `ndb_mgmd` at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using `--config-file=path_name` with `ndb_mgmd` on the command line. This option has no default value, and is ignored if `ndb_mgmd` uses the configuration cache.

The global configuration file for NDB Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (`:`) as well as the equal sign (`=`); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` line to specify the data memory size.

If used, the `[ndbd default]` section must precede any `[ndbd]` sections in the configuration file. This is also true for `default` sections of any other type.

#### Note

In some older releases of NDB Cluster, there was no default value for `NoOfReplicas`, which always had to be specified explicitly in the `[ndbd default]` section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
file "config.ini" - 2 data nodes and 2 SQL nodes
This file is placed in the startup directory of ndb_mgmd (the
management server)
The first MySQL Server can be started from any host. The second
can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com
```

```
[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

**Note**

The preceding example is intended as a minimal starting configuration for purposes of familiarization with NDB Cluster , and is almost certain not to be sufficient for production settings. See [Section 21.3.3.2, “Recommended Starting Configuration for NDB Cluster”](#), which provides a more complete example starting configuration.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[ndbd]` sections defining these nodes.

**Note**

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

**Sections of the config.ini File**

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[computer]`: Defines cluster hosts. This is not required to configure a viable NDB Cluster, but be may used as a convenience when setting up a large cluster. See [Section 21.3.3.4, “Defining Computers in an NDB Cluster”](#), for more information.
- `[ndbd]`: Defines a cluster data node (`ndbd` process). See [Section 21.3.3.6, “Defining NDB Cluster Data Nodes”](#), for details.
- `[mysqld]`: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see [Section 21.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).
- `[mgm]` or `[ndb_mgmd]`: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see [Section 21.3.3.5, “Defining an NDB Cluster Management Server”](#).
- `[tcp]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default transport protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up an NDB Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See [Section 21.3.3.10, “NDB Cluster TCP/IP Connections”](#), for information about available TCP/IP configuration parameters and how to use them. (You may also find [Section 21.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”](#) to be of interest in some cases.)
- `[shm]`: Defines shared-memory connections between nodes. In MySQL 5.7, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see [Section 21.3.3.12, “NDB Cluster Shared Memory Connections”](#).
- `[sci]`: Defines Scalable Coherent Interface connections between cluster data nodes. Not supported in NDB 7.5 or 7.6.

You can define `default` values for each section. If used, a `default` section should come before any other sections of that type. For example, an `[ndbd default]` section should appear in the configuration file before any `[ndbd]` sections.

NDB Cluster parameter names are case-insensitive, unless specified in MySQL Server `my.cnf` or `my.ini` files.

### 21.3.3.2 Recommended Starting Configuration for NDB Cluster

Achieving the best performance from an NDB Cluster depends on a number of factors including the following:

- NDB Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each NDB Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the NDB Cluster's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.

**Starting config.ini file.** The following `config.ini` file is a recommended starting point for configuring a cluster running NDB Cluster 7.5:

```
TCP PARAMETERS

[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

Increasing the sizes of these 2 buffers beyond the default values
helps prevent bottlenecks due to slow disk I/O.

MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

It is possible to use a different data directory for each management
server, but for ease of administration it is preferable to be
consistent.

[ndb_mgmd]
HostName=management-server-A-hostname
NodeId=management-server-A-nodeid

[ndb_mgmd]
HostName=management-server-B-hostname
NodeId=management-server-B-nodeid

Using 2 management servers helps guarantee that there is always an
arbitrator in the event of network partitioning, and so is
recommended for high availability. Each management server must be
identified by a HostName. You may for the sake of convenience specify
a NodeId for any management server, although one is allocated
for it automatically; if you do so, it must be in the range 1-255
inclusive and must be unique among all IDs specified for cluster
nodes.

DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas=2

Using two fragment replicas is recommended to guarantee availability of data;
using only one fragment replica does not provide any redundancy, which means
```

```

that the failure of a single data node causes the entire cluster to
shut down. We do not recommend using more than two fragment replicas, since
two are sufficient to provide high availability, and we do not currently test
with greater values for this parameter.

LockPagesInMainMemory=1

On Linux and Solaris systems, setting this parameter locks data node
processes into memory. Doing so prevents them from swapping to disk,
which can severely degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

The values provided for DataMemory and IndexMemory assume 4 GB RAM
per data node. However, for best results, you should first calculate
the memory that would be used based on the data you actually plan to
store (you may find the ndb_size.pl utility helpful in estimating
this), then allow an extra 20% over the calculated values. Naturally,
you should ensure that each data node host has at least as much
physical memory as the sum of these two values.
NOTE: IndexMemory is deprecated in NDB 7.6 and later.

ODirect=1

Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
writes for local checkpoints and redo logs; this can reduce load on
CPUs. We recommend doing so when using NDB Cluster on systems running
Linux kernel 2.6 or later.

NoOfFragmentLogFile=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1
Setting these parameters allows you to take advantage of real-time scheduling
of NDB threads to achieve increased throughput when using ndbd. They
are not needed when using ndbmtd; in particular, you should not set
RealTimeScheduler for ndbmtd data nodes.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
RedoBuffer=32M

CompressedLCP=1
CompressedBackup=1
Enabling CompressedLCP and CompressedBackup causes, respectively, local
checkpoint files and backup files to be compressed, which can result in a space
savings of up to 50% over noncompressed LCPs and backups.

MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
NodeId=data-node-A-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
threads to specific CPUs

[ndbd]
HostName=data-node-B-hostname
NodeId=data-node-B-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

```

```

You must have an [ndbd] section for every data node in the cluster;
each of these sections must include a HostName. Each section may
optionally include a NodeId for convenience, but in most cases, it is
sufficient to allow the cluster to allocate node IDs dynamically. If
you do specify the node ID for a data node, it must be in the range 1
to 48 inclusive and must be unique among all IDs specified for
cluster nodes.

SQL NODE / API NODE PARAMETERS

[mysqld]
HostName=sql-node-A-hostname
NodeId=mysql-node-A-nodeid

[mysqld]

[mysqld]

Each API or SQL node that connects to the cluster requires a [mysqld]
or [api] section of its own. Each such section defines a connection
"slot"; you should have at least as many of these sections in the
config.ini file as the total number of API nodes and SQL nodes that
you wish to have connected to the cluster at any given time. There is
no performance or other penalty for having extra slots available in
case you find later that you want or need more API or SQL nodes to
connect to the cluster at the same time.
If no HostName is specified for a given [mysqld] or [api] section,
then any API or SQL node may use that slot to connect to the
cluster. You may wish to use an explicit HostName for one connection slot
to guarantee that an API or SQL node from that host can always
connect to the cluster. If you wish to prevent API or SQL nodes from
connecting from other than a desired host or hosts, then use a
HostName for every [mysqld] or [api] section in the config.ini file.
You can if you wish define a node ID (NodeId parameter) for any API or
SQL node, but this is not necessary; if you do so, it must be in the
range 1 to 255 inclusive and must be unique among all IDs specified
for cluster nodes.

```

**Recommended my.cnf options for SQL nodes.** MySQL Servers acting as NDB Cluster SQL nodes must always be started with the `--ndbcluster` and `--ndb-connectstring` options, either on the command line or in `my.cnf`. In addition, set the following options for all `mysqld` processes in the cluster, unless your setup requires otherwise:

- `--ndb-use-exact-count=0`
- `--ndb-index-stat-enable=0`
- `--ndb-force-send=1`
- `--optimizer-switch=engine_condition_pushdown=on`

### 21.3.3.3 NDB Cluster Connection Strings

With the exception of the NDB Cluster management server (`ndb_mgmd`), each node that is part of an NDB Cluster requires a *connection string* that points to the management server's location. This connection string is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connection string is as follows:

```

[nodeid=node_id,]host-definition[, host-definition[, ...]]

host-definition:
 host_name[:port_number]

```

`node_id` is an integer greater than or equal to 1 which identifies a node in `config.ini`. `host_name` is a string representing a valid Internet host name or IP address. `port_number` is an integer referring to a TCP/IP port number.

```
example 1 (long): "nodeid=2,myhost1:1100,myhost2:1100,198.51.100.3:1200"
example 2 (short): "myhost1"
```

`localhost:1186` is used as the default connection string value if none is provided. If `port_num` is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see <http://www.iana.org/assignments/port-numbers> for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. An NDB Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

It is also possible to specify in a connection string one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```
[nodeid=node_id,]
[bind-address=host-definition,]
host-definition[; bind-address=host-definition]
host-definition[; bind-address=host-definition]
[, ...]]
```

`host-definition:`

```
host_name[:port_number]
```

If a single bind address is used in the connection string *prior* to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use `198.51.100.242` regardless of the management server to which it connects:

```
bind-address=198.51.100.242, poseidon:1186, perch:1186
```

If a bind address is specified *following* a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=198.51.100.242
```

In this case, the node uses `localhost` to connect to the management server running on the host named `poseidon` and `198.51.100.242` to connect to the management server running on the host named `perch`.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, `localhost` is used for connecting to the management server running on host `poseidon`; since `198.51.100.242` is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts `perch` and `orca`:

```
bind-address=198.51.100.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.
- For backward compatibility, two other options are available, using the same syntax:
  1. Set the `NDB_CONNECTSTRING` environment variable to contain the connection string.

2. Write the connection string for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the `my.cnf` file for each executable.

#### 21.3.3.4 Defining Computers in an NDB Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

|                    |                |
|--------------------|----------------|
| Version (or later) | NDB 7.5.0      |
| Type or units      | string         |
| Default            | [...]          |
| Range              | ...            |
| Restart Type       | IS (NDB 7.5.0) |

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

#### Important

The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- `HostName`

|                    |                    |
|--------------------|--------------------|
| Version (or later) | NDB 7.5.0          |
| Type or units      | name or IP address |
| Default            | [...]              |
| Range              | ...                |
| Restart Type       | N (NDB 7.5.0)      |

This is the computer's hostname or IP address.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 21.7 NDB Cluster restart types**

| Symbol | Restart Type | Description                                                                                                                                  |
|--------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| N      | Node         | The parameter can be updated using a rolling restart (see <a href="#">Section 21.5.5, "Performing a Rolling Restart of an NDB Cluster"</a> ) |
| S      | System       | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter                                         |
| I      | Initial      | Data nodes must be restarted using the <code>--initial</code> option                                                                         |

#### 21.3.3.5 Defining an NDB Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an

[`ndb_mgmd default`] section. [`mgm`] and [`mgm default`] are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

#### Note

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` is assumed for both.

- `Id`

|                    |                |
|--------------------|----------------|
| Version (or later) | NDB 7.5.0      |
| Type or units      | unsigned       |
| Default            | [...]          |
| Range              | 1 - 255        |
| Restart Type       | IS (NDB 7.5.0) |

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

#### Note

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of NDB Cluster.

- `NodeId`

|                    |                |
|--------------------|----------------|
| Version (or later) | NDB 7.5.0      |
| Type or units      | unsigned       |
| Default            | [...]          |
| Range              | 1 - 255        |
| Restart Type       | IS (NDB 7.5.0) |

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

#### Note

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes. Although the older `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future NDB Cluster release.

- `ExecuteOnComputer`

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | name          |
| Default             | [...]         |
| Range               | ...           |
| Deprecated          | NDB 7.5.0     |
| <b>Restart Type</b> | S (NDB 7.5.0) |

This refers to the [Id](#) set for one of the computers defined in a [\[computer\]](#) section of the [config.ini](#) file.

### Important

This parameter is deprecated as of NDB 7.5.0, and is subject to removal in a future release. Use the [HostName](#) parameter instead.

- [PortNumber](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | unsigned      |
| Default             | 1186          |
| Range               | 0 - 64K       |
| <b>Restart Type</b> | S (NDB 7.5.0) |

This is the port number on which the management server listens for configuration requests and management commands.

- [HostName](#)

|                     |                    |
|---------------------|--------------------|
| Version (or later)  | NDB 7.5.0          |
| Type or units       | name or IP address |
| Default             | [...]              |
| Range               | ...                |
| <b>Restart Type</b> | N (NDB 7.5.0)      |

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than [localhost](#), either this parameter or [ExecuteOnComputer](#) is required.

- [LocationDomainId](#)

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.6.4 |
| Type or units      | integer   |
| Default            | 0         |
| Range              | 0 - 16    |
| Added              | NDB 7.6.4 |

|              |               |
|--------------|---------------|
| Restart Type | S (NDB 7.5.0) |
|--------------|---------------|

Assigns a management node to a specific [availability domain](#) (also known as an availability zone) within a cloud. By informing [NDB](#) which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use [NDB](#) transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

[LocationDomainId](#) takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- [LogDestination](#)

|                    |                                                                    |
|--------------------|--------------------------------------------------------------------|
| Version (or later) | NDB 7.5.0                                                          |
| Type or units      | {CONSOLE SYSLOG FILE}                                              |
| Default            | FILE: filename=ndb_nodeid_cluster.log, maxsize=1000000, maxfiles=6 |
| Range              | ...                                                                |

|              |               |
|--------------|---------------|
| Restart Type | N (NDB 7.5.0) |
|--------------|---------------|

This parameter specifies where to send cluster logging information. There are three options in this regard—[CONSOLE](#), [SYSLOG](#), and [FILE](#)—with [FILE](#) being the default:

- [CONSOLE](#) outputs the log to `stdout`:

```
CONSOLE
```

- [SYSLOG](#) sends the log to a [syslog](#) facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

#### Note

Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- [FILE](#) pipes the cluster log output to a regular file on the same machine. The following values can be specified:

- `filename`: The name of the log file.

The default log file name used in such cases is `ndb_nodeid_cluster.log`.

- `maxsize`: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.
- `maxfiles`: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default value for the [FILE](#) parameter is

`FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6`, where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- [ArbitrationRank](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | 0-2           |
| Default            | 1             |
| Range              | 0 - 2         |
| Restart Type       | N (NDB 7.5.0) |

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. [ArbitrationRank](#) can take one of the following values:

- `0`: The node is never used as an arbitrator.
- `1`: The node has high priority; that is, it is preferred as an arbitrator over low-priority nodes.

- **2:** Indicates a low-priority node which is used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its [ArbitrationRank](#) to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting [ArbitrationRank](#) to 0 on all management and SQL nodes, or by setting the [Arbitration](#) parameter in the [\[ndbd default\]](#) section of the [config.ini](#) global configuration file. Setting [Arbitration](#) causes any settings for [ArbitrationRank](#) to be disregarded.

- [ArbitrationDelay](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | milliseconds                |
| Default            | 0                           |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- [DataDir](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | path          |
| Default            | .             |
| Range              | ...           |
| Restart Type       | N (NDB 7.5.0) |

This specifies the directory where output files from the management server are placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the [FILE](#) parameter for [LogDestination](#) as discussed previously in this section.)

The default value for this parameter is the directory in which [ndb\\_mgmd](#) is located.

- [PortNumberStats](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | unsigned      |
| Default            | [...]         |
| Range              | 0 - 64K       |
| Restart Type       | N (NDB 7.5.0) |

This parameter specifies the port number used to obtain statistical information from an NDB Cluster management server. It has no default value.

- [Wan](#)

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.5.0 |
|                    | 3077      |

|               |               |
|---------------|---------------|
| Type or units | boolean       |
| Default       | false         |
| Range         | true, false   |
| Restart Type  | N (NDB 7.5.0) |

Use WAN TCP setting as default.

- [HeartbeatThreadPriority](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | string        |
| Default            | [...]         |
| Range              | ...           |
| Restart Type       | N (NDB 7.5.0) |

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
 {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of **FIFO** (first in, first out) or **RR** (round robin). The policy value is followed optionally by the priority (an integer).

- [ExtraSendBufferMemory](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | bytes         |
| Default            | 0             |
| Range              | 0 - 32G       |
| Restart Type       | N (NDB 7.5.0) |

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using [TotalSendBufferMemory](#), [SendBufferMemory](#), or both.

- [TotalSendBufferMemory](#)

|                    |                                |
|--------------------|--------------------------------|
| Version (or later) | NDB 7.5.0                      |
| Type or units      | bytes                          |
| Default            | 0                              |
| Range              | 256K - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                  |

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 21.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#).

- [HeartbeatIntervalMgmdMgmd](#)

|                     |                               |
|---------------------|-------------------------------|
| Version (or later)  | NDB 7.5.0                     |
| Type or units       | milliseconds                  |
| Default             | 1500                          |
| Range               | 100 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)                 |

Specify the interval between heartbeat messages used to determine whether another management node is in contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

#### Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing [config.ini](#) files. For more information about issues arising when using multiple management nodes, see [Section 21.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 21.8 NDB Cluster restart types**

| Symbol | Restart Type | Description                                                                                                                                  |
|--------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| N      | Node         | The parameter can be updated using a rolling restart (see <a href="#">Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”</a> ) |
| S      | System       | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter                                         |
| I      | Initial      | Data nodes must be restarted using the <code>--initial</code> option                                                                         |

### 21.3.3.6 Defining NDB Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or `ndbmttd` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is either one of `ExecuteOnComputer` or `HostName`; this must be defined in the local `[ndbd]` section.

The parameter `NoOfReplicas` should be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes. It is not strictly necessary to set `NoOfReplicas`, but it is good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `NodeId` and `ExecuteOnComputer` *must* be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means  $100 \times 1024 = 102400$ .)

Parameter names and values are case-insensitive, unless used in a MySQL Server `my.cnf` or `my.ini` file, in which case they are case-sensitive.

Information about configuration parameters specific to NDB Cluster Disk Data tables can be found later in this section (see [Disk Data Configuration Parameters](#)).

All of these parameters also apply to `ndbmttd` (the multithreaded version of `ndbd`). Three additional data node configuration parameters—`MaxNoOfExecutionThreads`, `ThreadConfig`, and `NoOfFragmentLogParts`—apply to `ndbmttd` only; these have no effect when used with `ndbd`. For more information, see [Multi-Threading Configuration Parameters \(ndbmttd\)](#). See also [Section 21.4.3, “ndbmttd — The NDB Cluster Data Node Daemon \(Multi-Threaded\)“](#).

**Identifying data nodes.** The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- `NodeId`

|                    |                |
|--------------------|----------------|
| Version (or later) | NDB 7.5.0      |
| Type or units      | unsigned       |
| Default            | [...]          |
| Range              | 1 - 48         |
| Restart Type       | IS (NDB 7.5.0) |

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` is the only supported parameter name to use when identifying data nodes. (`Id` was removed in NDB 7.5.0.)

- `ExecuteOnComputer`

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | name          |
| Default            | [...]         |
| Range              | ...           |
| Deprecated         | NDB 7.5.0     |
| Restart Type       | S (NDB 7.5.0) |

This refers to the `Id` set for one of the computers defined in a `[computer]` section.

### Important

This parameter is deprecated as of NDB 7.5.0, and is subject to removal in a future release. Use the `HostName` parameter instead.

- `HostName`

|                    |                    |
|--------------------|--------------------|
| Version (or later) | NDB 7.5.0          |
| Type or units      | name or IP address |
| Default            | localhost          |
| Range              | ...                |

|              |               |
|--------------|---------------|
| Restart Type | N (NDB 7.5.0) |
|--------------|---------------|

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- [ServerPort](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | unsigned      |
| Default             | [...]         |
| Range               | 1 - 64K       |
| <b>Restart Type</b> | S (NDB 7.5.0) |

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an `[ndbd]` section or (if you need to do this for multiple data nodes) the `[ndbd default]` section of the `config.ini` file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

#### Note

Connections from data nodes to management nodes is done using the `ndb_mgmd` management port (the management server's `PortNumber`) so outgoing connections to that port from any data nodes should always be permitted.

- [TcpBind\\_INADDR\\_ANY](#)

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- [NodeGroup](#)

|                     |                |
|---------------------|----------------|
| Version (or later)  | NDB 7.5.0      |
| Type or units       | unsigned       |
| Default             | [...]          |
| Range               | 0 - 65536      |
| <b>Restart Type</b> | IS (NDB 7.5.0) |

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the `[ndbd default]` section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The `NodeGroup` parameter is chiefly intended for use in adding a new node group to a running NDB Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a `NodeGroup` value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see [Section 21.5.7.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”](#).

- [LocationDomainId](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.6.4     |
| Type or units      | integer       |
| Default            | 0             |
| Range              | 0 - 16        |
| Added              | NDB 7.6.4     |
| Restart Type       | S (NDB 7.5.0) |

Assigns a data node to a specific [availability domain](#) (also known as an availability zone) within a cloud. By informing [NDB](#) which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use [NDB](#) transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

[LocationDomainId](#) takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- [NoOfReplicas](#)

|                    |                |
|--------------------|----------------|
| Version (or later) | NDB 7.5.0      |
| Type or units      | integer        |
| Default            | 2              |
| Range              | 1 - 2          |
| Restart Type       | IS (NDB 7.5.0) |

This global parameter can be set only in the [\[ndbd default\]](#) section, and defines the number of fragment replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that [NoOfReplicas](#) is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that

nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes is the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

The default and recommended maximum value for `NoOfReplicas` is 2. *This is the recommended value for most production environments.*

#### Important

While it is theoretically possible for the value of this parameter to be 3 or 4, **NDB Cluster 7.5 and NDB Cluster 7.6 do not support setting `NoOfReplicas` to a value greater than 2 in production.**

#### Warning

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The number of data nodes in the cluster must be evenly divisible by the value of this parameter. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- `DataDir`

|                     |                |
|---------------------|----------------|
| Version (or later)  | NDB 7.5.0      |
| Type or units       | path           |
| Default             | .              |
| Range               | ...            |
| <b>Restart Type</b> | IN (NDB 7.5.0) |

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- `FileSystemPath`

|                     |                |
|---------------------|----------------|
| Version (or later)  | NDB 7.5.0      |
| Type or units       | path           |
| Default             | DataDir        |
| Range               | ...            |
| <b>Restart Type</b> | IN (NDB 7.5.0) |

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

#### Note

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for NDB Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- [BackupDataDir](#)

|                     |                |
|---------------------|----------------|
| Version (or later)  | NDB 7.5.0      |
| Type or units       | path           |
| Default             | FileSystemPath |
| Range               | ...            |
| <b>Restart Type</b> | IN (NDB 7.5.0) |

This parameter specifies the directory in which backups are placed.

#### Important

The string '`/BACKUP`' is always appended to this value. For example, if you set the value of `BackupDataDir` to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the effective default backup location is the directory named `BLOCKUP` under the location specified by the `FileSystemPath` parameter.

## Data Memory, Index Memory, and String Memory

`DataMemory` and `IndexMemory` are `[ndbd]` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` and `IndexMemory` are used, as they usually need to be updated to reflect actual usage by the cluster.

#### Note

`IndexMemory` is deprecated in NDB 7.6, and subject to removal in a future version of NDB Cluster. See the descriptions that follow for further information.

- [DataMemory](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | bytes         |
| Default             | 80M           |
| Range               | 1M - 1T       |
| Version (or later)  | NDB 7.6.2     |
| Type or units       | bytes         |
| Default             | 98M           |
| Range               | 1M - 1T       |
| <b>Restart Type</b> | N (NDB 7.5.0) |

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from `DataMemory`. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is 14000 bytes.

In NDB 7.5 (and earlier), the memory space defined by [DataMemory](#) is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by [IndexMemory](#), but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by [DataMemory](#). However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify [USING HASH](#) in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name`.

In NDB 7.6, resources assigned to [DataMemory](#) are used for storing *all* data and indexes; any memory configured as [IndexMemory](#) is automatically added to that used by [DataMemory](#) to form a common resource pool.

Currently, NDB Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get [Table is full](#) errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free [DataMemory](#). This can also pose a problem with data node restarts on nodes that are heavily loaded with data.

In NDB 7.5.4 and later, you can control the number of partitions per local data manager for a given table by setting the [NDB\\_TABLE](#) option [PARTITION\\_BALANCE](#) to one of the values [FOR\\_RA\\_BY\\_LDM](#), [FOR\\_RA\\_BY\\_LDM\\_X\\_2](#), [FOR\\_RA\\_BY\\_LDM\\_X\\_3](#), or [FOR\\_RA\\_BY\\_LDM\\_X\\_4](#), for 1, 2, 3, or 4 partitions per LDM, respectively, when creating the table (see [Section 13.1.18.9, “Setting NDB\\_TABLE Options”](#)).

#### Note

In previous versions of NDB Cluster it was possible to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the [MAX\\_ROWS](#) option for [CREATE TABLE](#). While still supported for backward compatibility, using [MAX\\_ROWS](#) for this purpose is deprecated beginning with NDB 7.5.4, where you should use [PARTITION\\_BALANCE](#) instead.

You can also use the [MinFreePct](#) configuration parameter to help avoid problems with node restarts.

The memory space allocated by [DataMemory](#) consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in [NoOfReplicas](#).

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that [DataMemory](#) pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The [DataMemory](#) memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the [DataMemory](#). There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones

- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

In NDB 7.5 (and earlier), the default value for [DataMemory](#) is 80MB; beginning with NDB 7.6.2, this is 98MB. The minimum value is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- [IndexMemory](#)

|                              |               |
|------------------------------|---------------|
| Version (or later)           | NDB 7.5.0     |

| <a href="#">Restart Type</a> | N (NDB 7.5.0) |

In NDB 7.5 and earlier, this parameter controls the amount of storage used for hash indexes in NDB Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. When defining a primary key or a unique index, two indexes are created, one of which is a hash index used for all tuple accesses as well as lock handling. This index is also used to enforce unique constraints.

Beginning with NDB 7.6.2, the [IndexMemory](#) parameter is deprecated (and subject to future removal); any memory assigned to [IndexMemory](#) is allocated instead to the same pool as [DataMemory](#), which becomes solely responsible for all resources needed for storing data and indexes in memory. In NDB 7.6.2 and later, the use of [IndexMemory](#) in the cluster configuration file triggers a warning from the management server.

You can estimate the size of a hash index using this formula:

```
size = ((fragments * 32K) + (rows * 18))
 * fragment_replicas
```

*fragments* is the number of fragments, *fragment\_replicas* is the number of fragment replicas (normally two), and *rows* is the number of rows. If a table has one million rows, eight fragments, and two fragment replicas, the expected index memory usage is calculated as shown here:

```
((8 * 32K) + (1000000 * 18)) * 2 = ((8 * 32768) + (1000000 * 18)) * 2
= (262144 + 18000000) * 2
= 18262144 * 2 = 36524288 bytes = ~35MB
```

Index statistics for ordered indexes (when these are enabled) are stored in the [mysql.ndb\\_index\\_stat\\_sample](#) table. Since this table has a hash index, this adds to index

memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

```
sample_size= key_size + ((key_attributes + 1) * 4)

sample_rows = IndexStatSaveSize
 * ((0.01 * IndexStatSaveScale * log2(rows * sample_size)) + 1)
 / sample_size
```

In the preceding formula, `key_size` is the size of the ordered index key in bytes, `key_attributes` is the number of attributes in the ordered index key, and `rows` is the number of rows in the base table.

Assume that table `t1` has 1 million rows and an ordered index named `ix1` on two four-byte integers. Assume in addition that `IndexStatSaveSize` and `IndexStatSaveScale` are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

```
sample_size = 8 + ((1 + 2) * 4) = 20 bytes

sample_rows = 32K
 * ((0.01 * 100 * log2(1000000*20)) + 1)
 / 20
 = 32768 * ((1 * ~16.811) +1) / 20
 = 32768 * ~17.811 / 20
 = ~29182 rows
```

The expected index memory usage is thus  $2 * 18 * 29182 = \sim 1050550$  bytes.

Prior to NDB 7.6.2, the default value for `IndexMemory` is 18MB and the minimum is 1 MB; in NDB 7.6.2 and later, the minimum and default value for this parameter is 0 (zero). This has implications for downgrades from NDB 7.6 to earlier versions of NDB Cluster; see [Section 21.2.7, “Upgrading and Downgrading NDB Cluster”](#), for more information.

- [StringMemory](#)

|                              |                             |

| Range                        | 0 - 4294967039 (0xFFFFFEFF) |
| <a href="#">Restart Type</a> | S (NDB 7.5.0)               |

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[ndbd]` or `[ndbd default]` section of the `config.ini` file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, `MaxNoOfTriggers`, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many NDB tables (1000 or more), it is possible to get Error 773 `Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error`, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
 a INT NOT NULL,
```

```

b INT NOT NULL,
c INT NOT NULL,
PRIMARY KEY(a),
UNIQUE(b)
) ENGINE=NDBCLUSTER;

```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns `a` and `b` consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in NDB Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two fragment replicas, there are two node groups. Thus, the total data memory available is  $2 \times \text{DataMemory}$  for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` (and in NDB 7.5 and earlier `IndexMemory`) can be changed, but decreasing it can be risky; doing so can easily lead to a node or even an entire NDB Cluster that is unable to restart due to there being insufficient memory space. Increases should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

**MinFreePct.** A proportion (5% by default) of data node resources including `DataMemory` (and in NDB 7.5 and earlier, `IndexMemory`) is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the `MinFreePct` data node configuration parameter (default 5).

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | unsigned      |
| Default            | 5             |
| Range              | 0 - 100       |
| Restart Type       | N (NDB 7.5.0) |

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.** The next few `[ndbd]` parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially [MaxNoOfConcurrentOperations](#)) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

[MaxDMLOperationsPerTransaction](#) sets the maximum number of DML operations that can be performed in a given transaction.

- [MaxNoOfConcurrentTransactions](#)

|                              |                              |

| Deprecated                   | Yes (in NDB 8.0)             |
| <a href="#">Restart Type</a> | N (NDB 7.5.0)                |

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as

```
TotalNoOfConcurrentTransactions =
 (maximum number of tables accessed in any single transaction + 1)
 * number of SQL nodes
```

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then  $10 * 11 = 110$  transaction records are required for this transaction, per MySQL server, or  $110 * 10 = 1100$  transaction records total. Each data node can be expected to handle `TotalNoOfConcurrentTransactions / number of data nodes`. For an NDB Cluster having 4 data nodes, this would mean setting [MaxNoOfConcurrentTransactions](#) on each data node to  $1100 / 4 = 275$ . In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's `MaxNoOfConcurrentTransactions` is sufficient to cover a number of transactions equal to `TotalNoOfConcurrentTransactions / number of node groups`. If this cluster has a single node group, then [MaxNoOfConcurrentTransactions](#) should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for [MaxNoOfConcurrentTransactions](#) should always be no more than the value of [MaxNoOfConcurrentOperations](#).

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- [MaxNoOfConcurrentOperations](#)

|                    |                              |
|--------------------|------------------------------|
| Version (or later) | NDB 7.5.0                    |
| Type or units      | integer                      |
| Default            | 32K                          |
| Range              | 32 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                |

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to  $1000000 / 4 = 250000$ . To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to [total number of concurrent operations / number of node groups](#). (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of [MaxNoOfConcurrentOperations](#) should always be greater than or equal to the value of [MaxNoOfConcurrentTransactions](#).

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. [MaxNoOfConcurrentOperations](#) is always used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- [MaxNoOfLocalOperations](#)

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.5.0 |
|--------------------|-----------|

|                     |                              |
|---------------------|------------------------------|
| Type or units       | integer                      |
| Default             | UNDEFINED                    |
| Range               | 32 - 4294967039 (0xFFFFFEFF) |
| Deprecated          | Yes (in NDB 8.0)             |
| <b>Restart Type</b> | N (NDB 7.5.0)                |

By default, this parameter is calculated as  $1.1 \times \text{MaxNoOfConcurrentOperations}$ . This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

- [MaxDMLOperationsPerTransaction](#)

|                     |                  |
|---------------------|------------------|
| Version (or later)  | NDB 7.5.0        |
| Type or units       | operations (DML) |
| Default             | 4294967295       |
| Range               | 32 - 4294967295  |
| <b>Restart Type</b> | N (NDB 7.5.0)    |

This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you can set [MaxDMLOperationsPerTransaction](#) to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

**Transaction temporary storage.** The next set of [\[ndbd\]](#) parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- [MaxNoOfConcurrentIndexOperations](#)

|                     |                             |
|---------------------|-----------------------------|
| Version (or later)  | NDB 7.5.0                   |
| Type or units       | integer                     |
| Default             | 8K                          |
| Range               | 0 - 4294967039 (0xFFFFFEFF) |
| Deprecated          | Yes (in NDB 8.0)            |
| <b>Restart Type</b> | N (NDB 7.5.0)               |

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter [MaxNoOfConcurrentOperations](#).

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- [MaxNoOfFiredTriggers](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | integer                     |
| Default            | 4000                        |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Deprecated         | Yes (in NDB 8.0)            |
| Restart Type       | N (NDB 7.5.0)               |

The default value of [MaxNoOfFiredTriggers](#) is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- [TransactionBufferMemory](#)

|                    |                              |
|--------------------|------------------------------|
| Version (or later) | NDB 7.5.0                    |
| Type or units      | bytes                        |
| Default            | 1M                           |
| Range              | 1K - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                |

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for [TransactionBufferMemory](#) is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter [ZATTRBUF\\_FILESIZE](#) (found in [ndb/src/kernel/blocks/Dbtc/Dbtc.hpp](#)) set to  $4000 \times 128$  bytes (500KB). A similar buffer for key information, [ZDATABUF\\_FILESIZE](#) (also in [Dbtc.hpp](#)) contains  $4000 \times 16 = 62.5$ KB of buffer space. [Dbtc](#) is the module that handles transaction coordination.

**Scans and buffering.** There are additional [\[ndbd\]](#) parameters in the [Dblqh](#) module (in [ndb/src/kernel/blocks/Dblqh/Dblqh.hpp](#)) that affect reads and updates. These include [ZATTRINBUF\\_FILESIZE](#), set by default to  $10000 \times 128$  bytes (1250KB) and [ZDATABUF\\_FILE\\_SIZE](#), set by default to  $10000 \times 16$  bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- [BatchSizePerLocalScan](#)

|                    |                  |
|--------------------|------------------|
| Version (or later) | NDB 7.5.0        |
| Type or units      | integer          |
| Default            | 256              |
| Range              | 1 - 992          |
| Deprecated         | Yes (in NDB 8.0) |

|                              |               |
|------------------------------|---------------|
| <a href="#">Restart Type</a> | N (NDB 7.5.0) |
|------------------------------|---------------|

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

[BatchSizePerLocalScan](#) has a strong connection to the [BatchSize](#) defined in the SQL nodes.

- [LongMessageBuffer](#)

|                              |                                |
|------------------------------|--------------------------------|
| Version (or later)           | NDB 7.5.0                      |
| Type or units                | bytes                          |
| Default                      | 64M                            |
| Range                        | 512K - 4294967039 (0xFFFFFEFF) |
| <a href="#">Restart Type</a> | N (NDB 7.5.0)                  |

This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB.

This parameter seldom needs to be changed from the default.

- [MaxFKBuildBatchSize](#)

|                              |               |
|------------------------------|---------------|
| Version (or later)           | NDB 7.6.4     |
| Type or units                | integer       |
| Default                      | 64            |
| Range                        | 16 - 512      |
| Added                        | NDB 7.6.4     |
| <a href="#">Restart Type</a> | N (NDB 7.5.0) |

Maximum scan batch size used for building foreign keys. Increasing the value set for this parameter may speed up building of foreign key builds at the expense of greater impact to ongoing traffic.

Added in NDB 7.6.4

- [MaxNumberOfConcurrentScans](#)

|                              |               |
|------------------------------|---------------|
| Version (or later)           | NDB 7.5.0     |
| Type or units                | integer       |
| Default                      | 256           |
| Range                        | 2 - 500       |
| <a href="#">Restart Type</a> | N (NDB 7.5.0) |

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain [MaxNumberOfConcurrentScans](#) scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is

an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of `MaxNoOfConcurrentScans` is 256. The maximum value is 500.

- `MaxNoOfLocalScans`

|                    |                                                                      |
|--------------------|----------------------------------------------------------------------|
| Version (or later) | NDB 7.5.0                                                            |
| Type or units      | integer                                                              |
| Default            | $4 * \text{MaxNoOfConcurrentScans} * [\# \text{ of data nodes}] + 2$ |
| Range              | 32 - 4294967039 (0xFFFFFEFF)                                         |
| Deprecated         | Yes (in NDB 8.0)                                                     |
| Restart Type       | N (NDB 7.5.0)                                                        |

Specifies the number of local scan records if many scans are not fully parallelized. When the number of local scan records is not provided, it is calculated as shown here:

```
4 * MaxNoOfConcurrentScans * [# data nodes] + 2
```

The minimum value is 32.

- `MaxParallelCopyInstances`

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | integer       |
| Default            | 0             |
| Range              | 0 - 64        |
| Restart Type       | N (NDB 7.5.0) |

This parameter sets the parallelization used in the copy phase of a node restart or system restart, when a node that is currently just starting is synchronised with a node that already has current data by copying over any changed records from the node that is up to date. Because full parallelism in such cases can lead to overload situations, `MaxParallelCopyInstances` provides a means to decrease it. This parameter's default value 0. This value means that the effective parallelism is equal to the number of LDM instances in the node just starting as well as the node updating it.

- `MaxParallelScansPerFragment`

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | bytes                       |
| Default            | 256                         |
| Range              | 1 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

It is possible to configure the maximum number of parallel scans (`TUP` scans and `TUX` scans) allowed before they begin queuing for serial handling. You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

- `MaxReorgBuildBatchSize`

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.6.4 |
| Type or units      | integer   |
| Default            | 64        |

|                     |               |
|---------------------|---------------|
| Range               | 16 - 512      |
| Added               | NDB 7.6.4     |
| <b>Restart Type</b> | N (NDB 7.5.0) |

Maximum scan batch size used for reorganization of table partitions. Increasing the value set for this parameter may speed up reorganization at the expense of greater impact to ongoing traffic.

Added in NDB 7.6.4

- [MaxUIBuildBatchSize](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.6.4     |
| Type or units       | integer       |
| Default             | 64            |
| Range               | 16 - 512      |
| Added               | NDB 7.6.4     |
| <b>Restart Type</b> | N (NDB 7.5.0) |

Maximum scan batch size used for building unique keys. Increasing the value set for this parameter may speed up such builds at the expense of greater impact to ongoing traffic.

Added in NDB 7.6.4

## Memory Allocation

### [MaxAllocate](#)

|                     |                  |
|---------------------|------------------|
| Version (or later)  | NDB 7.5.0        |
| Type or units       | unsigned         |
| Default             | 32M              |
| Range               | 1M - 1G          |
| Deprecated          | Yes (in NDB 8.0) |
| <b>Restart Type</b> | N (NDB 7.5.0)    |

This parameter was used in older versions of NDB Cluster, but has no effect in NDB 7.5 or NDB 7.6.

## Hash Map Size

### [DefaultHashMapSize](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | LDM threads   |
| Default             | 240           |
| Range               | 0 - 3840      |
| <b>Restart Type</b> | N (NDB 7.5.0) |

The size of the table hash maps used by [NDB](#) is configurable using this parameter. [DefaultHashMapSize](#) can take any of three possible values (0, 240, 3840).

The original intended use for this parameter was to facilitate upgrades and especially downgrades to and from very old releases with differing default hash map sizes. This is not an issue when upgrading from NDB Cluster 7.3 (or later) to later versions.

Decreasing this parameter online after any tables have been created or modified with [DefaultHashMapSize](#) equal to 3840 is not supported.

**Logging and checkpointing.** The following `[ndbd]` parameters control log and checkpoint behavior.

- `FragmentLogFileSize`

|                    |                |
|--------------------|----------------|
| Version (or later) | NDB 7.5.0      |
| Type or units      | bytes          |
| Default            | 16M            |
| Range              | 4M - 1G        |
| Restart Type       | IN (NDB 7.5.0) |

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when NDB Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

For more information about fragment log files, see the description for `NoOfFragmentLogFile`s.

- `InitialNoOfOpenFiles`

|                    |                              |
|--------------------|------------------------------|
| Version (or later) | NDB 7.5.0                    |
| Type or units      | files                        |
| Default            | 27                           |
| Range              | 20 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                |

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- `InitFragmentLogFile`s

|                    |                |
|--------------------|----------------|
| Version (or later) | NDB 7.5.0      |
| Type or units      | [see values]   |
| Default            | SPARSE         |
| Range              | SPARSE, FULL   |
| Restart Type       | IN (NDB 7.5.0) |

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. `InitFragmentLogFile`s takes either of two values:

- `SPARSE`. Fragment log files are created sparsely. This is the default value.
- `FULL`. Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting `InitFragmentLogFile=FULL` may help eliminate I/O errors on writes to the REDO log.

- `EnablePartialLcp`

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.6.4 |
|--------------------|-----------|

|                     |               |
|---------------------|---------------|
| Type or units       | boolean       |
| Default             | true          |
| Range               | ...           |
| Added               | NDB 7.6.4     |
| <b>Restart Type</b> | N (NDB 7.5.0) |

When `true`, enable partial local checkpoints: This means that each LCP records only part of the full database, plus any records containing rows changed since the last LCP; if no rows have changed, the LCP updates only the LCP control file and does not update any data files.

If `EnablePartialLcp` is disabled (`false`), each LCP uses only a single file and writes a full checkpoint; this requires the least amount of disk space for LCPs, but increases the write load for each LCP. The default value is enabled (`true`). The proportion of space used by partial LCPs can be modified by the setting for the `RecoveryWork` configuration parameter.

For more information about files and directories used for full and partial LCPs, see [NDB Cluster Data Node File System Directory](#).

In NDB 7.6.7 and later, setting this parameter to `false` also disables the calculation of disk write speed used by the adaptive LCP control mechanism.

- [LcpScanProgressTimeout](#)

|                     |                             |
|---------------------|-----------------------------|
| Version (or later)  | NDB 7.5.0                   |
| Type or units       | second                      |
| Default             | 60                          |
| Range               | 0 - 4294967039 (0xFFFFFFFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)               |

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. This interval can be set using the `LcpScanProgressTimeout` data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

- [MaxNoOfOpenFiles](#)

|                     |                              |
|---------------------|------------------------------|
| Version (or later)  | NDB 7.5.0                    |
| Type or units       | unsigned                     |
| Default             | 0                            |
| Range               | 20 - 4294967039 (0xFFFFFFFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)                |

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- [MaxNoOfSavedMessages](#)

|                    |           |      |
|--------------------|-----------|------|
| Version (or later) | NDB 7.5.0 | 3097 |
|--------------------|-----------|------|

|               |                             |
|---------------|-----------------------------|
| Type or units | integer                     |
| Default       | 25                          |
| Range         | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type  | N (NDB 7.5.0)               |

This parameter sets the maximum number of errors written in the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

- [MaxLCPStartDelay](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | seconds       |
| Default            | 0             |
| Range              | 0 - 600       |
| Restart Type       | N (NDB 7.5.0) |

In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set [MaxLCPStartDelay](#), which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the [config.ini](#) file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

- [NoOfFragmentLogFile](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | integer                     |
| Default            | 16                          |
| Range              | 3 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | IN (NDB 7.5.0)              |

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A [REDO](#) log record is not removed until both required local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the [FragmentLogFileSize](#)

parameter. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFile`s may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (`Out of log file space temporarily`). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

### Important

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).

- [RecoveryWork](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.6.4     |
| Type or units       | integer       |
| Default             | 50            |
| Range               | 25 - 100      |
| Version (or later)  | NDB 7.6.5     |
| Type or units       | integer       |
| Default             | 60            |
| Range               | 25 - 100      |
| Added               | NDB 7.6.4     |
| <b>Restart Type</b> | N (NDB 7.5.0) |

Percentage of storage overhead for LCP files. This parameter has an effect only when `EnablePartialLcp` is true, that is, only when partial local checkpoints are enabled. A higher value means:

- Fewer records are written for each LCP, LCPs use more space
- More work is needed during restarts

A lower value for `RecoveryWork` means:

- More records are written during each LCP, but LCPs require less space on disk.
- Less work during restart and thus faster restarts, at the expense of more work during normal operations

For example, setting `RecoveryWork` to 60 means that the total size of an LCP is roughly  $1 + 0.6 = 1.6$  times the size of the data to be checkpointed. This means that 60% more work is required during the restore phase of a restart compared to the work done during a restart that uses full checkpoints. (This is more than compensated for during other phases of the restart such that the restart as a whole is still faster when using partial LCPs than when using full LCPs.) In order not to fill up the redo log, it is necessary to write at  $1 + (1 / \text{RecoveryWork})$  times the rate of data changes during checkpoints—thus, when `RecoveryWork` = 60, it is necessary to write at approximately  $1 + (1 / 0.6) = 1.67$ .

= 2.67 times the change rate. In other words, if changes are being written at 10 MByte per second, the checkpoint needs to be written at roughly 26.7 MByte per second.

Setting `RecoveryWork` = 40 means that only 1.4 times the total LCP size is needed (and thus the restore phase takes 10 to 15 percent less time. In this case, the checkpoint write rate is 3.5 times the rate of change.

The NDB source distribution includes a test program for simulating LCPs. `lcp_simulator.cc` can be found in `storage/ndb/src/kernel/blocks/backup/`. To compile and run it on Unix platforms, execute the commands shown here:

```
shell> gcc lcp_simulator.cc
shell> ./a.out
```

This program has no dependencies other than `stdio.h`, and does not require a connection to an NDB cluster or a MySQL server. By default, it simulates 300 LCPs (three sets of 100 LCPs, each consisting of inserts, updates, and deletes, in turn), reporting the size of the LCP after each one. You can alter the simulation by changing the values of `recovery_work`, `insert_work`, and `delete_work` in the source and recompiling. For more information, see the source of the program.

- [InsertRecoveryWork](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.6.5     |
| Type or units      | integer       |
| Default            | 40            |
| Range              | 0 - 70        |
| Added              | NDB 7.6.5     |
| Restart Type       | N (NDB 7.5.0) |

Percentage of `RecoveryWork` used for inserted rows. A higher value increases the number of writes during a local checkpoint, and decreases the total size of the LCP. A lower value decreases the number of writes during an LCP, but results in more space being used for the LCP, which means that recovery takes longer. This parameter has an effect only when `EnablePartialLcp` is true, that is, only when partial local checkpoints are enabled.

- [EnableRedoControl](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.6.7     |
| Type or units      | boolean       |
| Default            | false         |
| Range              | ...           |
| Added              | NDB 7.6.7     |
| Restart Type       | N (NDB 7.5.0) |

Enable adaptive checkpointing speed for controlling redo log usage. Set to `false` to disable (the default). Setting `EnablePartialLcp` to `false` also disables the adaptive calculation.

When enabled, `EnableRedoControl` allows the data nodes greater flexibility with regard to the rate at which they write LCPs to disk. More specifically, enabling this parameter means that higher write rates can be employed, so that LCPs can complete and Redo logs be trimmed more quickly, thereby reducing recovery time and disk space requirements. This functionality allows data nodes to make better use of the higher rate of I/O and greater bandwidth available from modern solid-

state storage devices and protocols, such as solid-state drives (SSDs) using Non-Volatile Memory Express (NVMe).

The parameter currently defaults to `false` (disabled) due to the fact that NDB is still deployed widely on systems whose I/O or bandwidth is constrained relative to those employing solid-state technology, such as those using conventional hard disks (HDDs). In settings such as these, the `EnableRedoControl` mechanism can easily cause the I/O subsystem to become saturated, increasing wait times for data node input and output. In particular, this can cause issues with NDB Disk Data tables which have tablespaces or log file groups sharing a constrained IO subsystem with data node LCP and redo log files; such problems potentially include node or cluster failure due to GCP stop errors.

**Metadata objects.** The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters.

#### Note

These act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- `MaxNoOfAttributes`

|                    |                              |
|--------------------|------------------------------|
| Version (or later) | NDB 7.5.0                    |
| Type or units      | integer                      |
| Default            | 1000                         |
| Range              | 32 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                |

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like `MaxNoOfTables`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfAttributes` attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the NDB Cluster table having the greatest number of attributes (`greatest_number_of_attributes`) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be  $6 * greatest\_number\_of\_attributes = 600$ .

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfTables`. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

- `MaxNoOfTables`

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | integer       |
| Default            | 128           |
| Range              | 8 - 20320     |
| Restart Type       | N (NDB 7.5.0) |

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like [MaxNoOfAttributes](#), it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than [MaxNoOfTables](#) tables.)

For each attribute that has a [BLOB](#) data type an extra table is used to store most of the [BLOB](#) data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

#### Note

The sum of [MaxNoOfTables](#), [MaxNoOfOrderedIndexes](#), and [MaxNoOfUniqueHashIndexes](#) must not exceed  $2^{32} - 2$  (4294967294).

- [MaxNoOfOrderedIndexes](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | integer                     |
| Default            | 128                         |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. [MaxNoOfOrderedIndexes](#) sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

#### Note

The sum of [MaxNoOfTables](#), [MaxNoOfOrderedIndexes](#), and [MaxNoOfUniqueHashIndexes](#) must not exceed  $2^{32} - 2$  (4294967294).

- [MaxNoOfUniqueHashIndexes](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | integer                     |
| Default            | 64                          |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |

|              |               |
|--------------|---------------|
| Restart Type | N (NDB 7.5.0) |
|--------------|---------------|

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

#### Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed  $2^{32} - 2$  (4294967294).

- [MaxNoOfTriggers](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | integer                     |
| Default            | 768                         |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- [MaxNoOfSubscriptions](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | unsigned                    |
| Default            | 0                           |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

Each NDB table in an NDB Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for `MaxNoOfSubscriptions` is 0, which is treated as equal to `MaxNoOfTables`. Each subscription consumes 108 bytes.

- [MaxNoOfSubscribers](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | unsigned                    |
| Default            | 0                           |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |

|              |               |
|--------------|---------------|
| Restart Type | N (NDB 7.5.0) |
|--------------|---------------|

This parameter is of interest only when using NDB Cluster Replication. The default value is 0, which is treated as `2 * MaxNoOfTables`; that is, there is one subscription per NDB table for each of two MySQL servers (one acting as the replication source and the other as the replica). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-source replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three NDB Cluster s, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a source and as a replica, you should set `MaxNoOfSubscribers` equal to `3 * MaxNoOfTables`.

For more information, see [Section 21.6, “NDB Cluster Replication”](#).

- [MaxNoOfConcurrentSubOperations](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | unsigned                    |
| Default            | 256                         |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

**Boolean parameters.** The behavior of data nodes is also affected by a set of `[ndbd]` parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- [CompressedLCP](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | boolean       |
| Default            | false         |
| Range              | true, false   |
| Restart Type       | N (NDB 7.5.0) |

Setting this parameter to `1` causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

#### Important

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

- [CrashOnCorruptedTuple](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | boolean       |
| Default             | true          |
| Range               | true, false   |
| <b>Restart Type</b> | N (NDB 7.5.0) |

When this parameter is enabled, it forces a data node to shut down whenever it encounters a corrupted tuple. In NDB 7.5, it is enabled by default.

- [Diskless](#)

|                     |                  |
|---------------------|------------------|
| Version (or later)  | NDB 7.5.0        |
| Type or units       | true false (1 0) |
| Default             | false            |
| Range               | true, false      |
| <b>Restart Type</b> | IS (NDB 7.5.0)   |

It is possible to specify NDB Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

**Important**

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

[Diskless](#) is disabled by default.

- [LateAlloc](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | numeric       |
| Default             | 1             |
| Range               | 0 - 1         |
| <b>Restart Type</b> | N (NDB 7.5.0) |

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

- [LockPagesInMainMemory](#)

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.5.0 |
| Type or units      | numeric   |
| Default            | 0         |
| Range              | 0 - 2     |

|              |               |
|--------------|---------------|
| Restart Type | N (NDB 7.5.0) |
|--------------|---------------|

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This parameter takes one of the integer values [0](#), [1](#), or [2](#), which act as shown in the following list:

- [0](#): Disables locking. This is the default value.
- [1](#): Performs the lock after allocating memory for the process.
- [2](#): Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root.

([LockPagesInMainMemory](#) uses the `mlockall` function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by [max locked memory](#). For more information, see [ulimit -l](#) and <http://linux.die.net/man/2/mlock>).

#### Note

In older NDB Cluster releases, this parameter was a Boolean. [0](#) or [false](#) was the default setting, and disabled locking. [1](#) or [true](#) enabled locking of the process after its memory was allocated. NDB Cluster 7.5 treats [true](#) or [false](#) for the value of this parameter as an error.

#### Important

Beginning with [glibc](#) 2.10, [glibc](#) uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The [glibc](#) behavior is intended to be configurable via the [MALLOC\\_ARENA\\_MAX](#) environment variable, but a bug in this mechanism prior to [glibc](#) 2.16 meant that this variable could not be set to less than 8, so that the wasted memory could not be reclaimed. (Bug #15907219; see also [http://sourceware.org/bugzilla/show\\_bug.cgi?id=13137](http://sourceware.org/bugzilla/show_bug.cgi?id=13137) for more information concerning this issue.)

One possible workaround for this problem is to use the [LD\\_PRELOAD](#) environment variable to preload a [jemalloc](#) memory allocation library to take the place of that supplied with [glibc](#).

- [ODirect](#)

|                    |                          |
|--------------------|--------------------------|
| Version (or later) | NDB 7.5.0                |
| Type or units      | boolean                  |
| Default            | <code>false</code>       |
| Range              | <code>true, false</code> |

|                     |               |
|---------------------|---------------|
| <b>Restart Type</b> | N (NDB 7.5.0) |
|---------------------|---------------|

Enabling this parameter causes NDB to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using NDB Cluster on Linux, enable `ODirect` if you are using a 2.6 or later kernel.

`ODirect` is disabled by default.

- `ODirectSyncFlag`

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.6.4     |
| Type or units       | boolean       |
| Default             | false         |
| Range               | true, false   |
| Added               | NDB 7.6.4     |
| <b>Restart Type</b> | N (NDB 7.5.0) |

When this parameter is enabled, redo log writes are performed such that each completed file system write is handled as a call to `fsync`. The setting for this parameter is ignored if at least one of the following conditions is true:

- `ODirect` is not enabled.
- `InitFragmentLogFile`s is set to `SPARSE`.

Disabled by default.

- `RestartOnErrorInsert`

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | error code    |
| Default             | 2             |
| Range               | 0 - 4         |
| <b>Restart Type</b> | N (NDB 7.5.0) |

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- `StopOnError`

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | boolean       |
| Default             | 1             |
| Range               | 0, 1          |
| <b>Restart Type</b> | N (NDB 7.5.0) |

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is 1; this means that, by default, an error causes the data node process to halt.

When an error is encountered and `StopOnError` is 0, the data node process is restarted.

Prior to NDB Cluster 7.5.5, if the data node process exits in an uncontrolled fashion (due, for example, to performing `kill -9` on the data node process while performing a query, or to a segmentation fault), and `StopOnError` is set to 0, the angel process attempts to restart it in exactly the same way as it was started previously—that is, using the same startup options that were employed the last time the node was started. Thus, if the data node process was originally started using the `--initial` option, it is also restarted with `--initial`. This means that, in such cases, if the failure occurs on a sufficient number of data nodes in a very short interval, the effect is the same as if you had performed an initial restart of the entire cluster, leading to loss of all data. This issue is resolved in NDB Cluster 7.5.5 and later NDB 7.5 releases (Bug #83510, Bug #24945638).

Users of MySQL Cluster Manager should note that, when `StopOnError` equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See [Starting and Stopping the Agent on Linux](#), for more information.

- [UseShm](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.6.6     |
| Type or units      | boolean       |
| Default            | false         |
| Range              | true, false   |
| Added              | NDB 7.6.6     |
| Restart Type       | N (NDB 7.5.0) |

Use shared memory connections between this data node and the API node also running on this host. Set to 1 to enable.

See [Section 21.3.3.12, “NDB Cluster Shared Memory Connections”](#), for more information.

## Controlling Timeouts, Intervals, and Disk Paging

There are a number of `[ndbd]` parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- [TimeBetweenWatchDogCheck](#)

|                    |                              |
|--------------------|------------------------------|
| Version (or later) | NDB 7.5.0                    |
| Type or units      | milliseconds                 |
| Default            | 6000                         |
| Range              | 70 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                |

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- [TimeBetweenWatchDogCheckInitial](#)

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.5.0 |
|--------------------|-----------|

|               |                              |
|---------------|------------------------------|
| Type or units | milliseconds                 |
| Default       | 6000                         |
| Range         | 70 - 4294967039 (0xFFFFFEFF) |
| Restart Type  | N (NDB 7.5.0)                |

This is similar to the [TimeBetweenWatchDogCheck](#) parameter, except that [TimeBetweenWatchDogCheckInitial](#) controls the amount of time that passes between execution checks inside a storage node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

- [StartPartialTimeout](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | milliseconds                |
| Default            | 30000                       |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- [StartPartitionedTimeout](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | milliseconds                |
| Default            | 60000                       |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Version (or later) | NDB 7.6.4                   |
| Type or units      | milliseconds                |
| Default            | 0                           |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

If the cluster is ready to start after waiting for [StartPartialTimeout](#) milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If [StartPartitionedTimeout](#) is set to 0, the cluster waits indefinitely ( $2^{32}-1$  ms, or approximately 49.71 days).

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value beginning with NDB 7.6.4 is 0; previously it was 60000 (60 seconds).

- [StartFailureTimeout](#)

|                    |              |
|--------------------|--------------|
| Version (or later) | NDB 7.5.0    |
| Type or units      | milliseconds |

|              |                             |
|--------------|-----------------------------|
| Default      | 0                           |
| Range        | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.5.0)               |

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- [StartNoNodeGroupTimeout](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | milliseconds                |
| Default            | 15000                       |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

When a data node is configured with `Nodegroup = 65536`, is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodegroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is `15000` (that is, the management server waits 15 seconds). Setting this parameter equal to `0` means that the cluster waits indefinitely.

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

See [Section 21.5.7, “Adding NDB Cluster Data Nodes Online”](#), for more information.

- [HeartbeatIntervalDbDb](#)

|                    |                              |
|--------------------|------------------------------|
| Version (or later) | NDB 7.5.0                    |
| Type or units      | milliseconds                 |
| Default            | 5000                         |
| Range              | 10 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                |

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. Heartbeats cannot be disabled.

After missing four heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is five times the heartbeat interval.

The default heartbeat interval is 5000 milliseconds (5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node is declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also [Network communication and latency](#), as well as the description of the `ConnectCheckIntervalDelay` configuration parameter.

- [HeartbeatIntervalDbApi](#)

|                     |                               |
|---------------------|-------------------------------|
| Version (or later)  | NDB 7.5.0                     |
| Type or units       | milliseconds                  |
| Default             | 1500                          |
| Range               | 100 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)                 |

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for [HeartbeatIntervalDbDb](#).

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see [Network communication and latency](#).

- [HeartbeatOrder](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | numeric       |
| Default             | 0             |
| Range               | 0 - 65535     |
| <b>Restart Type</b> | S (NDB 7.5.0) |

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster. .

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers [host1](#) and [host2](#), and that these data nodes make up 2 node groups, as shown in the following table:

**Table 21.9 Four data nodes A, B, C, D running on two host computers host1, host2; each data node belongs to one of two node groups.**

| Node Group    | Nodes Running on <a href="#">host1</a> | Nodes Running on <a href="#">host2</a> |
|---------------|----------------------------------------|----------------------------------------|
| Node Group 0: | Node A                                 | Node B                                 |

| Node Group    | Nodes Running on host1 | Nodes Running on host2 |
|---------------|------------------------|------------------------|
| Node Group 1: | Node C                 | Node D                 |

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The [HeartbeatOrder](#) configuration parameter makes the order of heartbeat transmission user-configurable. The default value for [HeartbeatOrder](#) is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by [NDB](#). If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their [HeartbeatOrder](#) values from lowest to highest (and then directly from the data node having the highest [HeartbeatOrder](#) to the data node having the lowest value, to complete the circle). The values need not be consecutive. For example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the [HeartbeatOrder](#) values as shown here:

**Table 21.10 HeartbeatOrder values to force a heartbeat transition order of A->B->D->C->A.**

| Node | HeartbeatOrder Value |
|------|----------------------|
| A    | 10                   |
| B    | 20                   |
| C    | 30                   |
| D    | 25                   |

To use this parameter to change the heartbeat transmission order in a running NDB Cluster, you must first set [HeartbeatOrder](#) for each data node in the cluster in the global configuration ([config.ini](#)) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts.*

You can use [DUMP 908](#) to observe the effect of this parameter in the data node logs.

- [ConnectCheckIntervalDelay](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | milliseconds                |
| Default            | 0                           |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |

|              |               |
|--------------|---------------|
| Restart Type | N (NDB 7.5.0) |
|--------------|---------------|

This parameter enables connection checking between data nodes after one of them has failed heartbeat checks for 5 intervals of up to [HeartbeatIntervalDbDb](#) milliseconds.

Such a data node that further fails to respond within an interval of [ConnectCheckIntervalDelay](#) milliseconds is considered suspect, and is considered dead after two such intervals. This can be useful in setups with known latency issues.

The default value for this parameter is 0 (disabled).

- [TimeBetweenLocalCheckpoints](#)

|                    |                                             |
|--------------------|---------------------------------------------|
| Version (or later) | NDB 7.5.0                                   |
| Type or units      | number of 4-byte words, as base-2 logarithm |
| Default            | 20                                          |
| Range              | 0 - 31                                      |
| Restart Type       | N (NDB 7.5.0)                               |

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB ( $4 \times 2^{20}$ ) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting [TimeBetweenLocalCheckpoints](#) to 6 or less means that local checkpoints are executed continuously without pause, independent of the cluster's workload.

- [TimeBetweenGlobalCheckpoints](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | milliseconds  |
| Default            | 2000          |
| Range              | 20 - 32000    |
| Restart Type       | N (NDB 7.5.0) |

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- [TimeBetweenGlobalCheckpointsTimeout](#)

|                     |                              |
|---------------------|------------------------------|
| Version (or later)  | NDB 7.5.0                    |
| Type or units       | milliseconds                 |
| Default             | 120000                       |
| Range               | 10 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)                |

This parameter defines the minimum timeout between global checkpoints. The default is 120000 milliseconds.

- [TimeBetweenEpochs](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | milliseconds  |
| Default             | 100           |
| Range               | 0 - 32000     |
| <b>Restart Type</b> | N (NDB 7.5.0) |

This parameter defines the interval between synchronization epochs for NDB Cluster Replication. The default value is 100 milliseconds.

[TimeBetweenEpochs](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

- [TimeBetweenEpochsTimeout](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | milliseconds  |
| Default             | 0             |
| Range               | 0 - 256000    |
| <b>Restart Type</b> | N (NDB 7.5.0) |

This parameter defines a timeout for synchronization epochs for NDB Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. The default value is 0; in other words, the timeout is disabled.

[TimeBetweenEpochsTimeout](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

- [MaxBufferedEpochs](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | epochs        |
| Default             | 100           |
| Range               | 0 - 100000    |
| <b>Restart Type</b> | N (NDB 7.5.0) |

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the NDB client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- [MaxBufferedEpochBytes](#)

|                    |                                                 |
|--------------------|-------------------------------------------------|
| Version (or later) | NDB 7.5.0                                       |
| Type or units      | bytes                                           |
| Default            | 26214400                                        |
| Range              | 26214400 (0x01900000) - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                                   |

The total number of bytes allocated for buffering epochs by this node.

- [TimeBetweenInactiveTransactionAbortCheck](#)

|                    |                                |
|--------------------|--------------------------------|
| Version (or later) | NDB 7.5.0                      |
| Type or units      | milliseconds                   |
| Default            | 1000                           |
| Range              | 1000 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                  |

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction is checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- [TransactionInactiveTimeout](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | milliseconds                |
| Default            | 4294967039 (0xFFFFFEFF)     |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is [4G](#) (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. Setting it to 0 means that the application never times out. The unit is milliseconds.

- [TransactionDeadlockDetectionTimeout](#)

|                     |                              |
|---------------------|------------------------------|
| Version (or later)  | NDB 7.5.0                    |
| Type or units       | milliseconds                 |
| Default             | 1200                         |
| Range               | 50 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)                |

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. This parameter sets the amount of time that the transaction can spend executing within a data node, that is, the time that the transaction coordinator waits for each data node participating in the transaction to execute a request.

A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.

- [DiskSyncSize](#)

|                     |                               |
|---------------------|-------------------------------|
| Version (or later)  | NDB 7.5.0                     |
| Type or units       | bytes                         |
| Default             | 4M                            |
| Range               | 32K - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)                 |

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of [TimeBetweenLocalCheckpoints](#).

#### Note

When [ODirect](#) is enabled, it is not necessary to set [DiskSyncSize](#); in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

- [MaxDiskWriteSpeed](#)

|                    |            |
|--------------------|------------|
| Version (or later) | NDB 7.5.0  |
| Type or units      | numeric    |
| Default            | 20M        |
| Range              | 1M - 1024G |

|              |               |
|--------------|---------------|
| Restart Type | S (NDB 7.5.0) |
|--------------|---------------|

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when no restarts (by this data node or any other data node) are taking place in this NDB Cluster.

For setting the maximum rate of disk writes allowed while this data node is restarting, use [MaxDiskWriteSpeedOwnRestart](#). For setting the maximum rate of disk writes allowed while other data nodes are restarting, use [MaxDiskWriteSpeedOtherNodeRestart](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MaxDiskWriteSpeedOtherNodeRestart](#)

|                     |               |
|---------------------|---------------|

| Default             | 50M           |
| Range               | 1M - 1024G    |
| <b>Restart Type</b> | S (NDB 7.5.0) |

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when one or more data nodes in this NDB Cluster are restarting, other than this node.

For setting the maximum rate of disk writes allowed while this data node is restarting, use [MaxDiskWriteSpeedOwnRestart](#). For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use [MaxDiskWriteSpeed](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MaxDiskWriteSpeedOwnRestart](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | numeric       |
| Default             | 200M          |
| Range               | 1M - 1024G    |
| <b>Restart Type</b> | S (NDB 7.5.0) |

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations while this data node is restarting.

For setting the maximum rate of disk writes allowed while other data nodes are restarting, use [MaxDiskWriteSpeedOtherNodeRestart](#). For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use [MaxDiskWriteSpeed](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MinDiskWriteSpeed](#)

|                    |            |
|--------------------|------------|
| Version (or later) | NDB 7.5.0  |
| Type or units      | numeric    |
| Default            | 10M        |
| Range              | 1M - 1024G |

|              |               |
|--------------|---------------|
| Restart Type | S (NDB 7.5.0) |
|--------------|---------------|

Set the minimum rate for writing to disk, in bytes per second, by local checkpoints and backup operations.

The maximum rates of disk writes allowed for LCPs and backups under various conditions are adjustable using the parameters `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOwnRestart`, and `MaxDiskWriteSpeedOtherNodeRestart`. See the descriptions of these parameters for more information.

- [ArbitrationTimeout](#)

|                    |                              |
|--------------------|------------------------------|
| Version (or later) | NDB 7.5.0                    |
| Type or units      | milliseconds                 |
| Default            | 7500                         |
| Range              | 10 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                |

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 7500 milliseconds (7.5 seconds).

- [Arbitration](#)

|                    |                                 |
|--------------------|---------------------------------|
| Version (or later) | NDB 7.5.0                       |
| Type or units      | enumeration                     |
| Default            | Default                         |
| Range              | Default, Disabled, WaitExternal |
| Restart Type       | N (NDB 7.5.0)                   |

The `Arbitration` parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the `ArbitrationRank` settings for the management and API nodes. This is the default value.
- **Disabled.** Setting `Arbitration = Disabled` in the `[ndbd default]` section of the `config.ini` file to accomplishes the same task as setting `ArbitrationRank` to 0 on all management and API nodes. When `Arbitration` is set in this way, any `ArbitrationRank` settings are ignored.
- **WaitExternal.** The `Arbitration` parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by `ArbitrationTimeout` has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting `Arbitration = WaitExternal` in the `[ndbd default]` section of the `config.ini` file. For best results with the `WaitExternal` setting, it is recommended that `ArbitrationTimeout` be 2 times as long as the interval required by the external cluster manager to perform arbitration.

#### Important

This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when `Arbitration` is set to different values for individual data nodes.

- [RestartSubscriberConnectTimeout](#)

|                     |                             |
|---------------------|-----------------------------|
| Version (or later)  | NDB 7.5.0                   |
| Type or units       | ms                          |
| Default             | 12000                       |
| Range               | 0 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)               |

This parameter determines the time that a data node waits for subscribing API nodes to connect. Once this timeout expires, any “missing” API nodes are disconnected from the cluster. To disable this timeout, set [RestartSubscriberConnectTimeout](#) to 0.

While this parameter is specified in milliseconds, the timeout itself is resolved to the next-greatest whole second.

**Buffering and logging.** Several [\[ndbd\]](#) configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the [NDB](#) storage engine’s file system abstraction layer.

- [UndoIndexBuffer](#)

|                     |                              |
|---------------------|------------------------------|
| Version (or later)  | NDB 7.5.0                    |
| Type or units       | unsigned                     |
| Default             | 2M                           |
| Range               | 1M - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)                |

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The [NDB](#) storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 ([Index UNDO buffers overloaded](#)).

#### Important

It is not safe to decrease the value of this parameter during a rolling restart.

- [UndoDataBuffer](#)

|                    |                              |
|--------------------|------------------------------|
| Version (or later) | NDB 7.5.0                    |
| Type or units      | unsigned                     |
| Default            | 16M                          |
| Range              | 1M - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                |

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 ([Data UNDO buffers overloaded](#)).

#### Important

It is not safe to decrease the value of this parameter during a rolling restart.

- [RedoBuffer](#)

|                    |                              |
|--------------------|------------------------------|
| Version (or later) | NDB 7.5.0                    |
| Type or units      | bytes                        |
| Default            | 32M                          |
| Range              | 1M - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                |

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

[RedoBuffer](#) sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 ([REDO log buffers overloaded](#)). For this reason, you should exercise care if you attempt to decrease the value of [RedoBuffer](#) as part of an online change in the cluster's configuration.

`ndbmttd` allocates a separate buffer for each LDM thread (see [ThreadConfig](#)). For example, with 4 LDM threads, an `ndbmttd` data node actually has 4 buffers and allocates [RedoBuffer](#) bytes to each one, for a total of `4 * RedoBuffer` bytes.

- [EventLogBufferSize](#)

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.5.0 |
|--------------------|-----------|

|                     |               |
|---------------------|---------------|
| Type or units       | bytes         |
| Default             | 8192          |
| Range               | 0 - 64K       |
| <b>Restart Type</b> | S (NDB 7.5.0) |

Controls the size of the circular buffer used for NDB log events within data nodes.

**Controlling log messages.** In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that there are no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- [LogLevelStartup](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | integer       |
| Default             | 1             |
| Range               | 0 - 15        |
| <b>Restart Type</b> | N (NDB 7.5.0) |

The reporting level for events generated during startup of the process.

The default level is 1.

- [LogLevelShutdown](#)

|                     |               |
|---------------------|---------------|

| Default             | 0             |
| Range               | 0 - 15        |
| <b>Restart Type</b> | N (NDB 7.5.0) |

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- [MemReportFrequency](#)

|                     |                             |
|---------------------|-----------------------------|
| Version (or later)  | NDB 7.5.0                   |
| Type or units       | unsigned                    |
| Default             | 0                           |
| Range               | 0 - 4294967039 (0xFFFFFFFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)               |

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the [DataMemory](#) and (NDB 7.5 and earlier) [IndexMemory](#), respectively, set in the [config.ini](#) file. For example, if [DataMemory](#) is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

[MemReportFrequency](#) is not a required parameter. If used, it can be set for all cluster data nodes in the [\[ndbd default\]](#) section of [config.ini](#), and can also be set or overridden for individual data nodes in the corresponding [\[ndbd\]](#) sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in [Section 21.5.3.2, “NDB Cluster Log Events”](#).

| Range        | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.5.0)               |

When a data node is started with the `--initial`, it initializes the redo log file during Start Phase 4 (see [Section 21.5.4, “Summary of NDB Cluster Start Phases”](#)). When very large values are set for `NoOfFragmentLogFile`, `FragmentLogFileSize`, or both, this initialization can take a long time. You can force reports on the progress of this process to be logged periodically, by means of the `StartupStatusReportFrequency` configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 1: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15557
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 2: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15570
```

These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

## Data Node Debugging Parameters

The following parameters are intended for use during testing or debugging of data nodes, and not for use in production.

- [DictTrace](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | bytes         |
| Default            | undefined     |
| Range              | 0 - 100       |
| Restart Type       | N (NDB 7.5.0) |

It is possible to cause logging of traces for events generated by creating and dropping tables using `DictTrace`. This parameter is useful only in debugging NDB kernel code. `DictTrace` takes an integer value. 0 (default - no logging) and 1 (logging enabled) are the only supported values prior to NDB 7.5.2. In NDB 7.5.2 and later, setting this parameter to 2 enables logging of additional `DBDICT` debugging output (Bug #20368450).

- [WatchdogImmediateKill](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.6.7     |
| Type or units      | boolean       |
| Default            | false         |
| Range              | true, false   |
| Added              | NDB 7.6.7     |
| Restart Type       | N (NDB 7.5.0) |

In NDB 7.6.7 and later, you can cause threads to be killed immediately whenever watchdog issues occur by enabling the `WatchdogImmediateKill` data node configuration parameter. This parameter should be used only when debugging or troubleshooting, to obtain trace files reporting exactly what was occurring the instant that execution ceased.

**Backup parameters.** The [\[ndbd\]](#) parameters discussed in this section define memory buffers set aside for execution of online backups.

- [BackupDataBufferSize](#)

|                              |                                |
|------------------------------|--------------------------------|
| Version (or later)           | NDB 7.5.0                      |
| Type or units                | bytes                          |
| Default                      | 16M                            |
| Range                        | 2M - 4294967039 (0xFFFFFEFF)   |
| Version (or later)           | NDB 7.5.1                      |
| Type or units                | bytes                          |
| Default                      | 16M                            |
| Range                        | 512K - 4294967039 (0xFFFFFEFF) |
| Deprecated                   | NDB 7.6.4                      |
| <a href="#">Restart Type</a> | N (NDB 7.5.0)                  |

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as [BackupWriteSize](#), the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB. The minimum was changed from 2M to 512K in NDB 7.5.1. (Bug #22749509)

- [BackupDiskWriteSpeedPct](#)

|                              |               |
|------------------------------|---------------|
| Version (or later)           | NDB 7.5.0     |
| Type or units                | percent       |
| Default                      | 50            |
| Range                        | 0 - 90        |
| <a href="#">Restart Type</a> | N (NDB 7.5.0) |

During normal operation, data nodes attempt to maximize the disk write speed used for local checkpoints and backups while remaining within the bounds set by [MinDiskWriteSpeed](#) and [MaxDiskWriteSpeed](#). Disk write throttling gives each LDM thread an equal share of the total budget. This allows parallel LCPs to take place without exceeding the disk I/O budget. Because a backup is executed by only one LDM thread, this effectively caused a budget cut, resulting in longer backup completion times, and—if the rate of change is sufficiently high—in failure to complete the backup when the backup log buffer fill rate is higher than the achievable write rate.

This problem can be addressed by using the [BackupDiskWriteSpeedPct](#) configuration parameter, which takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node's maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints. (This makes the disk write rate budget behave similarly to how it was handled in NDB Cluster 7.3 and earlier.)

The default value for this parameter is 50 (interpreted as 50%).

- [BackupLogBufferSize](#)

|                    |                              |
|--------------------|------------------------------|
| Version (or later) | NDB 7.5.0                    |
| Type or units      | bytes                        |
| Default            | 16M                          |
| Range              | 2M - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                |

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See [Section 21.5.8.3, “Configuration for NDB Cluster Backups”](#).

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- [BackupMemory](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | bytes                       |
| Default            | 32M                         |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Deprecated         | Yes (in NDB 7.4)            |
| Restart Type       | N (NDB 7.5.0)               |

This parameter is deprecated, and subject to removal in a future version of NDB Cluster. Any setting made for it is ignored.

- [BackupReportFrequency](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | seconds                     |
| Default            | 0                           |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see [Logging and checkpointing](#)). [BackupReportFrequency](#) represents the time in seconds between backup status reports.

The default value is 0.

- [BackupWriteSize](#)

|                     |                               |
|---------------------|-------------------------------|
| Version (or later)  | NDB 7.5.0                     |
| Type or units       | bytes                         |
| Default             | 256K                          |
| Range               | 32K - 4294967039 (0xFFFFFEFF) |
| Deprecated          | NDB 7.6.4                     |
| <b>Restart Type</b> | N (NDB 7.5.0)                 |

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 256KB.

- [BackupMaxWriteSize](#)

|                     |                                |
|---------------------|--------------------------------|
| Version (or later)  | NDB 7.5.0                      |
| Type or units       | bytes                          |
| Default             | 1M                             |
| Range               | 256K - 4294967039 (0xFFFFFEFF) |
| Deprecated          | NDB 7.6.4                      |
| <b>Restart Type</b> | N (NDB 7.5.0)                  |

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 1MB.

- [CompressedBackup](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | boolean       |
| Default             | false         |
| Range               | true, false   |
| <b>Restart Type</b> | N (NDB 7.5.0) |

Enabling this parameter causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

**Important**

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

**Note**

The location of the backup files is determined by the `BackupDataDir` data node configuration parameter.

**Additional requirements.** When specifying these parameters, the following relationships must hold true. Otherwise, the data node cannot start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

## NDB Cluster Realtime Performance Parameters

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

### Note

To make use of these parameters, the data node process must be run as system root.

- `BuildIndexThreads`

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | numeric       |
| Default            | 0             |
| Range              | 0 - 128       |
| Version (or later) | NDB 7.6.4     |
| Type or units      | numeric       |
| Default            | 128           |
| Range              | 0 - 128       |
| Restart Type       | N (NDB 7.5.0) |

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running `ndb_restore --rebuild-indexes`. It is supported only when there is more than one fragment for the table per data node (for example, when `COMMENT = "NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_LDM_X_2"` is used with `CREATE TABLE`).

Setting this parameter to 0 (the default) disables multithreaded building of ordered indexes.

This parameter is supported when using `ndbd` or `ndbmt`.

You can enable multithreaded builds during data node initial restarts by setting the `TwoPassInitialNodeRestartCopy` data node configuration parameter to `TRUE`.

- `LockExecuteThreadToCPU`

|                    |                |
|--------------------|----------------|
| Version (or later) | NDB 7.5.0      |
| Type or units      | set of CPU IDs |
| Default            | 0              |
| Range              | ...            |
| Restart Type       | N (NDB 7.5.0)  |

When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmt`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs

in any given order when using this parameter. You can obtain more finely-grained control of this type using [ThreadConfig](#).

[LockExecuteThreadToCPU](#) has no default value.

- [LockMaintThreadsToCPU](#)

|                              |               |
|------------------------------|---------------|
| Version (or later)           | NDB 7.5.0     |
| Type or units                | CPU ID        |
| Default                      | 0             |
| Range                        | 0 - 64K       |
| <a href="#">Restart Type</a> | N (NDB 7.5.0) |

This parameter specifies the ID of the CPU assigned to handle [NDBCLUSTER](#) maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). *There is no default value.*

- [Numa](#)

|                              |               |
|------------------------------|---------------|
| Version (or later)           | NDB 7.5.0     |
| Type or units                | numeric       |
| Default                      | 1             |
| Range                        | ...           |
| <a href="#">Restart Type</a> | N (NDB 7.5.0) |

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating system or by the data node process, whether the data node uses [ndbd](#) or [nbdmtd](#). By default, [NDB](#) attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting [Numa = 0](#) means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate [numactl](#) tool. That is, [Numa = 0](#) yields the system default behavior, which can be customised by [numactl](#). For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be problematic when using [nbdmtd](#); this is because [nbdmtd](#) allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting [Numa = 1](#) means that the data node process uses [libnuma](#) to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using [numactl](#).) Using interleaved allocation in effect tells the data node process to ignore non-uniform memory access but does not attempt to take any advantage of fast local memory; instead, the data node process tries to avoid imbalances due to slow remote memory. If interleaved allocation is not desired, set [Numa](#) to 0 so that the desired behavior can be determined on the operating system level.

The [Numa](#) configuration parameter is supported only on Linux systems where [libnuma.so](#) is available.

- [RealtimeScheduler](#)

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.5.0 |
| Type or units      | boolean   |
| Default            | false     |

|              |               |
|--------------|---------------|
| Range        | true, false   |
| Restart Type | N (NDB 7.5.0) |

Setting this parameter to 1 enables real-time scheduling of data node threads.

The default is 0 (scheduling disabled).

- [SchedulerExecutionTimer](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | µs            |
| Default            | 50            |
| Range              | 0 - 11000     |
| Restart Type       | N (NDB 7.5.0) |

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- [SchedulerResponsiveness](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | integer       |
| Default            | 5             |
| Range              | 0 - 10        |
| Restart Type       | N (NDB 7.5.0) |

Set the balance in the [NDB](#) scheduler between speed and throughput. This parameter takes an integer whose value is in the range 0-10 inclusive, with 5 as the default. Higher values provide better response times relative to throughput. Lower values provide increased throughput at the expense of longer response times.

- [SchedulerSpinTimer](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | µs            |
| Default            | 0             |
| Range              | 0 - 500       |
| Restart Type       | N (NDB 7.5.0) |

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

The default value is 0.

- [TwoPassInitialNodeRestartCopy](#)

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.5.0 |
| Type or units      | boolean   |
| Default            | false     |

|                     |               |
|---------------------|---------------|
| Range               | true, false   |
| Version (or later)  | NDB 7.6.4     |
| Type or units       | boolean       |
| Default             | true          |
| Range               | true, false   |
| <b>Restart Type</b> | N (NDB 7.5.0) |

Multithreaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `true`, which enables two-pass copying of data during initial node restarts. Beginning with NDB 7.6.4, this is the default value (Bug #26704312, Bug #27109117).

You must also set `BuildIndexThreads` to a nonzero value.

**Multi-Threading Configuration Parameters (`ndbmtd`).** `ndbmtd` runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the `config.ini` file. The first method is simply to set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter. A second method, makes it possible to set up more complex rules for `ndbmtd` multithreading using `ThreadConfig`. The next few paragraphs provide information about these parameters and their use with multithreaded data nodes.

- `MaxNoOfExecutionThreads`

|                     |                                 |
|---------------------|---------------------------------|
| Version (or later)  | NDB 7.5.0                       |
| Type or units       | integer                         |
| Default             | 2                               |
| Range               | 2 - 72                          |
| <b>Restart Type</b> | IS (NDB 7.5.0)<br>S (NDB 7.6.1) |

This parameter directly controls the number of execution threads used by `ndbmtd`, up to a maximum of 72. Although this parameter is set in `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmtd` and does not apply to `ndbd`.

Setting `MaxNoOfExecutionThreads` sets the number of threads for each type as determined by a matrix in the file `storage/ndb/src/kernel/vm/mt_thr_config.cpp`. This table shows these numbers of threads for possible values of `MaxNoOfExecutionThreads`.

**Table 21.11 MaxNoOfExecutionThreads values and the corresponding number of threads by thread type (LQH, TC, Send, Receive).**

| <code>MaxNoOfExecutionThreads</code> Value | LDM Threads | TC Threads | Send Threads | Receive Threads |
|--------------------------------------------|-------------|------------|--------------|-----------------|
| 0 .. 3                                     | 1           | 0          | 0            | 1               |
| 4 .. 6                                     | 2           | 0          | 0            | 1               |
| 7 .. 8                                     | 4           | 0          | 0            | 1               |
| 9                                          | 4           | 2          | 0            | 1               |

| 62                                   | 24                 | 19                | 8                   | 9                      |
| 63                                   | 24                 | 19                | 9                   | 9                      |
| 64                                   | 32                 | 16                | 7                   | 7                      |
| 65                                   | 32                 | 16                | 7                   | 8                      |
| 66                                   | 32                 | 17                | 7                   | 8                      |
| 67                                   | 32                 | 17                | 8                   | 8                      |
| 68                                   | 32                 | 18                | 8                   | 8                      |
| 69                                   | 32                 | 18                | 8                   | 9                      |
| 70                                   | 32                 | 19                | 8                   | 9                      |
| 71                                   | 32                 | 20                | 8                   | 9                      |
| 72                                   | 32                 | 20                | 8                   | 10                     |

There is always one SUMA (replication) thread.

`NoOfFragmentLogParts` should be set equal to the number of LDM threads used by `ndbmt`, as determined by the setting for this parameter. This ratio should not be any greater than 4:1; beginning with NDB 7.5.7 and NDB 7.6.3, a configuration in which this is the case is specifically disallowed. (Bug #25333414)

The number of LDM threads also determines the number of partitions used by an NDB table that is not explicitly partitioned; this is the number of LDM threads times the number of data nodes in the cluster. (If `ndbd` is used on the data nodes rather than `ndbmt`, then there is always a single LDM thread; in this case, the number of partitions created automatically is simply equal to the number of data nodes. See [Section 21.1.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#), for more information.

Adding large tablespaces for Disk Data tables when using more than the default number of LDM threads may cause issues with resource and CPU usage if the disk page buffer is insufficiently large; see the description of the `DiskPageBufferMemory` configuration parameter, for more information.

The thread types are described later in this section (see [ThreadConfig](#)).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error `Error line number: Illegal value value for parameter MaxNoOfExecutionThreads`.

For `MaxNoOfExecutionThreads`, a value of 0 or 1 is rounded up internally by NDB to 2, so that 2 is considered this parameter's default and minimum value.

`MaxNoOfExecutionThreads` is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not

assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use [ThreadConfig](#) instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

The multithreaded data node process always spawns, at a minimum, the threads listed here:

- 1 local query handler (LDM) thread
- 1 receive thread
- 1 subscription manager (SUMA or replication) thread

For a [MaxNoOfExecutionThreads](#) value of 8 or less, no TC threads are created, and TC handling is instead performed by the main thread.

Prior to NDB 7.6, changing the number of LDM threads always requires a system restart, whether it is changed using this parameter or [ThreadConfig](#). In NDB 7.6 and later it is possible to effect the change using a node initial restart (*N/I*) provided the following conditions are met:

- If, following the change, the number of LDM threads remains the same as before, nothing more than a simple node restart (rolling restart, or *N*) is required to implement the change.
- Otherwise (that is, if the number of LDM threads changes), it is still possible to effect the change using a node initial restart (*N/I*) provided the following two conditions are met:
  - a. Each LDM thread handles a maximum of 8 fragments, and
  - b. The total number of table fragments is an integer multiple of the number of LDM threads.

Prior to NDB 7.6, if the cluster's [IndexMemory](#) usage is greater than 50%, changing this requires an initial restart of the cluster. (A maximum of 30-35% [IndexMemory](#) usage is recommended in such cases.) Otherwise, resource usage and LDM thread allocation cannot be balanced between nodes, which can result in underutilized and overutilized LDM threads, and ultimately data node failures. In NDB 7.6 and later, an initial restart is *not* required to effect a change in this parameter.

- [NoOfFragmentLogParts](#)

|                    |                                 |
|--------------------|---------------------------------|
| Version (or later) | NDB 7.5.0                       |
| Type or units      | numeric                         |
| Default            | 4                               |
| Range              | 4, 6, 8, 10, 12, 16, 20, 24, 32 |
| Restart Type       | IN (NDB 7.5.0)                  |

Set the number of log file groups for redo logs belonging to this [ndbmtd](#). The value of this parameter should be set equal to the number of LDM threads used by [ndbmtd](#) as determined by the setting for [MaxNoOfExecutionThreads](#). Beginning with NDB 7.5.7 and NDB 7.6.3, a configuration using more than 4 redo log parts per LDM is disallowed. (Bug #25333414)

See the description of [MaxNoOfExecutionThreads](#) for more information.

- [ThreadConfig](#)

|                    |                |
|--------------------|----------------|

**S (NDB 7.6.1)**

This parameter is used with `ndbmtd` to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[,entry[,...]]

entry := type={param[,param[,...]]}

type := ldm | main | recv | send | rep | io | tc | watchdog | idxbld

param := count=number

| cpubind=cpu_list

| cpuset=cpu_list

| spintime=number

| realtime={0|1}

| nosend={0|1}

| thread_prio={0..10}

| cpubind_exclusive=cpu_list

| cpuset_exclusive=cpu_list
```

The curly braces (*{...}*) surrounding the list of parameters are required, even if there is only one parameter in the list.

A *param* (parameter) specifies any or all of the following information:

- The number of threads of the given type (*count*).
- The set of CPUs to which the threads of the given type are to be nonexclusively bound. This is determined by either one of `cpubind` or `cpuset`). `cpubind` causes each thread to be bound (nonexclusively) to a CPU in the set; `cpuset` means that each thread is bound (nonexclusively) to the set of CPUs specified.

On Solaris, you can instead specify a set of CPUs to which the threads of the given type are to be bound exclusively. `cpubind_exclusive` causes each thread to be bound exclusively to a CPU in the set; `cpuset_exclusive` means that each thread is bound exclusively to the set of CPUs specified.

Only one of `cpubind`, `cpuset`, `cpubind_exclusive`, or `cpuset_exclusive` can be provided in a single configuration.

- `spintime` determines the wait time in microseconds the thread spins before going to sleep.

The default value for `spintime` is the value of the `SchedulerSpinTimer` data node configuration parameter.

`spintime` does not apply to I/O threads, watchdog, or offline index build threads, and so cannot be set for these thread types.

- `realtime` can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that `thread_prio` cannot be set.

The `realtime` parameter is set by default to the value of the `RealtimeScheduler` data node configuration parameter.

`realtime` cannot be set for offline index build threads.

- By setting `nosend` to 1, you can prevent a `main`, `ldm`, `rep`, or `tc` thread from assisting the send threads. This parameter is 0 by default, and cannot be used with other types of threads.

`nosend` was added in NDB 7.6.4.

- `thread_prio` is a thread priority level that can be set from 0 to 10, with 10 representing the greatest priority. The default is 5. The precise effects of this parameter are platform-specific, and are described later in this section.

The thread priority level cannot be set for offline index build threads.

**thread\_prio settings and effects by platform.** The implementation of `thread_prio` differs between Linux/FreeBSD, Solaris, and Windows. In the following list, we discuss its effects on each of these platforms in turn:

- *Linux and FreeBSD*: We map `thread_prio` to a value to be supplied to the `nice` system call. Since a lower niceness value for a process indicates a higher process priority, increasing `thread_prio` has the effect of lowering the `nice` value.

**Table 21.12 Mapping of `thread_prio` to nice values on Linux and FreeBSD**

| <code>thread_prio</code> value | <code>nice</code> value |
|--------------------------------|-------------------------|
| 0                              | 19                      |
| 1                              | 16                      |
| 2                              | 12                      |
| 3                              | 8                       |
| 4                              | 4                       |
| 5                              | 0                       |
| 6                              | -4                      |
| 7                              | -8                      |
| 8                              | -12                     |
| 9                              | -16                     |
| 10                             | -20                     |

Some operating systems may provide for a maximum process niceness level of 20, but this is not supported by all targeted versions; for this reason, we choose 19 as the maximum `nice` value that can be set.

- *Solaris*: Setting `thread_prio` on Solaris sets the Solaris FX priority, with mappings as shown in the following table:

**Table 21.13 Mapping of `thread_prio` to FX priority on Solaris**

| <code>thread_prio</code> value | Solaris FX priority |
|--------------------------------|---------------------|
| 0                              | 15                  |
| 1                              | 20                  |
| 2                              | 25                  |
| 3                              | 30                  |
| 4                              | 35                  |
| 5                              | 40                  |
| 6                              | 45                  |
| 7                              | 50                  |
| 8                              | 55                  |
| 9                              | 59                  |

| <b>thread_prio</b> value | <b>Solaris FX priority</b> |
|--------------------------|----------------------------|
| 10                       | 60                         |

A `thread_prio` setting of 9 is mapped on Solaris to the special FX priority value 59, which means that the operating system also attempts to force the thread to run alone on its own CPU core.

- **Windows:** We map `thread_prio` to a Windows thread priority value passed to the Windows API `SetThreadPriority()` function. This mapping is shown in the following table:

**Table 21.14 Mapping of `thread_prio` to Windows thread priority**

| <b>thread_prio</b> value | <b>Windows thread priority</b>            |
|--------------------------|-------------------------------------------|
| 0 - 1                    | <code>THREAD_PRIORITY_LOWEST</code>       |
| 2 - 3                    | <code>THREAD_PRIORITY_BELOW_NORMAL</code> |
| 4 - 5                    | <code>THREAD_PRIORITY_NORMAL</code>       |
| 6 - 7                    | <code>THREAD_PRIORITY_ABOVE_NORMAL</code> |
| 8 - 10                   | <code>THREAD_PRIORITY_HIGHEST</code>      |

The `type` attribute represents an NDB thread type. The thread types supported, and the range of permitted `count` values for each, are provided in the following list:

- **ldm:** Local query handler (`DBLQH` kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes. Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. The value set for `ldm` must be one of the values 1, 2, 4, 6, 8, 12, 16, 24, or 32.

Changing the number of LDM threads normally requires an initial system restart to be effective and safe for cluster operations. This requirement is relaxed in NDB 7.6, as explained later in this section. (This is also true when this is done using `MaxNoOfExecutionThreads`.) *NDB 7.5 and earlier:* If `IndexMemory` usage is in excess of 50%, an initial restart of the cluster is required; a maximum of 30-35% `IndexMemory` usage is recommended in such cases. Otherwise, allocation of memory and LDM threads cannot be balanced between nodes, which can ultimately lead to data node failures.

Adding large tablespaces (hundreds of gigabytes or more) for Disk Data tables when using more than the default number of LDMs may cause issues with resource and CPU usage if `DiskPageBufferMemory` is not sufficiently large.

- **tc:** Transaction coordinator thread (`DBTC` kernel block) containing the state of an ongoing transaction. The maximum number of TC threads is 32.

Optimally, every new transaction can be assigned to a new TC thread. In most cases 1 TC thread per 2 LDM threads is sufficient to guarantee that this can happen. In cases where the number of writes is relatively small when compared to the number of reads, it is possible that only 1 TC thread per 4 LQH threads is required to maintain transaction states. Conversely, in applications that perform a great many updates, it may be necessary for the ratio of TC threads to LDM threads to approach 1 (for example, 3 TC threads to 4 LDM threads).

Setting `tc` to 0 causes TC handling to be done by the main thread. In most cases, this is effectively the same as setting it to 1.

Range: 0 - 32

- **main**: Data dictionary and transaction coordinator ([DBDIH](#) and [DBTC](#) kernel blocks), providing schema management. This is always handled by a single dedicated thread.

Range: 1 only.

- **recv**: Receive thread ([CMVMI](#) kernel block). Each receive thread handles one or more sockets for communicating with other nodes in an NDB Cluster, with one socket per node. NDB Cluster supports multiple receive threads; the maximum is 16 such threads.

Range: 1 - 16

- **send**: Send thread ([CMVMI](#) kernel block). To increase throughput, it is possible to perform sends from one or more separate, dedicated threads (maximum 8).

Previously, all threads handled their own sending directly; this can still be made to happen by setting the number of send threads to 0 (this also happens when [MaxNoOfExecutionThreads](#) is set less than 10). While doing so can have an adverse impact on throughput, it can also in some cases provide decreased latency.

Range: 0 - 16

- **rep**: Replication thread ([SUMA](#) kernel block). Asynchronous replication operations are always handled by a single, dedicated thread.

Range: 1 only.

- **io**: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

Range: 1 only.

- **watchdog**: Parameters settings associated with this type are actually applied to several threads, each having a specific use. These threads include the [SocketServer](#) thread, which receives connection setups from other nodes; the [SocketClient](#) thread, which attempts to set up connections to other nodes; and the thread watchdog thread that checks that threads are progressing.

Range: 1 only.

- **idxbld**: Offline index build threads. Unlike the other thread types listed previously, which are permanent, these are temporary threads which are created and used only during node or system

restarts, or when running `ndb_restore --rebuild-indexes`. They may be bound to CPU sets which overlap with CPU sets bound to permanent thread types.

`thread_prio`, `realtime`, and `spintime` values cannot be set for offline index build threads. In addition, `count` is ignored for this type of thread.

If `idxbld` is not specified, the default behavior is as follows:

- Offline index build threads are not bound if the I/O thread is also not bound, and these threads use any available cores.
- If the I/O thread is bound, then the offline index build threads are bound to the entire set of bound threads, due to the fact that there should be no other tasks for these threads to perform.

Range: 0 - 1.

This thread type was added in NDB 7.6.4. (Bug #25835748, Bug #26928111)

Prior to NDB 7.6, changing `ThreadConfig` requires a system initial restart. In NDB 7.6 and later, this requirement can be relaxed under certain circumstances:

- If, following the change, the number of LDM threads remains the same as before, nothing more than a simple node restart (rolling restart, or *N*) is required to implement the change.
- Otherwise (that is, if the number of LDM threads changes), it is still possible to effect the change using a node initial restart (*N*) provided the following two conditions are met:
  - a. Each LDM thread handles a maximum of 8 fragments, and
  - b. The total number of table fragments is an integer multiple of the number of LDM threads.

In any other case, a system initial restart is needed to change this parameter.

NDB 7.6.4 and later can distinguish between thread types by both of the following criteria:

- Whether the thread is an execution thread. Threads of type `main`, `ldm`, `recv`, `rep`, `tc`, and `send` are execution threads; `io`, `watchdog`, and `idxbld` threads are not considered execution threads.
- Whether the allocation of threads to a given task is permanent or temporary. Currently all thread types except `idxbld` are considered permanent; `idxbld` threads are regarded as temporary threads.

Simple examples:

```
Example 1.

ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}

Example 2.

Threadconfig=main={cpubind=0},ldm={count=4,cpubind=1,2,5,6},io={cpubind=3}
```

It is usually desirable when configuring thread usage for a data node host to reserve one or more number of CPUs for operating system and other tasks. Thus, for a host machine with 24 CPUs, you might want to use 20 CPU threads (leaving 4 for other uses), with 8 LDM threads, 4 TC threads (half the number of LDM threads), 3 send threads, 3 receive threads, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when `MaxNoOfExecutionThreads` is set equal to 20.) The following `ThreadConfig` setting performs these assignments, additionally binding all of these threads to specific CPUs:

```
ThreadConfig=ldm{count=8,cpubind=1,2,3,4,5,6,7,8},main={cpubind=9},io={cpubind=9}, \
rep={cpubind=10},tc{count=4,cpubind=11,12,13,14},recv={count=3,cpubind=15,16,17}, \
```

```
send{count=3,cpubind=18,19,20}
```

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

The following example incorporates groups of CPUs defined using both `cpuset` and `cpubind`, as well as use of thread prioritization.

```
ThreadConfig=ldm={count=4,cpuset=0-3,thread_prio=8,spintime=200}, \
ldm={count=4,cpubind=4-7,thread_prio=8,spintime=200}, \
tc={count=4,cpuset=8-9,thread_prio=6},send={count=2,thread_prio=10,cpubind=10-11}, \
main={count=1,cpubind=10},rep={count=1,cpubind=11}
```

In this case we create two LDM groups; the first uses `cpubind` and the second uses `cpuset`. `thread_prio` and `spintime` are set to the same values for each group. This means there are eight LDM threads in total. (You should ensure that `NoOfFragmentLogParts` is also set to 8.) The four TC threads use only two CPUs; it is possible when using `cpuset` to specify fewer CPUs than threads in the group. (This is not true for `cpubind`.) The send threads use two threads using `cpubind` to bind these threads to CPUs 10 and 11. The main and rep threads can reuse these CPUs.

This example shows how `ThreadConfig` and `NoOfFragmentLogParts` might be set up for a 24-CPU host with hyperthreading, leaving CPUs 10, 11, 22, and 23 available for operating system functions and interrupts:

```
NoOfFragmentLogParts=10
ThreadConfig=ldm={count=10,cpubind=0-4,12-16,thread_prio=9,spintime=200}, \
tc={count=4,cpuset=6-7,18-19,thread_prio=8},send={count=1,cpuset=8}, \
recv={count=1,cpuset=20},main={count=1,cpuset=9,21},rep={count=1,cpuset=9,21}, \
io={count=1,cpuset=9,21,thread_prio=8},watchdog={count=1,cpuset=9,21,thread_prio=9}
```

The next few examples include settings for `idxbld`. The first two of these demonstrate how a CPU set defined for `idxbld` can overlap those specified for other (permanent) thread types, the first using `cpuset` and the second using `cpubind`:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8},idxbld={cpuset=1-8}

ThreadConfig=main,ldm={count=1,cpubind=1},idxbld={count=1,cpubind=1}
```

The next example specifies a CPU for the I/O thread, but not for the index build threads:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8}
```

Since the `ThreadConfig` setting just shown locks threads to eight cores numbered 1 through 8, it is equivalent to the setting shown here:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8},idxbld={cpuset=1,2,3,4,5,6,7,8}
```

In order to take advantage of the enhanced stability that the use of `ThreadConfig` offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting `IRQBALANCE_BANNED_CPUS` in `/etc/sysconfig/irqbalance` to `0xFFFFF0`, and by using the `isolcpus` boot option in `grub.conf`. For specific information, see your operating system or platform documentation.

**Disk Data Configuration Parameters.** Configuration parameters affecting Disk Data behavior include the following:

- `DiskPageBufferEntries`

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | 32K pages     |
| Default             | 10            |
| Range               | 1 - 1000      |
| <b>Restart Type</b> | N (NDB 7.5.0) |

This is the number of page entries (page references) to allocate. It is specified as a number of 32K pages in [DiskPageBufferMemory](#). The default is sufficient for most cases but you may need to increase the value of this parameter if you encounter problems with very large transactions on Disk Data tables. Each page entry requires approximately 100 bytes.

- [DiskPageBufferMemory](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | bytes         |
| Default             | 64M           |
| Range               | 4M - 1T       |
| <b>Restart Type</b> | N (NDB 7.5.0) |

This determines the amount of space used for caching pages on disk, and is set in the [\[ndbd\]](#) or [\[ndbd default\]](#) section of the [config.ini](#) file. It is measured in bytes. Each page takes up 32 KB. This means that NDB Cluster Disk Data storage always uses  $N * 32$  KB memory where  $N$  is some nonnegative integer.

The default value for this parameter is [64M](#) (2000 pages of 32 KB each).

If the value for [DiskPageBufferMemory](#) is set too low in conjunction with using more than the default number of LDM threads in [ThreadConfig](#) (for example [{1dm=6...}](#)), problems can arise when trying to add a large (for example 500G) data file to a disk-based [NDB](#) table, wherein the process takes indefinitely long while occupying one of the CPU cores.

This is due to the fact that, as part of adding a data file to a tablespace, extent pages are locked into memory in an extra PGMAN worker thread, for quick metadata access. When adding a large file, this worker has insufficient memory for all of the data file metadata. In such cases, you should either increase [DiskPageBufferMemory](#), or add smaller tablespace files. You may also need to adjust [DiskPageBufferEntries](#).

You can query the [ndbinfo.diskpagebuffer](#) table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See [Section 21.5.14.20, “The ndbinfo diskpagebuffer Table”](#), for more information.

- [SharedGlobalMemory](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | bytes         |
| Default             | 128M          |
| Range               | 0 - 64T       |
| <b>Restart Type</b> | N (NDB 7.5.0) |

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, [UNDO](#) files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the [UNDO\\_BUFFER\\_SIZE](#) option used with [CREATE LOGFILE GROUP](#) and [ALTER](#)

`LOGFILE GROUP` statements, including any default value implied for this options by the setting of the `InitialLogFileGroup` data node configuration parameter. `SharedGlobalMemory` can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

The default value is `128M`.

- `DiskIOThreadPool`

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | threads                     |
| Default            | 2                           |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

This parameter determines the number of unbound threads used for Disk Data file access. Before `DiskIOThreadPool` was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With `DiskIOThreadPool`, you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can set `DiskIOThreadPool` higher to enable separate threads to handle the files on each disk.
- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for `DiskIOThreadPool`.

The default value for this parameter is 2.

- **Disk Data file system parameters.** The parameters in the following list make it possible to place NDB Cluster Disk Data files in specific directories without the need for using symbolic links.
  - `FileSystemPathDD`

|                    |                |
|--------------------|----------------|
| Version (or later) | NDB 7.5.0      |
| Type or units      | filename       |
| Default            | FileSystemPath |
| Range              | ...            |
| Restart Type       | IN (NDB 7.5.0) |

If this parameter is specified, then NDB Cluster Disk Data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE`

`GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDD` is not specified, then `FileSystemPath` is used.

If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathDataFiles`

|                    |                  |
|--------------------|------------------|
| Version (or later) | NDB 7.5.0        |
| Type or units      | filename         |
| Default            | FileSystemPathDD |
| Range              | ...              |
| Restart Type       | IN (NDB 7.5.0)   |

If this parameter is specified, then NDB Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathUndoFiles`

|                    |                  |
|--------------------|------------------|
| Version (or later) | NDB 7.5.0        |
| Type or units      | filename         |
| Default            | FileSystemPathDD |
| Range              | ...              |
| Restart Type       | IN (NDB 7.5.0)   |

If this parameter is specified, then NDB Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD UNDO` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see [Section 21.5.10.1, “NDB Cluster Disk Data Objects”](#).

- **Disk Data object creation parameters.** The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.
  - `InitialLogFileGroup`

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.5.0 |
| Type or units      | string    |

|              |                     |
|--------------|---------------------|
| Default      | [see documentation] |
| Range        | ...                 |
| Restart Type | S (NDB 7.5.0)       |

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. [InitialLogFileGroup](#) is specified as shown here:

```
InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list

file-specification-list:
 file-specification[; file-specification[; ...]]

file-specification:
 filename:size
```

The *name* of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size` is also optional; if omitted, it defaults to `64M`. Each *file-specification* corresponds to an undo log file, and at least one must be specified in the *file-specification-list*. Undo log files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
 ADD UNDOFILE 'undo1.log'
 INITIAL_SIZE 250M
 UNDO_BUFFER_SIZE 128M
 ENGINE NDBCCLUSTER;

ALTER LOGFILE GROUP LG1
 ADD UNDOFILE 'undo2.log'
 INITIAL_SIZE 150M
 ENGINE NDBCCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Resources for the initial log file group are added to the global memory pool along with those indicated by the value of [SharedGlobalMemory](#).

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of an NDB Cluster when different values are set on different data nodes is not defined.

- [InitialTablespace](#)

|                    |                     |
|--------------------|---------------------|
| Version (or later) | NDB 7.5.0           |
| Type or units      | string              |
| Default            | [see documentation] |
| Range              | ...                 |

|              |               |
|--------------|---------------|
| Restart Type | S (NDB 7.5.0) |
|--------------|---------------|

This parameter can be used to specify an NDB Cluster Disk Data tablespace that is created when performing an initial start of the cluster. [InitialTablespace](#) is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The *name* of the tablespace is optional and defaults to `DEFAULT-TS`. The *extent\_size* is also optional; it defaults to `1M`. The *file-specification-list* uses the same syntax as shown with the [InitialLogFileGroup](#) parameter, the only difference being that each *file-specification* used with [InitialTablespace](#) corresponds to a data file. At least one must be specified in the *file-specification-list*. Data files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathDataFiles`, just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying [InitialTablespace](#) in the `[ndbd default]` section of the `config.ini` file (as with [InitialLogFileGroup](#), this parameter should always be set in the `[ndbd default]` section, as the behavior of an NDB Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
 ADD DATAFILE 'data1.dat'
 EXTENT_SIZE 8M
 INITIAL_SIZE 2G
 ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
 ADD DATAFILE 'data2.dat'
 INITIAL_SIZE 4G
 ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating NDB Cluster Disk Data tables thereafter.

**Disk Data and GCP Stop errors.** Errors encountered when using Disk Data tables such as [Node nodeid killed this node because GCP stop was detected](#) (error 2303) are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of `TimeBetweenGlobalCheckpoints` tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for `DiskPageBufferMemory` as explained previously, it is also very important that the `DiskIOThreadPool` configuration parameter be set correctly; having `DiskIOThreadPool` set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the `TimeBetweenEpochsTimeout` data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.

**Parameters for configuring send buffer memory allocation.** Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed

while the node was running.) The `TotalSendBufferMemory` and `OverLoadLimit` data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of these parameters (as well as `SendBufferMemory`), see [Section 21.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#).

- `ExtraSendBufferMemory`

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

- `TotalSendBufferMemory`

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 21.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#).

See also [Section 21.5.7, “Adding NDB Cluster Data Nodes Online”](#).

**Redo log over-commit handling.** It is possible to control a data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by `DefaultOperationRedoProblemAction`. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- `RedoOverCommitCounter`

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | numeric                     |
| Default            | 3                           |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Version (or later) | NDB 7.5.17                  |
| Type or units      | numeric                     |
| Default            | 3                           |
| Range              | 1 - 4294967039 (0xFFFFFEFF) |
| Version (or later) | NDB 7.6.13                  |
| Type or units      | numeric                     |
| Default            | 3                           |
| Range              | 1 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

When `RedoOverCommitLimit` is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for `DefaultOperationRedoProblemAction` (by either queuing the operations to be re-tried, or aborting them).

- `RedoOverCommitLimit`

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.5.0 |
|--------------------|-----------|

|                     |                             |
|---------------------|-----------------------------|
| Type or units       | seconds                     |
| Default             | 20                          |
| Range               | 0 - 4294967039 (0xFFFFFEFF) |
| Version (or later)  | NDB 7.5.17                  |
| Type or units       | seconds                     |
| Default             | 20                          |
| Range               | 1 - 4294967039 (0xFFFFFEFF) |
| Version (or later)  | NDB 7.6.13                  |
| Type or units       | seconds                     |
| Default             | 20                          |
| Range               | 1 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)               |

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than [RedoOverCommitLimit](#), is kept and compared with [RedoOverCommitCounter](#), and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its [DefaultOperationRedoProblemAction](#) setting (it either queues the operations to be re-tried, or aborts them).

**Controlling restart attempts.** It is possible to exercise finely-grained control over restart attempts by data nodes when they fail to start using the [MaxStartFailRetries](#) and [StartFailRetryDelay](#) data node configuration parameters.

[MaxStartFailRetries](#) limits the total number of retries made before giving up on starting the data node, [StartFailRetryDelay](#) sets the number of seconds between retry attempts. These parameters are listed here:

- [StartFailRetryDelay](#)

|                     |                             |
|---------------------|-----------------------------|
| Version (or later)  | NDB 7.5.0                   |
| Type or units       | unsigned                    |
| Default             | 0                           |
| Range               | 0 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)               |

Use this parameter to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

Both this parameter and [MaxStartFailRetries](#) are ignored unless [StopOnError](#) is equal to 0.

- [MaxStartFailRetries](#)

|                     |                             |
|---------------------|-----------------------------|
| Version (or later)  | NDB 7.5.0                   |
| Type or units       | unsigned                    |
| Default             | 3                           |
| Range               | 0 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)               |

Use this parameter to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

Both this parameter and `StartFailRetryDelay` are ignored unless `StopOnError` is equal to 0.

**NDB index statistics parameters.** The parameters in the following list relate to NDB index statistics generation.

- [IndexStatAutoCreate](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | integer       |
| Default            | 0             |
| Range              | 0, 1          |
| Restart Type       | N (NDB 7.5.0) |

Enable (set equal to 1) or disable (set equal to 0) automatic statistics collection when indexes are created. Disabled by default.

- [IndexStatAutoUpdate](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | integer       |
| Default            | 0             |
| Range              | 0, 1          |
| Restart Type       | N (NDB 7.5.0) |

Enable (set equal to 1) or disable (set equal to 0) monitoring of indexes for changes and trigger automatic statistics updates these are detected. The amount and degree of change needed to trigger the updates are determined by the settings for the `IndexStatTriggerPct` and `IndexStatTriggerScale` options.

- [IndexStatSaveSize](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | bytes                       |
| Default            | 32768                       |
| Range              | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type       | IN (NDB 7.5.0)              |

Maximum space in bytes allowed for the saved statistics of any given index in the NDB system tables and in the `mysqld` memory cache. In NDB 7.5 and earlier, this consumes `IndexMemory`.

At least one sample is always produced, regardless of any size limit. This size is scaled by `IndexStatSaveScale`.

The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- [IndexStatSaveScale](#)

|                    |            |
|--------------------|------------|
| Version (or later) | NDB 7.5.0  |
| Type or units      | percentage |

|                     |                             |
|---------------------|-----------------------------|
| Default             | 100                         |
| Range               | 0 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | IN (NDB 7.5.0)              |

The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- `IndexStatTriggerPct`

|                     |                             |
|---------------------|-----------------------------|
| Version (or later)  | NDB 7.5.0                   |
| Type or units       | percentage                  |
| Default             | 100                         |
| Range               | 0 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | IN (NDB 7.5.0)              |

Percentage change in updates that triggers an index statistics update. The value is scaled by `IndexStatTriggerScale`. You can disable this trigger altogether by setting `IndexStatTriggerPct` to 0.

- `IndexStatTriggerScale`

|                     |                             |
|---------------------|-----------------------------|
| Version (or later)  | NDB 7.5.0                   |
| Type or units       | percentage                  |
| Default             | 100                         |
| Range               | 0 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | IN (NDB 7.5.0)              |

Scale `IndexStatTriggerPct` by this amount times 0.01 for a large index. A value of 0 disables scaling.

- `IndexStatUpdateDelay`

|                     |                             |
|---------------------|-----------------------------|
| Version (or later)  | NDB 7.5.0                   |
| Type or units       | seconds                     |
| Default             | 60                          |
| Range               | 0 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | IN (NDB 7.5.0)              |

Minimum delay in seconds between automatic index statistics updates for a given index. Setting this variable to 0 disables any delay. The default is 60 seconds.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 21.15 NDB Cluster restart types**

| Symbol | Restart Type | Description                                                                                                                                  |
|--------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| N      | Node         | The parameter can be updated using a rolling restart (see <a href="#">Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”</a> ) |
| S      | System       | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter                                         |

| Symbol | Restart Type | Description                                                          |
|--------|--------------|----------------------------------------------------------------------|
| I      | Initial      | Data nodes must be restarted using the <code>--initial</code> option |

### 21.3.3.7 Defining SQL and Other API Nodes in an NDB Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

#### Note

For a discussion of MySQL server options for NDB Cluster, see [MySQL Server Options for NDB Cluster](#). For information about MySQL server system variables relating to NDB Cluster, see [NDB Cluster System Variables](#).

- `Id`

|                    |                |
|--------------------|----------------|
| Version (or later) | NDB 7.5.0      |
| Type or units      | unsigned       |
| Default            | [...]          |
| Range              | 1 - 255        |
| Restart Type       | IS (NDB 7.5.0) |

The `Id` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

#### Note

Data node IDs must be less than 49, regardless of the NDB Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying API nodes. (`Id` continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

- `ConnectionMap`

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | string        |
| Default            | [...]         |
| Range              | ...           |
| Restart Type       | N (NDB 7.5.0) |

Specifies which data nodes to connect.

- `NodeId`

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.5.0 |
|--------------------|-----------|

|                     |                |
|---------------------|----------------|
| Type or units       | unsigned       |
| Default             | [...]          |
| Range               | 1 - 255        |
| <b>Restart Type</b> | IS (NDB 7.5.0) |

The `NodeId` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

#### Note

Data node IDs must be less than 49, regardless of the NDB Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes. An alias, `Id`, was used for this purpose in very old versions of NDB Cluster, and continues to be supported for backward compatibility; it is now deprecated and generates a warning when used, and is subject to removal in a future release of NDB Cluster.

- `ExecuteOnComputer`

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | name          |
| Default             | [...]         |
| Range               | ...           |
| Deprecated          | NDB 7.5.0     |
| <b>Restart Type</b> | S (NDB 7.5.0) |

This refers to the `Id` set for one of the computers (hosts) defined in a `[computer]` section of the configuration file.

#### Important

This parameter is deprecated as of NDB 7.5.0, and is subject to removal in a future release. Use the `HostName` parameter instead.

- `HostName`

|                     |                    |
|---------------------|--------------------|
| Version (or later)  | NDB 7.5.0          |
| Type or units       | name or IP address |
| Default             | [...]              |
| Range               | ...                |
| <b>Restart Type</b> | N (NDB 7.5.0)      |

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or `ExecuteOnComputer` is required.

If no `HostName` or `ExecuteOnComputer` is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding "slot" from any host which can establish a network connection to the management server host machine. *This differs from the default behavior for data nodes, where `localhost` is assumed for `HostName` unless otherwise specified.*

- [LocationDomainId](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.6.4     |
| Type or units       | integer       |
| Default             | 0             |
| Range               | 0 - 16        |
| Added               | NDB 7.6.4     |
| <b>Restart Type</b> | S (NDB 7.5.0) |

Assigns an SQL or other API node to a specific [availability domain](#) (also known as an availability zone) within a cloud. By informing [NDB](#) which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use [NDB](#) transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

[LocationDomainId](#) takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- [ArbitrationRank](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | 0-2           |
| Default             | 0             |
| Range               | 0 - 2         |
| <b>Restart Type</b> | N (NDB 7.5.0) |

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its [ArbitrationRank](#) to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

By setting [ArbitrationRank](#) to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the [Arbitration](#) parameter in the [\[ndbd default\]](#) section of the [config.ini](#) global configuration file.

- [ArbitrationDelay](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | milliseconds                |
| Default            | 0                           |
| Range              | 0 - 4294967039 (0xFFFFFFFF) |

|              |               |
|--------------|---------------|
| Restart Type | N (NDB 7.5.0) |
|--------------|---------------|

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests are delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- [BatchByteSize](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | bytes         |
| Default            | 16K           |
| Range              | 1K - 1M       |
| Restart Type       | N (NDB 7.5.0) |

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records ([BatchSize](#)) and in terms of bytes ([BatchByteSize](#)). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value is 16K.

- [BatchSize](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | records       |
| Default            | 256           |
| Range              | 1 - 992       |
| Restart Type       | N (NDB 7.5.0) |

This parameter is measured in number of records and is by default set to 256. The maximum size is 992.

- [ExtraSendBufferMemory](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | bytes                       |
| Default            | 0                           |
| Range              | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type       | N (NDB 7.5.0)               |

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using [TotalSendBufferMemory](#), [SendBufferMemory](#), or both.

- [HeartbeatThreadPriority](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | string        |
| Default            | [...]         |
| Range              | ...           |
| Restart Type       | N (NDB 7.5.0) |

Use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes. The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
 {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of **FIFO** (first in, first in) or **RR** (round robin). This followed optionally by the priority (an integer).

- [MaxScanBatchSize](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | bytes         |
| Default            | 256K          |
| Range              | 32K - 16M     |
| Restart Type       | N (NDB 7.5.0) |

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- [TotalSendBufferMemory](#)

|                    |                                |
|--------------------|--------------------------------|
| Version (or later) | NDB 7.5.0                      |
| Type or units      | bytes                          |
| Default            | 0                              |
| Range              | 256K - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                  |

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 21.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#).

- [AutoReconnect](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | boolean       |
| Default            | false         |
| Range              | true, false   |
| Restart Type       | N (NDB 7.5.0) |

This parameter is **false** by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an

existing one, as re-use of connections can cause problems when using dynamically-allocated node IDs. (Bug #45921)

**Note**

This parameter can be overridden using the NDB API. For more information, see [Ndb\\_cluster\\_connection::set\\_auto\\_reconnect\(\)](#), and [Ndb\\_cluster\\_connection::get\\_auto\\_reconnect\(\)](#).

- [DefaultOperationRedoProblemAction](#)

|                              |               |
|------------------------------|---------------|
| Version (or later)           | NDB 7.5.0     |
| Type or units                | enumeration   |
| Default                      | QUEUE         |
| Range                        | ABORT, QUEUE  |
| <a href="#">Restart Type</a> | N (NDB 7.5.0) |

This parameter (along with [RedoOverCommitLimit](#) and [RedoOverCommitCounter](#)) controls the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than [RedoOverCommitLimit](#) seconds, more than [RedoOverCommitCounter](#) times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of [DefaultOperationRedoProblemAction](#), listed here:

- [ABORT](#): Any pending operations from aborted transactions are also aborted.
- [QUEUE](#): Pending operations from transactions that were aborted are queued up to be re-tried. This is the default. Pending operations are still aborted when the redo log runs out of space—that is, when [P\\_TAIL\\_PROBLEM](#) errors occur.
- [DefaultHashMapSize](#)

|                              |               |
|------------------------------|---------------|
| Version (or later)           | NDB 7.5.0     |
| Type or units                | buckets       |
| Default                      | 3840          |
| Range                        | 0 - 3840      |
| <a href="#">Restart Type</a> | N (NDB 7.5.0) |

The size of the table hash maps used by NDB is configurable using this parameter. [DefaultHashMapSize](#) can take any of three possible values (0, 240, 3840).

The original intended use for this parameter was to facilitate upgrades and especially downgrades to and from very old releases with differing default hash map sizes. This is not an issue when upgrading from NDB Cluster 7.3 (or later) to later versions.

Decreasing this parameter online after any tables have been created or modified with [DefaultHashMapSize](#) equal to 3840 is not currently supported.

- [Wan](#)

|                    |             |
|--------------------|-------------|
| Version (or later) | NDB 7.5.0   |
| Type or units      | boolean     |
| Default            | false       |
| Range              | true, false |

|              |               |
|--------------|---------------|
| Restart Type | N (NDB 7.5.0) |
|--------------|---------------|

Use WAN TCP setting as default.

- [ConnectBackoffMaxTime](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | integer                     |
| Default            | 0                           |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the [StartConnectBackoffMaxTime](#) parameter is applied; otherwise, [ConnectBackoffMaxTime](#) is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches [ConnectBackoffMaxTime](#) milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up [HeartbeatIntervalDbApi](#) for the API node to be notified that this has occurred.

- [StartConnectBackoffMaxTime](#)

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | integer                     |
| Default            | 0                           |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)               |

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the [StartConnectBackoffMaxTime](#) parameter is applied; otherwise, [ConnectBackoffMaxTime](#) is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches [StartConnectBackoffMaxTime](#) milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up [HeartbeatIntervalDbApi](#) for the API node to be notified that this has occurred.

**API Node Debugging Parameters.** Beginning with NDB 7.5.2, you can use the `ApiVerbose` configuration parameter to enable debugging output from a given API node. This parameter takes an integer value. 0 is the default, and disables such debugging; 1 enables debugging output to the cluster log; 2 adds `DBDICT` debugging output as well. (Bug #20638450) See also [DUMP 1229](#).

You can also obtain information from a MySQL server running as an NDB Cluster SQL node using `SHOW STATUS` in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 5 |
| Ndb_config_from_host | 198.51.100.112 |
| Ndb_config_from_port | 1186 |
| Ndb_number_of_storage_nodes | 4 |
+-----+-----+
4 rows in set (0.02 sec)
```

For information about the status variables appearing in the output from this statement, see [NDB Cluster Status Variables](#).

#### Note

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 21.16 NDB Cluster restart types**

| Symbol | Restart Type | Description                                                                                                                                  |
|--------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| N      | Node         | The parameter can be updated using a rolling restart (see <a href="#">Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”</a> ) |
| S      | System       | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter                                         |
| I      | Initial      | Data nodes must be restarted using the <code>--initial</code> option                                                                         |

### 21.3.3.8 Defining the System

The `[system]` section is used for parameters applying to the cluster as a whole. The `Name` system parameter is used with MySQL Enterprise Monitor; `ConfigGenerationNumber` and `PrimaryMGMNNode` are not used in production environments. Except when using NDB Cluster with MySQL Enterprise Monitor, is not necessary to have a `[system]` section in the `config.ini` file.

More information about these parameters can be found in the following list:

- `ConfigGenerationNumber`

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.5.0 |
| Type or units      | unsigned  |

|                     |                             |
|---------------------|-----------------------------|
| Default             | 0                           |
| Range               | 0 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)               |

Configuration generation number. This parameter is currently unused.

- [Name](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | string        |
| Default             | [...]         |
| Range               | ...           |
| <b>Restart Type</b> | N (NDB 7.5.0) |

Set a name for the cluster. This parameter is required for deployments with MySQL Enterprise Monitor; it is otherwise unused.

You can obtain the value of this parameter by checking the [Ndb\\_system\\_name](#) status variable. In NDB API applications, you can also retrieve it using [get\\_system\\_name\(\)](#).

- [PrimaryMGMNode](#)

|                     |                             |
|---------------------|-----------------------------|
| Version (or later)  | NDB 7.5.0                   |
| Type or units       | unsigned                    |
| Default             | 0                           |
| Range               | 0 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)               |

Node ID of the primary management node. This parameter is currently unused.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 21.17 NDB Cluster restart types**

| Symbol | Restart Type | Description                                                                                                                                  |
|--------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| N      | Node         | The parameter can be updated using a rolling restart (see <a href="#">Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”</a> ) |
| S      | System       | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter                                         |
| I      | Initial      | Data nodes must be restarted using the <a href="#">--initial</a> option                                                                      |

### 21.3.3.9 MySQL Server Options and Variables for NDB Cluster

This section provides information about MySQL server options, server and status variables that are specific to NDB Cluster. For general information on using these, and for other options and variables not specific to NDB Cluster, see [Section 5.1, “The MySQL Server”](#).

For NDB Cluster configuration parameters used in the cluster configuration file (usually named [config.ini](#)), see [Section 21.3, “Configuration of NDB Cluster”](#).

## MySQL Server Options for NDB Cluster

This section provides descriptions of `mysqld` server options relating to NDB Cluster. For information about `mysqld` options not specific to NDB Cluster, and for general information about the use of options with `mysqld`, see [Section 5.1.6, “Server Command Options”](#).

For information about command-line options used with other NDB Cluster processes, see [Section 21.4, “NDB Cluster Programs”](#).

- `--ndbcluster`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--ndbcluster[=value]</code> |
| Disabled by         | <code>skip-ndbcluster</code>      |
| Type                | Boolean                           |
| Default Value       | <code>OFF</code>                  |

The `NDBCLUSTER` storage engine is necessary for using NDB Cluster. If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

It is not necessary or desirable to use this option together with `--initialize`. Beginning with NDB 7.5.4, `--ndbcluster` is ignored (and the `NDB` storage engine is *not* enabled) if `--initialize` is also used. (Bug #81689, Bug #23518923)

- `--ndb-allow-copying-alter-table=[ON|OFF]`

|                     |                                                         |
|---------------------|---------------------------------------------------------|
| Command-Line Format | <code>--ndb-allow-copying-alter-table[={OFF ON}]</code> |
| Introduced          | 5.7.10-ndb-7.5.0                                        |
| System Variable     | <code>ndb_allow_copying_alter_table</code>              |
| Scope               | Global, Session                                         |
| Dynamic             | Yes                                                     |
| Type                | Boolean                                                 |
| Default Value       | <code>ON</code>                                         |

Let `ALTER TABLE` and other DDL statements use copying operations on `NDB` tables. Set to `OFF` to keep this from happening; doing so may improve performance of critical applications.

- `--ndb-batch-size=`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--ndb-batch-size</code> |
| System Variable     | <code>ndb_batch_size</code>   |
| Scope               | Global                        |
| Dynamic             | No                            |
| Type                | Integer                       |
| Default Value       | <code>32768</code>            |
| Minimum Value       | <code>0</code>                |
| Maximum Value       | <code>31536000</code>         |

This sets the size in bytes that is used for NDB transaction batches.

- `--ndb-cluster-connection-pool=`

|                     |                                            |
|---------------------|--------------------------------------------|
| Command-Line Format | <code>--ndb-cluster-connection-pool</code> |
| System Variable     | <code>ndb_cluster_connection_pool</code>   |

|                 |                                          |
|-----------------|------------------------------------------|
| System Variable | <code>ndb_cluster_connection_pool</code> |
| Scope           | Global                                   |
| Scope           | Global                                   |
| Dynamic         | No                                       |
| Dynamic         | No                                       |
| Type            | Integer                                  |
| Default Value   | 1                                        |
| Minimum Value   | 1                                        |
| Maximum Value   | 63                                       |

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own `[api]` or `[mysqld]` section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

### Important

Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must *not* use a node ID as part of the cluster connection string when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connection string when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

- `--ndb-cluster-connection-pool-nodeids=list`

|                                            |                                                    |
|--------------------------------------------|----------------------------------------------------|
| Command-Line Format                        | <code>--ndb-cluster-connection-pool-nodeids</code> |
| Introduced                                 | 5.7.10-ndb-7.5.0                                   |
| System Variable ( $\geq$ 5.7.10-ndb-7.5.0) | <code>ndb_cluster_connection_pool_nodeids</code>   |
| Scope ( $\geq$ 5.7.10-ndb-7.5.0)           | Global                                             |
| Dynamic ( $\geq$ 5.7.10-ndb-7.5.0)         | No                                                 |
| Type                                       | Set                                                |
| Default Value                              |                                                    |

Specifies a comma-separated list of node IDs for connections to the cluster used by an SQL node. The number of nodes in this list must be the same as the value set for the `--ndb-cluster-connection-pool` option.

`--ndb-cluster-connection-pool-nodeids` was added in NDB 7.5.0.

- `--ndb-blob-read-batch-bytes=bytes`

|                     |                                          |
|---------------------|------------------------------------------|
| Command-Line Format | <code>--ndb-blob-read-batch-bytes</code> |
| System Variable     | <code>ndb_blob_read_batch_bytes</code>   |
| Scope               | Global, Session                          |
| Dynamic             | Yes                                      |
| Type                | Integer                                  |
| Default Value       | 65536                                    |
| Minimum Value       | 0                                        |
| Maximum Value       | 4294967295                               |

This option can be used to set the size (in bytes) for batching of `BLOB` data reads in NDB Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be read within the current transaction, any pending `BLOB` read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling `BLOB` read batching.

#### Note

In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobReadBytes()` and `getMaxPendingBlobReadBytes()` methods.

- `--ndb-blob-write-batch-bytes=bytes`

|                     |                                           |
|---------------------|-------------------------------------------|
| Command-Line Format | <code>--ndb-blob-write-batch-bytes</code> |
| System Variable     | <code>ndb_blob_write_batch_bytes</code>   |
| Scope               | Global, Session                           |
| Dynamic             | Yes                                       |
| Type                | Integer                                   |
| Default Value       | 65536                                     |
| Minimum Value       | 0                                         |
| Maximum Value       | 4294967295                                |

This option can be used to set the size (in bytes) for batching of `BLOB` data writes in NDB Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be written within the current transaction, any pending `BLOB` write operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling `BLOB` write batching.

#### Note

In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobWriteBytes()` and `getMaxPendingBlobWriteBytes()` methods.

- `--ndb-connectstring=connection_string`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--ndb-connectstring</code> |
|---------------------|----------------------------------|

|      |        |
|------|--------|
| Type | String |
|------|--------|

When using the `NDBCLUSTER` storage engine, this option specifies the management server that distributes cluster configuration data. See [Section 21.3.3.3, “NDB Cluster Connection Strings”](#), for syntax.

- `--ndb-default-column-format=[FIXED|DYNAMIC]`

|                                                        |                                                          |
|--------------------------------------------------------|----------------------------------------------------------|
| Command-Line Format                                    | <code>--ndb-default-column-format={FIXED DYNAMIC}</code> |
| Introduced                                             | 5.7.11-ndb-7.5.1                                         |
| System Variable                                        | <code>ndb_default_column_format</code>                   |
| Scope                                                  | Global                                                   |
| Dynamic                                                | Yes                                                      |
| Type                                                   | Enumeration                                              |
| Default Value (≥ 5.7.16-ndb-7.5.4)                     | <code>FIXED</code>                                       |
| Default Value (≥ 5.7.11-ndb-7.5.1, ≤ 5.7.13-ndb-7.5.3) | <code>DYNAMIC</code>                                     |
| Valid Values                                           | <code>FIXED</code><br><code>DYNAMIC</code>               |

In NDB 7.5.1 and later, sets the default `COLUMN_FORMAT` and `ROW_FORMAT` for new tables (see [Section 13.1.18, “CREATE TABLE Statement”](#)).

In NDB 7.5.1, the default for this option was `DYNAMIC`; in NDB 7.5.4, the default was changed to `FIXED` to maintain backwards compatibility with older release series (Bug #24487363).

- `--ndb-deferred-constraints=[0|1]`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--ndb-deferred-constraints</code> |
| System Variable     | <code>ndb_deferred_constraints</code>   |
| Scope               | Global, Session                         |
| Dynamic             | Yes                                     |
| Type                | Integer                                 |
| Default Value       | <code>0</code>                          |
| Minimum Value       | <code>0</code>                          |
| Maximum Value       | <code>1</code>                          |

Controls whether or not constraint checks on unique indexes are deferred until commit time, where such checks are supported. `0` is the default.

This option is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- `--ndb-distribution=[KEYHASH|LINHASH]`

|                     |                                                   |
|---------------------|---------------------------------------------------|
| Command-Line Format | <code>--ndb-distribution={KEYHASH LINHASH}</code> |
| System Variable     | <code>ndb_distribution</code>                     |
| Scope               | Global                                            |
| Dynamic             | Yes                                               |

|               |                    |
|---------------|--------------------|
| Type          | Enumeration        |
| Default Value | KEYHASH            |
| Valid Values  | LINHASH<br>KEYHASH |
|               |                    |

Controls the default distribution method for NDB tables. Can be set to either of KEYHASH (key hashing) or LINHASH (linear hashing). KEYHASH is the default.

- `--ndb-log-apply-status`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-log-apply-status[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_apply_status</code>              |
| Scope               | Global                                         |
| Dynamic             | No                                             |
| Type                | Boolean                                        |
| Default Value       | OFF                                            |

Causes a replica `mysqld` to log any updates received from its immediate source to the `mysql.ndb_apply_status` table in its own binary log using its own server ID rather than the server ID of the source. In a circular or chain replication setting, this allows such updates to propagate to the `mysql.ndb_apply_status` tables of any MySQL servers configured as replicas of the current `mysqld`.

In a chain replication setup, using this option allows downstream (replica) clusters to be aware of their positions relative to all of their upstream contributors (sources).

In a circular replication setup, this option causes changes to `ndb_apply_status` tables to complete the entire circuit, eventually propagating back to the originating NDB Cluster. This also allows a cluster acting as a source to see when its changes (epochs) have been applied to the other clusters in the circle.

This option has no effect unless the MySQL server is started with the `--ndbcluster` option.

- `--ndb-log-empty-epochs=[ON|OFF]`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-log-empty-epochs[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_empty_epochs</code>              |
| Scope               | Global                                         |
| Dynamic             | Yes                                            |
| Type                | Boolean                                        |
| Default Value       | OFF                                            |

Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_slave_updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

Because `--ndb-log-empty-epochs=1` causes the size of the `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

- `--ndb-log-empty-update=[ON|OFF]`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-log-empty-update[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_empty_update</code>              |
| Scope               | Global                                         |
| Dynamic             | Yes                                            |
| Type                | Boolean                                        |
| Default Value       | OFF                                            |

Causes updates that produced no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, when `log_slave_updates` is enabled.

By default this option is disabled (OFF). Disabling `--ndb-log-empty-update` causes updates with no changes not to be written to the binary log.

- `--ndb-log-exclusive-reads=[0|1]`

|                     |                                                   |
|---------------------|---------------------------------------------------|
| Command-Line Format | <code>--ndb-log-exclusive-reads[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_exclusive_reads</code>              |
| Scope               | Global, Session                                   |
| Dynamic             | Yes                                               |
| Type                | Boolean                                           |
| Default Value       | 0                                                 |

Starting the server with this option causes primary key reads to be logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. You can also enable and disable these locks at runtime by setting the value of the `ndb_log_exclusive_reads` system variable to 1 or 0, respectively. 0 (disable locking) is the default.

For more information, see [Read conflict detection and resolution](#).

- `--ndb-log-fail-terminate`

|                     |                                       |
|---------------------|---------------------------------------|
| Command-Line Format | <code>--ndb-log-fail-terminate</code> |
| Introduced          | 5.7.29-ndb-7.6.14                     |
| System Variable     | <code>ndb_log_fail_terminate</code>   |
| Scope               | Global                                |
| Dynamic             | No                                    |
| Type                | Boolean                               |
| Default Value       | FALSE                                 |

When this option is specified, and complete logging of all found row events is not possible, the `mysqld` process is terminated.

- `--ndb-log-orig`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--ndb-log-orig[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_orig</code>              |
| Scope               | Global                                 |
| Dynamic             | No                                     |
| Type                | Boolean                                |

|               |                  |
|---------------|------------------|
| Default Value | <code>OFF</code> |
|---------------|------------------|

Log the originating server ID and epoch in the `ndb_binlog_index` table.

#### Note

This makes it possible for a given epoch to have multiple rows in `ndb_binlog_index`, one for each originating epoch.

For more information, see [Section 21.6.4, “NDB Cluster Replication Schema and Tables”](#).

- `--ndb-log-transaction-id`

|                     |                                                  |
|---------------------|--------------------------------------------------|
| Command-Line Format | <code>--ndb-log-transaction-id[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_transaction_id</code>              |
| Scope               | Global                                           |
| Dynamic             | No                                               |
| Type                | Boolean                                          |
| Default Value       | <code>OFF</code>                                 |

Causes a replica `mysqld` to write the NDB transaction ID in each row of the binary log. Such logging requires the use of the Version 2 event format for the binary log; thus, the `log_bin_use_v1_row_events` system variable must be disabled to use this option.

This option is not supported in mainline MySQL Server 5.7. It is required to enable NDB Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function (see [NDB\\$EPOCH\\_TRANS\(\)](#)).

The default value is `FALSE`.

For more information, see [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `--ndb-log-update-as-write`

|                     |                                                   |
|---------------------|---------------------------------------------------|
| Command-Line Format | <code>--ndb-log-update-as-write[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_update_as_write</code>              |
| Scope               | Global                                            |
| Dynamic             | Yes                                               |
| Type                | Boolean                                           |
| Default Value       | <code>ON</code>                                   |

Whether updates on the source are written to the binary log as updates (`OFF`) or writes (`ON`). Used in NDB Replication conflict resolution; for more information, see [Logging Changed Data as Updates](#).

- `--ndb-log-updated-only`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-log-updated-only[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_updated_only</code>              |
| Scope               | Global                                         |
| Dynamic             | Yes                                            |
| Type                | Boolean                                        |

|               |                 |
|---------------|-----------------|
| Default Value | <code>ON</code> |
|---------------|-----------------|

Whether `mysqld` writes complete rows (`ON`) or updates only (`OFF`) to the binary log. Used in NDB Replication conflict resolution; see [Logging Full or Partial Rows](#), for more information.

- `--ndb-log-update-minimal`

|                     |                                                  |
|---------------------|--------------------------------------------------|
| Command-Line Format | <code>--ndb-log-update-minimal[={OFF ON}]</code> |
| Introduced          | 5.7.18-ndb-7.6.3                                 |
| System Variable     | <code>ndb_log_update_minimal</code>              |
| Scope               | Global                                           |
| Dynamic             | Yes                                              |
| Type                | Boolean                                          |
| Default Value       | <code>OFF</code>                                 |

Log updates in a minimal fashion, by writing only the primary key values in the before image, and only the changed columns in the after image. This may cause compatibility problems if replicating to storage engines other than [NDB](#).

- `--ndb-mgmd-host=host[:port]`

|                     |                                                   |
|---------------------|---------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=host_name[:port_num]</code> |
| Type                | String                                            |
| Default Value       | <code>localhost:1186</code>                       |

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=#`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code>      |
| Status Variable     | <code>Ndb_cluster_node_id</code> |
| Scope               | Global                           |
| Dynamic             | No                               |
| Type                | Integer                          |
| Minimum Value       | <code>1</code>                   |
| Maximum Value       | <code>255</code>                 |
| Maximum Value       | <code>63</code>                  |

Set this MySQL server's node ID in an NDB Cluster.

The `--ndb-nodeid` option overrides any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.

In addition, if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” `[mysqld]` or `[api]` section in the

file (that is, a section without a `NodeId` or `Id` parameter specified). This is also true if the node ID is specified as part of the connection string.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for NDB Cluster SQL nodes, see [Section 21.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `--ndb-optimization-delay=milliseconds`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--ndb-optimization-delay=#</code> |
| System Variable     | <code>ndb_optimization_delay</code>     |
| Scope               | Global                                  |
| Dynamic             | Yes                                     |
| Type                | Integer                                 |
| Default Value       | <code>10</code>                         |
| Minimum Value       | <code>0</code>                          |
| Maximum Value       | <code>100000</code>                     |

Set the number of milliseconds to wait between sets of rows by `OPTIMIZE TABLE` statements on NDB tables. The default is 10.

- `--ndb-optimized-node-selection`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-transid-mysql-connection-map=state`

|                     |                                                           |
|---------------------|-----------------------------------------------------------|
| Command-Line Format | <code>--ndb-transid-mysql-connection-map[=state]</code>   |
| Type                | Enumeration                                               |
| Default Value       | <code>ON</code>                                           |
| Valid Values        | <code>ON</code><br><code>OFF</code><br><code>FORCE</code> |

Enables or disables the plugin that handles the `ndb_transid_mysql_connection_map` table in the `INFORMATION_SCHEMA` database. Takes one of the values `ON`, `OFF`, or `FORCE`. `ON` (the default) enables the plugin. `OFF` disables the plugin, which makes `ndb_transid_mysql_connection_map` inaccessible. `FORCE` keeps the MySQL Server from starting if the plugin fails to load and start.

You can see whether the `ndb_transid_mysql_connection_map` table plugin is running by checking the output of `SHOW PLUGINS`.

- `--ndb-wait-connected=seconds`

|                     |                                     |      |
|---------------------|-------------------------------------|------|
| Command-Line Format | <code>--ndb-wait-connected=#</code> | 3167 |
| System Variable     | <code>ndb_wait_connected</code>     |      |

|               |          |
|---------------|----------|
| Scope         | Global   |
| Dynamic       | No       |
| Type          | Integer  |
| Default Value | 30       |
| Minimum Value | 0        |
| Maximum Value | 31536000 |

This option sets the period of time that the MySQL server waits for connections to NDB Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds. The default value is 30.

- `--ndb-wait-setup=seconds`

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | <code>--ndb-wait-setup=#</code> |
| System Variable     | <code>ndb_wait_setup</code>     |
| Scope               | Global                          |
| Dynamic             | No                              |
| Type                | Integer                         |
| Default Value       | 30                              |
| Default Value       | 30                              |
| Default Value       | 15                              |
| Default Value       | 15                              |
| Minimum Value       | 0                               |
| Maximum Value       | 31536000                        |

This variable shows the period of time that the MySQL server waits for the `NDB` storage engine to complete setup before timing out and treating `NDB` as unavailable. The time is specified in seconds. The default value is 30.

- `--skip-ndbcluster`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--skip-ndbcluster</code> |
|---------------------|--------------------------------|

Disable the `NDBCLUSTER` storage engine. This is the default for binaries that were built with `NDBCLUSTER` storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See [Section 21.3.1, “Quick Test Setup of NDB Cluster”](#), for an example.

## NDB Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to NDB Cluster and the `NDB` storage engine. For system variables not specific to NDB Cluster, see [Section 5.1.7, “Server System Variables”](#). For general information on using system variables, see [Section 5.1.8, “Using System Variables”](#).

- `ndb_autoincrement_prefetch_sz`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-autoincrement-prefetch-sz=#</code> |
| System Variable     | <code>ndb_autoincrement_prefetch_sz</code>     |
| Scope               | Global, Session                                |
| Dynamic             | Yes                                            |
| Type                | Integer                                        |

|               |                    |
|---------------|--------------------|
| Default Value | <code>1</code>     |
| Minimum Value | <code>1</code>     |
| Maximum Value | <code>65536</code> |

Determines the probability of gaps in an autoincremented column. Set it to `1` to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers are used in a batch of inserts.

This variable affects only the number of `AUTO_INCREMENT` IDs that are fetched between statements; within a given statement, at least 32 IDs are obtained at a time.

### Important

This variable does not affect inserts performed using `INSERT ... SELECT`.

- `ndb_cache_check_time`

|                     |                                       |
|---------------------|---------------------------------------|
| Command-Line Format | <code>--ndb-cache-check-time=#</code> |
| Deprecated          | <code>5.7.20</code>                   |
| System Variable     | <code>ndb_cache_check_time</code>     |
| Scope               | Global                                |
| Dynamic             | Yes                                   |
| Type                | Integer                               |
| Default Value       | <code>0</code>                        |

The number of milliseconds that elapse between checks of NDB Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

### Note

The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `ndb_cache_check_time`.

- `ndb_clear_apply_status`

|                     |                                                  |
|---------------------|--------------------------------------------------|
| Command-Line Format | <code>--ndb-clear-apply-status[={OFF ON}]</code> |
| System Variable     | <code>ndb_clear_apply_status</code>              |
| Scope               | Global                                           |
| Dynamic             | Yes                                              |
| Type                | Boolean                                          |
| Default Value       | <code>ON</code>                                  |

By the default, executing `RESET SLAVE` causes an NDB Cluster replica to purge all rows from its `ndb_apply_status` table. You can disable this by setting `ndb_clear_apply_status=OFF`.

- `ndb_data_node_neighbour`

|                     |                                          |
|---------------------|------------------------------------------|
| Command-Line Format | <code>--ndb-data-node-neighbour=#</code> |
|---------------------|------------------------------------------|

|                 |                                         |
|-----------------|-----------------------------------------|
| Introduced      | 5.7.12-ndb-7.5.2                        |
| System Variable | <a href="#">ndb_data_node_neighbour</a> |
| Scope           | Global                                  |
| Dynamic         | Yes                                     |
| Type            | Integer                                 |
| Default Value   | 0                                       |
| Minimum Value   | 0                                       |
| Maximum Value   | 255                                     |

Sets the ID of a “nearest” data node—that is, a preferred nonlocal data node is chosen to execute the transaction, rather than one running on the same host as the SQL or API node. This used to ensure that when a fully replicated table is accessed, we access it on this data node, to ensure that the local copy of the table is always used whenever possible. This can also be used for providing hints for transactions.

This can improve data access times in the case of a node that is physically closer than and thus has higher network throughput than others on the same host.

See [Section 13.1.18.9, “Setting NDB\\_TABLE Options”](#), for further information.

Added in NDB 7.5.2.

#### Note

An equivalent method `set_data_node_neighbour()` is provided for use in NDB API applications.

- [ndb\\_default\\_column\\_format](#)

|                                                        |                                                          |
|--------------------------------------------------------|----------------------------------------------------------|
| Command-Line Format                                    | <code>--ndb-default-column-format={FIXED DYNAMIC}</code> |
| Introduced                                             | 5.7.11-ndb-7.5.1                                         |
| System Variable                                        | <a href="#">ndb_default_column_format</a>                |
| Scope                                                  | Global                                                   |
| Dynamic                                                | Yes                                                      |
| Type                                                   | Enumeration                                              |
| Default Value (≥ 5.7.16-ndb-7.5.4)                     | <code>FIXED</code>                                       |
| Default Value (≥ 5.7.11-ndb-7.5.1, ≤ 5.7.13-ndb-7.5.3) | <code>DYNAMIC</code>                                     |
| Valid Values                                           | <code>FIXED</code><br><code>DYNAMIC</code>               |

In NDB 7.5.1 and later, sets the default `COLUMN_FORMAT` and `ROW_FORMAT` for new tables (see [Section 13.1.18, “CREATE TABLE Statement”](#)).

In NDB 7.5.1, the default for this variable was `DYNAMIC`; in NDB 7.5.4, the default was changed to `FIXED` to maintain backwards compatibility with older release series (Bug #24487363).

- [ndb\\_deferred\\_constraints](#)

|                     |                                           |
|---------------------|-------------------------------------------|
| Command-Line Format | <code>--ndb-deferred-constraints=#</code> |
|---------------------|-------------------------------------------|

|                 |                                       |
|-----------------|---------------------------------------|
| System Variable | <code>ndb_deferred_constraints</code> |
| Scope           | Global, Session                       |
| Dynamic         | Yes                                   |
| Type            | Integer                               |
| Default Value   | 0                                     |
| Minimum Value   | 0                                     |
| Maximum Value   | 1                                     |

Controls whether or not constraint checks are deferred, where these are supported. 0 is the default.

This variable is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- [ndb\\_distribution](#)

|                     |                                                   |
|---------------------|---------------------------------------------------|
| Command-Line Format | <code>--ndb-distribution={KEYHASH LINHASH}</code> |
| System Variable     | <code>ndb_distribution</code>                     |
| Scope               | Global                                            |
| Dynamic             | Yes                                               |
| Type                | Enumeration                                       |
| Default Value       | KEYHASH                                           |
| Valid Values        | LINHASH<br>KEYHASH                                |

Controls the default distribution method for NDB tables. Can be set to either of KEYHASH (key hashing) or LINHASH (linear hashing). KEYHASH is the default.

- [ndb\\_eventbuffer\\_free\\_percent](#)

|                     |                                               |
|---------------------|-----------------------------------------------|
| Command-Line Format | <code>--ndb-eventbuffer-free-percent=#</code> |
| System Variable     | <code>ndb_eventbuffer_free_percent</code>     |
| Scope               | Global                                        |
| Dynamic             | Yes                                           |
| Type                | Integer                                       |
| Default Value       | 20                                            |
| Minimum Value       | 1                                             |
| Maximum Value       | 99                                            |

Sets the percentage of the maximum memory allocated to the event buffer (ndb\_eventbuffer\_max\_alloc) that should be available in event buffer after reaching the maximum, before starting to buffer again.

- [ndb\\_eventbuffer\\_max\\_alloc](#)

|                     |                                            |
|---------------------|--------------------------------------------|
| Command-Line Format | <code>--ndb-eventbuffer-max-alloc=#</code> |
| System Variable     | <code>ndb_eventbuffer_max_alloc</code>     |
| Scope               | Global                                     |
| Dynamic             | Yes                                        |
| Type                | Integer                                    |

|               |            |
|---------------|------------|
| Default Value | 0          |
| Minimum Value | 0          |
| Maximum Value | 4294967295 |

Sets the maximum amount memory (in bytes) that can be allocated for buffering events by the NDB API. 0 means that no limit is imposed, and is the default.

- [ndb\\_extra\\_logging](#)

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>ndb_extra_logging=#</code>  |
| System Variable     | <a href="#">ndb_extra_logging</a> |
| Scope               | Global                            |
| Dynamic             | Yes                               |
| Type                | Integer                           |
| Default Value       | 1                                 |

This variable enables recording in the MySQL error log of information specific to the [NDB](#) storage engine.

When this variable is set to 0, the only information specific to [NDB](#) that is written to the MySQL error log relates to transaction handling. If it set to a value greater than 0 but less than 10, [NDB](#) table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other [NDB](#) errors and information. If the value is set to 10 or more, information about [NDB](#) internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log. The default is 1.

- [ndb\\_force\\_send](#)

|                     |                                          |
|---------------------|------------------------------------------|
| Command-Line Format | <code>--ndb-force-send[={OFF ON}]</code> |
| System Variable     | <a href="#">ndb_force_send</a>           |
| Scope               | Global, Session                          |
| Dynamic             | Yes                                      |
| Type                | Boolean                                  |
| Default Value       | ON                                       |

Forces sending of buffers to [NDB](#) immediately, without waiting for other threads. Defaults to [ON](#).

- [ndb\\_fully\\_replicated](#)

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-fully-replicated[={OFF ON}]</code> |
| Introduced          | 5.7.12-ndb-7-5-2                               |
| System Variable     | <a href="#">ndb_fully_replicated</a>           |
| Scope               | Global, Session                                |
| Dynamic             | Yes                                            |
| Type                | Boolean                                        |
| Default Value       | OFF                                            |

Determines whether new [NDB](#) tables are fully replicated. This setting can be overridden for an individual table using `COMMENT= "NDB_TABLE=FULLY_REPLICATED=..."` in a `CREATE TABLE`

or `ALTER TABLE` statement; see [Section 13.1.18.9, “Setting NDB\\_TABLE Options”](#), for syntax and other information.

Added in NDB 7.5.2.

- `ndb_index_stat_enable`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--ndb-index-stat-enable[={OFF ON}]</code> |
| System Variable     | <code>ndb_index_stat_enable</code>              |
| Scope               | Global, Session                                 |
| Dynamic             | Yes                                             |
| Type                | Boolean                                         |
| Default Value       | <code>ON</code>                                 |

Use `NDB` index statistics in query optimization. The default is `ON`.

- `ndb_index_stat_option`

|                     |                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Command-Line Format | <code>--ndb-index-stat-option=value</code>                                                                                                                                                                                                                                           |
| System Variable     | <code>ndb_index_stat_option</code>                                                                                                                                                                                                                                                   |
| Scope               | Global, Session                                                                                                                                                                                                                                                                      |
| Dynamic             | Yes                                                                                                                                                                                                                                                                                  |
| Type                | String                                                                                                                                                                                                                                                                               |
| Default Value       | <code>loop_checkon=1000ms,loop_idle=1000ms,loop_busy=100ms,<br/>update_batch=1,read_batch=4,idle_batch=32,check_batch=32,<br/>check_delay=1m,delete_batch=8,clean_delay=0,error_batch=4,<br/>error_delay=1m,evict_batch=8,evict_delay=1m,cache_limit=32M,<br/>cache_lowpct=90</code> |

This variable is used for providing tuning options for NDB index statistics generation. The list consist of comma-separated name-value pairs of option names and values, and this list must not contain any space characters.

Options not used when setting `ndb_index_stat_option` are not changed from their default values. For example, you can set `ndb_index_stat_option = 'loop_idle=1000ms,cache_limit=32M'`.

Time values can be optionally suffixed with `h` (hours), `m` (minutes), or `s` (seconds). Millisecond values can optionally be specified using `ms`; millisecond values cannot be specified using `h`, `m`, or `s`.) Integer values can be suffixed with `K`, `M`, or `G`.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

**Table 21.18 `ndb_index_stat_option` options and values**

| Name                      | Description                             | Default/Units | Minimum/Maximum |
|---------------------------|-----------------------------------------|---------------|-----------------|
| <code>loop_enable</code>  |                                         | 1000 ms       | 0/4G            |
| <code>loop_idle</code>    | Time to sleep when idle                 | 1000 ms       | 0/4G            |
| <code>loop_busy</code>    | Time to sleep when more work is waiting | 100 ms        | 0/4G            |
| <code>update_batch</code> |                                         | 1             | 0/4G            |
| <code>read_batch</code>   |                                         | 4             | 1/4G            |

| Name         | Description                                                                                                                                            | Default/Units | Minimum/Maximum |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-----------------|
| idle_batch   |                                                                                                                                                        | 32            | 1/4G            |
| check_batch  |                                                                                                                                                        | 8             | 1/4G            |
| check_delay  | How often to check for new statistics                                                                                                                  | 10 m          | 1/4G            |
| delete_batch |                                                                                                                                                        | 8             | 0/4G            |
| clean_delay  |                                                                                                                                                        | 1 m           | 0/4G            |
| error_batch  |                                                                                                                                                        | 4             | 1/4G            |
| error_delay  |                                                                                                                                                        | 1 m           | 1/4G            |
| evict_batch  |                                                                                                                                                        | 8             | 1/4G            |
| evict_delay  | Clean LRU cache, from read time                                                                                                                        | 1 m           | 0/4G            |
| cache_limit  | Maximum amount of memory in bytes used for cached index statistics by this <code>mysqld</code> ; clean up the cache when this is exceeded.             | 32 M          | 0/4G            |
| cache_lowpct |                                                                                                                                                        | 90            | 0/100           |
| zero_total   | Setting this to 1 resets all accumulating counters in <code>ndb_index_stat_status</code> to 0. This option value is also reset to 0 when this is done. | 0             | 0/1             |

- `ndb_join_pushdown`

|                 |                                |
|-----------------|--------------------------------|
| System Variable | <code>ndb_join_pushdown</code> |
| Scope           | Global, Session                |
| Dynamic         | Yes                            |
| Type            | Boolean                        |
| Default Value   | <code>ON</code>                |

This variable controls whether joins on `NDB` tables are pushed down to the NDB kernel (data nodes). Previously, a join was handled using multiple accesses of `NDB` by the SQL node; however, when `ndb_join_pushdown` is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with

a single, merged result being returned to `mysqld`. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, `ndb_join_pushdown` is enabled.

**Conditions for NDB pushdown joins.** In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use *exactly* the same data type.

This means that expressions such as `t1.a = t2.a + constant` cannot be pushed down, and that (for example) a join on an `INT` column and a `BIGINT` column also cannot be pushed down.

2. Queries referencing `BLOB` or `TEXT` columns are not supported.
3. Explicit locking is not supported; however, the `NDB` storage engine's characteristic implicit row-based locking is enforced.

This means that a join using `FOR UPDATE` cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the `ref`, `eq_ref`, or `const` access methods, or some combination of these methods.

Outer joined child tables can only be pushed using `eq_ref`.

If the root of the pushed join is an `eq_ref` or `const`, only child tables joined by `eq_ref` can be appended. (A table joined by `ref` is likely to become the root of another pushed join.)

If the query optimizer decides on `Using join cache` for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by `[LINEAR] HASH`, `LIST`, or `RANGE` currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with `EXPLAIN`; when the join can be pushed down, you can see references to the `pushed join` in the `Extra` column of the output, as shown in this example:

```
mysql> EXPLAIN
-> SELECT e.first_name, e.last_name, t.title, d.dept_name
-> FROM employees e
-> JOIN dept_emp de ON e.emp_no=de.emp_no
-> JOIN departments d ON d.dept_no=de.dept_no
-> JOIN titles t ON e.emp_no=t.emp_no\G

 id: 1
 select_type: SIMPLE
 table: d

 table: t
 type: ref
possible_keys: PRIMARY,emp_no
 key: emp_no
 key_len: 4
 ref: employees.de.emp_no
 rows: 19
Extra: Child of 'e' in pushed join@1
4 rows in set (0.00 sec)

```

### Note

If inner joined child tables are joined by `ref`, and the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables `Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`, `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads`.
  2. The counters in the `ndbinfo.counters` table that belong to the `DBSPJ` kernel block.
- `ndb_log_apply_status`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-log-apply-status[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_apply_status</code>              |
| Scope               | Global                                         |
| Dynamic             | No                                             |
| Type                | Boolean                                        |
| Default Value       | <code>OFF</code>                               |

A read-only variable which shows whether the server was started with the `--ndb-log-apply-status` option.

- `ndb_log_bin`

|                     |                                       |
|---------------------|---------------------------------------|
| Command-Line Format | <code>--ndb-log-bin[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_bin</code>              |
| Scope               | Global, Session                       |
| Dynamic             | No                                    |
| Type                | Boolean                               |

|               |                 |
|---------------|-----------------|
| Default Value | <code>ON</code> |
|---------------|-----------------|

Causes updates to `NDB` tables to be written to the binary log. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. `ndb_log_bin` defaults to `1` (`ON`); normally, there is never any need to change this value in a production environment.

- `ndb_log_binlog_index`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-log-binlog-index[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_binlog_index</code>              |
| Scope               | Global                                         |
| Dynamic             | Yes                                            |
| Type                | Boolean                                        |
| Default Value       | <code>ON</code>                                |

Causes a mapping of epochs to positions in the binary log to be inserted into the `ndb_binlog_index` table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. (In addition, `ndb_log_bin` must not be disabled.) `ndb_log_binlog_index` defaults to `1` (`ON`); normally, there is never any need to change this value in a production environment.

- `ndb_log_empty_epochs`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-log-empty-epochs[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_empty_epochs</code>              |
| Scope               | Global                                         |
| Dynamic             | Yes                                            |
| Type                | Boolean                                        |
| Default Value       | <code>OFF</code>                               |

When this variable is set to `0`, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

- `ndb_log_empty_update`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-log-empty-update[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_empty_update</code>              |
| Scope               | Global                                         |
| Dynamic             | Yes                                            |
| Type                | Boolean                                        |
| Default Value       | <code>OFF</code>                               |

When this variable is set to `ON` (`1`), update transactions with no changes are written to the binary log, even when `log_slave_updates` is enabled.

- `ndb_log_exclusive_reads`

|                     |                                                   |
|---------------------|---------------------------------------------------|
| Command-Line Format | <code>--ndb-log-exclusive-reads[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_exclusive_reads</code>              |
| Scope               | Global, Session                                   |
| Dynamic             | Yes                                               |

|               |         |
|---------------|---------|
| Type          | Boolean |
| Default Value | 0       |

This variable determines whether primary key reads are logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. To enable these locks, set the value of `ndb_log_exclusive_reads` to 1. 0, which disables such locking, is the default.

For more information, see [Read conflict detection and resolution](#).

- `ndb_log_orig`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--ndb-log-orig[={OFF ON}]</code> |
| System Variable     | <code>ndb_log_orig</code>              |
| Scope               | Global                                 |
| Dynamic             | No                                     |
| Type                | Boolean                                |
| Default Value       | OFF                                    |

Shows whether the originating server ID and epoch are logged in the `ndb_binlog_index` table. Set using the `--ndb-log-orig` server option.

- `ndb_log_transaction_id`

|                 |                                     |
|-----------------|-------------------------------------|
| System Variable | <code>ndb_log_transaction_id</code> |
| Scope           | Global                              |
| Dynamic         | No                                  |
| Type            | Boolean                             |
| Default Value   | OFF                                 |

This read-only, Boolean system variable shows whether a replica `mysqld` writes NDB transaction IDs in the binary log (required to use “active-active” NDB Cluster Replication with `NDB$EPOCH_TRANS()` conflict detection). To change the setting, use the `--ndb-log-transaction-id` option.

`ndb_log_transaction_id` is not supported in mainline MySQL Server 5.7.

For more information, see [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `ndb_optimized_node_selection`

|                     |                                               |
|---------------------|-----------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection=#</code> |
| System Variable     | <code>ndb_optimized_node_selection</code>     |
| Scope               | Global                                        |
| Dynamic             | No                                            |
| Type                | Integer                                       |
| Default Value       | 3                                             |
| Minimum Value       | 0                                             |

|               |   |
|---------------|---|
| Maximum Value | 3 |
|---------------|---|

There are two forms of optimized node selection, described here:

1. The SQL node uses *proximity* to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`, followed by TCP connection from a host other than `localhost`.
2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values `0`, `1`, `2`, or `3`. `3` is the default. These values affect node selection as follows:

- `0`: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node.
- `1`: Proximity to the SQL node is used to determine the transaction coordinator.
- `2`: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to `0`.
- `3`: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior.)

Proximity is determined as follows:

1. Start with the value set for the `Group` parameter (default 55).
2. For an API node sharing the same host with other API nodes, decrement the value by 1. Assuming the default value for `Group`, the effective value for data nodes on same host as the API node is 54, and for remote data nodes 55.
3. (*NDB 7.5.2 and later:*) Setting `ndb_data_node_neighbour` further decreases the effective `Group` value by 50, causing this node to be regarded as the nearest node. This is needed only when all data nodes are on hosts other than that hosts the API node and it is desirable to dedicate one of them to the API node. In normal cases, the default adjustment described previously is sufficient.

Frequent changes in `ndb_data_node_neighbour` are not advisable, since this changes the state of the cluster connection and thus may disrupt the selection algorithm for new transactions from each thread until it stabilizes.

- `ndb_read_backup`

|                     |                                               |
|---------------------|-----------------------------------------------|
| Command-Line Format | <code>--ndb-read-backup [= {OFF   ON}]</code> |
| Introduced          | 5.7.12-ndb-7.5.2                              |
| System Variable     | <code>ndb_read_backup</code>                  |
| Scope               | Global                                        |
| Dynamic             | Yes                                           |
| Type                | Boolean                                       |

|               |                  |
|---------------|------------------|
| Default Value | <code>OFF</code> |
|---------------|------------------|

Enable read from any fragment replica for any [NDB](#) table subsequently created; doing so greatly improves the table read performance at a relatively small cost to writes.

To enable or disable read from any fragment replica for an individual table, you can set the [NDB\\_TABLE](#) option `READ_BACKUP` for the table accordingly, in a `CREATE TABLE` or `ALTER TABLE` statement; see [Section 13.1.18.9, “Setting NDB\\_TABLE Options”](#), for more information.

Added in NDB 7.5.2.

- [`ndb\_recv\_thread\_activation\_threshold`](#)

|                     |                                                           |
|---------------------|-----------------------------------------------------------|
| Command-Line Format | <code>--ndb-recv-thread-activation-threshold=#</code>     |
| System Variable     | <code>ndb_recv_thread_activation_threshold</code>         |
| Scope               | Global                                                    |
| Dynamic             | Yes                                                       |
| Type                | Integer                                                   |
| Default Value       | <code>8</code>                                            |
| Minimum Value       | <code>0</code> ( <code>MIN_ACTIVATION_THRESHOLD</code> )  |
| Maximum Value       | <code>16</code> ( <code>MAX_ACTIVATION_THRESHOLD</code> ) |

When this number of concurrently active threads is reached, the receive thread takes over polling of the cluster connection.

This variable is global in scope. It can also be set at startup.

- [`ndb\_recv\_thread\_cpu\_mask`](#)

|                     |                                              |
|---------------------|----------------------------------------------|
| Command-Line Format | <code>--ndb-recv-thread-cpu-mask=mask</code> |
| System Variable     | <code>ndb_recv_thread_cpu_mask</code>        |
| Scope               | Global                                       |
| Dynamic             | Yes                                          |
| Type                | Bitmap                                       |
| Default Value       | [empty]                                      |

CPU mask for locking receiver threads to specific CPUs. This is specified as a hexadecimal bitmask. For example, `0x33` means that one CPU is used per receiver thread. An empty string is the default; setting `ndb_recv_thread_cpu_mask` to this value removes any receiver thread locks previously set.

This variable is global in scope. It can also be set at startup.

- [`ndb\_report\_thresh\_binlog\_epoch\_slip`](#)

|                                    |                                                      |
|------------------------------------|------------------------------------------------------|
| Command-Line Format                | <code>--ndb-report-thresh-binlog-epoch-slip=#</code> |
| System Variable                    | <code>ndb_report_thresh_binlog_epoch_slip</code>     |
| Scope                              | Global                                               |
| Dynamic                            | Yes                                                  |
| Type                               | Integer                                              |
| Default Value (≥ 5.7.16-ndb-7.5.4) | <code>10</code>                                      |

|                                    |     |
|------------------------------------|-----|
| Default Value (≤ 5.7.13-ndb-7.5.3) | 3   |
| Minimum Value                      | 0   |
| Maximum Value                      | 256 |

In NDB 7.5.4 and later, this represents the threshold for the number of epochs completely buffered in the event buffer, but not yet consumed by the binlog injector thread. When this degree of slippage (lag) is exceeded, an event buffer status message is reported, with `BUFFERED_EPOCHS_OVER_THRESHOLD` supplied as the reason (see [Section 21.5.2.3, “Event Buffer Reporting in the Cluster Log”](#)). Slip is increased when an epoch is received from data nodes and buffered completely in the event buffer; it is decreased when an epoch is consumed by the binlog injector thread, it is reduced. Empty epochs are buffered and queued, and so included in this calculation only when this is enabled using the `Ndb::setEventBufferQueueEmptyEpoch()` method from the NDB API.

Prior to NDB 7.5.4, the value of this variable served as a threshold for the number of epochs to be behind before reporting binary log status. In these previous releases, a value of 3—the default—means that if the difference between which epoch has been received from the storage nodes and which epoch has been applied to the binary log is 3 or more, a status message is then sent to the cluster log.

- [ndb\\_report\\_thresh\\_binlog\\_mem\\_usage](#)

|                     |                                                     |
|---------------------|-----------------------------------------------------|
| Command-Line Format | <code>--ndb-report-thresh-binlog-mem-usage=#</code> |
| System Variable     | <code>ndb_report_thresh_binlog_mem_usage</code>     |
| Scope               | Global                                              |
| Dynamic             | Yes                                                 |
| Type                | Integer                                             |
| Default Value       | 10                                                  |
| Minimum Value       | 0                                                   |
| Maximum Value       | 10                                                  |

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message is sent to the cluster log.

- [ndb\\_row\\_checksum](#)

|                 |                               |
|-----------------|-------------------------------|
| Introduced      | 5.7.23-ndb-7.6.8              |
| System Variable | <code>ndb_row_checksum</code> |
| Scope           | Global, Session               |
| Dynamic         | Yes                           |
| Type            | Integer                       |
| Default Value   | 1                             |
| Minimum Value   | 0                             |
| Maximum Value   | 1                             |

Traditionally, `NDB` has created tables with row checksums, which checks for hardware issues at the expense of performance. Setting `ndb_row_checksum` to 0 means that row checksums are *not* used for new or altered tables, which has a significant impact on performance for all types of queries. This variable is set to 1 by default, to provide backward-compatible behavior.

- [ndb\\_show\\_foreign\\_key\\_mock\\_tables](#)

|                     |                                                            |
|---------------------|------------------------------------------------------------|
| Command-Line Format | <code>--ndb-show-foreign-key-mock-tables[={OFF ON}]</code> |
| System Variable     | <code>ndb_show_foreign_key_mock_tables</code>              |
| Scope               | Global                                                     |
| Dynamic             | Yes                                                        |
| Type                | Boolean                                                    |
| Default Value       | <code>OFF</code>                                           |

Show the mock tables used by NDB to support `foreign_key_checks=0`. When this is enabled, extra warnings are shown when creating and dropping the tables. The real (internal) name of the table can be seen in the output of `SHOW CREATE TABLE`.

- `ndb_slave_conflict_role`

|                     |                                                                                          |
|---------------------|------------------------------------------------------------------------------------------|
| Command-Line Format | <code>--ndb-slave-conflict-role=value</code>                                             |
| System Variable     | <code>ndb_slave_conflict_role</code>                                                     |
| Scope               | Global                                                                                   |
| Dynamic             | Yes                                                                                      |
| Type                | Enumeration                                                                              |
| Default Value       | <code>NONE</code>                                                                        |
| Valid Values        | <code>NONE</code><br><code>PRIMARY</code><br><code>SECONDARY</code><br><code>PASS</code> |

Determine the role of this SQL node (and NDB Cluster) in a circular (“active-active”) replication setup. `ndb_slave_conflict_role` can take any one of the values `PRIMARY`, `SECONDARY`, `PASS`, or `NULL` (the default). The replica SQL thread must be stopped before you can change `ndb_slave_conflict_role`. In addition, it is not possible to change directly between `PASS` and either of `PRIMARY` or `SECONDARY` directly; in such cases, you must ensure that the SQL thread is stopped, then execute `SET @@GLOBAL.ndb_slave_conflict_role = 'NONE'` first.

For more information, see Section 21.6.11, “NDB Cluster Replication Conflict Resolution”.

- `ndb_table_no_logging`

|                 |                                   |
|-----------------|-----------------------------------|
| System Variable | <code>ndb_table_no_logging</code> |
| Scope           | Session                           |
| Dynamic         | Yes                               |
| Type            | Boolean                           |
| Default Value   | <code>OFF</code>                  |

When this variable is set to `ON` or `1`, it causes NDB tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using `ENGINE NDB` when `ndb_table_no_logging` is enabled, and continues to apply for the lifetime of the table, even if `ndb_table_no_logging` is later changed. Suppose that `A`, `B`, `C`, and `D` are tables that we create (and perhaps also alter), and that we also change the setting for `ndb_table_no_logging` as shown here:

```
SET @@ndb_table_no_logging = 1;
```

```

CREATE TABLE A ... ENGINE NDB;

CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;

ALTER TABLE B ENGINE NDB;

SET @@ndb_table_no_logging = 0;

CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;

SET @@ndb_table_no_logging = 1;

```

After the previous sequence of events, tables **A** and **B** are not checkpointed; **A** was created with `ENGINE NDB` and **B** was altered to use `NDB`, both while `ndb_table_no_logging` was enabled. However, tables **C** and **D** are logged; **C** was altered to use `NDB` and **D** was created using `ENGINE NDB`, both while `ndb_table_no_logging` was disabled. Setting `ndb_table_no_logging` back to `1` or `ON` does *not* cause table **C** or **D** to be checkpointed.

#### Note

`ndb_table_no_logging` has no effect on the creation of `NDB` table schema files; to suppress these, use `ndb_table_temporary` instead.

- `ndb_table_temporary`

|                 |                                  |
|-----------------|----------------------------------|
| System Variable | <code>ndb_table_temporary</code> |
| Scope           | Session                          |
| Dynamic         | Yes                              |
| Type            | Boolean                          |
| Default Value   | <code>OFF</code>                 |

When set to `ON` or `1`, this variable causes `NDB` tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

#### Note

Setting this variable currently has no effect. This is a known issue; see Bug #34036.

- `ndb_use_copying_alter_table`

|                 |                                          |
|-----------------|------------------------------------------|
| System Variable | <code>ndb_use_copying_alter_table</code> |
| Scope           | Global, Session                          |
| Dynamic         | No                                       |

Forces `NDB` to use copying of tables in the event of problems with online `ALTER TABLE` operations. The default value is `OFF`.

- `ndb_use_exact_count`

|                 |                                  |
|-----------------|----------------------------------|
| System Variable | <code>ndb_use_exact_count</code> |
| Scope           | Global, Session                  |
| Dynamic         | Yes                              |
| Type            | Boolean                          |

|               |                  |
|---------------|------------------|
| Default Value | <code>OFF</code> |
|---------------|------------------|

Forces NDB to use a count of records during `SELECT COUNT(*)` query planning to speed up this type of query. The default value is `OFF`, which allows for faster queries overall.

- `ndb_use_transactions`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-use-transactions[={OFF ON}]</code> |
| System Variable     | <code>ndb_use_transactions</code>              |
| Scope               | Global, Session                                |
| Dynamic             | Yes                                            |
| Type                | Boolean                                        |
| Default Value       | <code>ON</code>                                |

You can disable NDB transaction support by setting this variable's values to `OFF` (not recommended). The default is `ON`.

- `ndb_version`

|                 |                          |
|-----------------|--------------------------|
| System Variable | <code>ndb_version</code> |
| Scope           | Global                   |
| Dynamic         | No                       |
| Type            | String                   |
| Default Value   |                          |

NDB engine version, as a composite integer.

- `ndb_version_string`

|                 |                                 |
|-----------------|---------------------------------|
| System Variable | <code>ndb_version_string</code> |
| Scope           | Global                          |
| Dynamic         | No                              |
| Type            | String                          |
| Default Value   |                                 |

NDB engine version in `ndb-x.y.z` format.

- `server_id_bits`

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | <code>--server-id-bits=#</code> |
| System Variable     | <code>server_id_bits</code>     |
| Scope               | Global                          |
| Dynamic             | No                              |
| Type                | Integer                         |
| Default Value       | <code>32</code>                 |
| Minimum Value       | <code>7</code>                  |
| Maximum Value       | <code>32</code>                 |

This variable indicates the number of least significant bits within the 32-bit `server_id` which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing

user data generated by applications using the NDB API's Event API within the `AnyValue` of an `OperationOptions` structure (NDB Cluster uses the `AnyValue` to store the server ID).

When extracting the effective server ID from `server_id` for purposes such as detection of replication loops, the server ignores the remaining bits. The `server_id_bits` variable is used to mask out any irrelevant bits of `server_id` in the I/O and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by `mysqlbinlog`, provided that it is run with its own `server_id_bits` variable set to 32 (the default).

If the value of `server_id` greater than or equal to 2 to the power of `server_id_bits`; otherwise, `mysqld` refuses to start.

This system variable is supported only by NDB Cluster. It is not supported in the standard MySQL 5.7 Server.

- `slave_allow_batching`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--slave-allow-batching[={OFF ON}]</code> |
| System Variable     | <code>slave_allow_batching</code>              |
| Scope               | Global                                         |
| Dynamic             | Yes                                            |
| Type                | Boolean                                        |
| Default Value       | <code>OFF</code>                               |

Whether or not batched updates are enabled on NDB Cluster replicas.

Setting this variable has an effect only when using replication with the `NDB` storage engine; in MySQL Server 5.7, it is present but does nothing. For more information, see [Section 21.6.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”](#).

- `transaction_allow_batching`

|                 |                                         |
|-----------------|-----------------------------------------|
| System Variable | <code>transaction_allow_batching</code> |
| Scope           | Session                                 |
| Dynamic         | Yes                                     |
| Type            | Boolean                                 |
| Default Value   | <code>OFF</code>                        |

When set to `1` or `ON`, this variable enables batching of statements within the same transaction. To use this variable, `autocommit` must first be disabled by setting it to `0` or `OFF`; otherwise, setting `transaction_allow_batching` has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the “before” image. You should ensure that any pending transactions are committed (using an explicit `COMMIT` if desired) before issuing a `SELECT`.

**Important**

`transaction_allow_batching` should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable is currently supported for NDB Cluster only.

The system variables in the following list all relate to the `ndbinfo` information database.

- [ndbinfo\\_database](#)

|                 |                                  |
|-----------------|----------------------------------|
| System Variable | <a href="#">ndbinfo_database</a> |
| Scope           | Global                           |
| Dynamic         | No                               |
| Type            | String                           |
| Default Value   | <a href="#">ndbinfo</a>          |

Shows the name used for the [NDB](#) information database; the default is [ndbinfo](#). This is a read-only variable whose value is determined at compile time.

- [ndbinfo\\_max\\_bytes](#)

|                     |                                    |
|---------------------|------------------------------------|
| Command-Line Format | <code>--ndbinfo-max-bytes=#</code> |
| System Variable     | <a href="#">ndbinfo_max_bytes</a>  |
| Scope               | Global, Session                    |
| Dynamic             | Yes                                |
| Type                | Integer                            |
| Default Value       | <a href="#">0</a>                  |

Used in testing and debugging only.

- [ndbinfo\\_max\\_rows](#)

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--ndbinfo-max-rows=#</code> |
| System Variable     | <a href="#">ndbinfo_max_rows</a>  |
| Scope               | Global, Session                   |
| Dynamic             | Yes                               |
| Type                | Integer                           |
| Default Value       | <a href="#">10</a>                |

Used in testing and debugging only.

- [ndbinfo\\_offline](#)

|                 |                                 |
|-----------------|---------------------------------|
| System Variable | <a href="#">ndbinfo_offline</a> |
| Scope           | Global                          |
| Dynamic         | Yes                             |
| Type            | Boolean                         |
| Default Value   | <a href="#">OFF</a>             |

Place the [ndbinfo](#) database into offline mode, in which tables and views can be opened even when they do not actually exist, or when they exist but have different definitions in [NDB](#). No rows are returned from such tables (or views).

- [ndbinfo\\_show\\_hidden](#)

|                     |                                               |
|---------------------|-----------------------------------------------|
| Command-Line Format | <code>--ndbinfo-show-hidden[={OFF ON}]</code> |
| System Variable     | <a href="#">ndbinfo_show_hidden</a>           |
| Scope               | Global, Session                               |
| Dynamic             | Yes                                           |

|               |           |
|---------------|-----------|
| Type          | Boolean   |
| Default Value | OFF       |
| Valid Values  | ON<br>OFF |
|               |           |

Whether or not the `ndbinfo` database's underlying internal tables are shown in the `mysql` client. The default is `OFF`.

- `ndbinfo_table_prefix`

|                 |                                   |
|-----------------|-----------------------------------|
| System Variable | <code>ndbinfo_table_prefix</code> |
| Scope           | Global                            |
| Dynamic         | No                                |
| Type            | String                            |
| Default Value   | <code>ndb\$</code>                |

The prefix used in naming the `ndbinfo` database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is `ndb$`; the prefix itself is determined at compile time.

- `ndbinfo_version`

|                 |                              |
|-----------------|------------------------------|
| System Variable | <code>ndbinfo_version</code> |
| Scope           | Global                       |
| Dynamic         | No                           |
| Type            | String                       |
| Default Value   |                              |

Shows the version of the `ndbinfo` engine in use; read-only.

## NDB Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to NDB Cluster and the `NDB` storage engine. For status variables not specific to NDB Cluster, and for general information on using status variables, see [Section 5.1.9, “Server Status Variables”](#).

- `Handler_discover`

The MySQL server can ask the `NDBCLUSTER` storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- `Ndb_api_adaptive_send_deferred_count`

Number of adaptive send calls that were not actually sent.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_deferred_count_session`

Number of adaptive send calls that were not actually sent.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_deferred_count_slave`

Number of adaptive send calls that were not actually sent by this replica.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_adaptive\_send\_forced\_count`](#)

Number of adaptive send calls using forced-send sent by this MySQL Server (SQL node).

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_adaptive\_send\_forced\_count\_session`](#)

Number of adaptive send calls using forced-send sent in this client session.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_adaptive\_send\_forced\_count\_slave`](#)

Number of adaptive send calls using forced-send sent by this replica.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_adaptive\_send\_unforced\_count`](#)

Number of adaptive send calls without forced-send sent by this MySQL server (SQL node).

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_adaptive\_send\_unforced\_count\_session`](#)

Number of adaptive send calls without forced-send sent in this client session.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_adaptive\_send\_unforced\_count\_slave`](#)

Number of adaptive send calls without forced-send sent by this replica.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_bytes\_sent\_count\_session`](#)

Amount of data (in bytes) sent to the data nodes in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_bytes\_sent\_count\_slave`](#)

Amount of data (in bytes) sent to the data nodes by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_bytes\\_sent\\_count](#)

Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_bytes\\_received\\_count\\_session](#)

Amount of data (in bytes) received from the data nodes in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_bytes\\_received\\_count\\_slave](#)

Amount of data (in bytes) received from the data nodes by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_bytes\\_received\\_count](#)

Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_event\\_data\\_count\\_injector](#)

The number of row change events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_event\\_data\\_count](#)

The number of row change events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_event\\_nodata\\_count\\_injector](#)

The number of events received, other than row change events, by the NDB binary log injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_event\\_nodata\\_count](#)

The number of events received, other than row change events, by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_event\\_bytes\\_count\\_injector](#)

The number of bytes of events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_event\\_bytes\\_count](#)

The number of bytes of events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_pk\\_op\\_count\\_session](#)

The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_pk\\_op\\_count\\_slave](#)

The number of operations by this replica based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_pk\\_op\\_count](#)

The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_pruned\\_scan\\_count\\_session](#)

The number of scans in this client session that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_pruned\\_scan\\_count\\_slave](#)

The number of scans by this replica that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_pruned\\_scan\\_count](#)

The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_range\\_scan\\_count\\_session](#)

The number of range scans that have been started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_range\\_scan\\_count\\_slave](#)

The number of range scans that have been started by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_range\\_scan\\_count](#)

The number of range scans that have been started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_read\\_row\\_count\\_session](#)

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_read\\_row\\_count\\_slave](#)

The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_read\\_row\\_count](#)

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

You should be aware that this value may not be completely accurate with regard to rows read by `SELECT COUNT(*)` queries, due to the fact that, in this case, the MySQL server actually reads pseudo-rows in the form `[table fragment ID]:[number of rows in fragment]` and sums the rows per fragment for all fragments in the table to derive an estimated count for all rows. [Ndb\\_api\\_read\\_row\\_count](#) uses this estimate and not the actual number of rows in the table.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_scan\\_batch\\_count\\_session](#)

The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_scan\\_batch\\_count\\_slave](#)

The number of batches of rows received by this replica. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_scan\\_batch\\_count](#)

The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_table\\_scan\\_count\\_session](#)

The number of table scans that have been started in this client session, including scans of internal tables.,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_table\\_scan\\_count\\_slave](#)

The number of table scans that have been started by this replica, including scans of internal tables.,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_table\\_scan\\_count](#)

The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables.,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_trans\\_abort\\_count\\_session](#)

The number of transactions aborted in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_trans\\_abort\\_count\\_slave](#)

The number of transactions aborted by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_trans\\_abort\\_count](#)

The number of transactions aborted by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_trans\\_close\\_count\\_session](#)

The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_trans\_close\_count\_slave`](#)

The number of transactions closed by this replica. This value may be greater than the sum of `Ndb_api_trans_commit_count_slave` and `Ndb_api_trans_abort_count_slave`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_trans\_close\_count`](#)

The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_trans\_commit\_count\_session`](#)

The number of transactions committed in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_trans\_commit\_count\_slave`](#)

The number of transactions committed by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_trans\_commit\_count`](#)

The number of transactions committed by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_trans\\_local\\_read\\_row\\_count\\_session](#)

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_trans\\_local\\_read\\_row\\_count\\_slave](#)

The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_trans\\_local\\_read\\_row\\_count](#)

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_trans\\_start\\_count\\_session](#)

The number of transactions started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_trans\\_start\\_count\\_slave](#)

The number of transactions started by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_trans\\_start\\_count](#)

The number of transactions started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_uk\\_op\\_count\\_session](#)

The number of operations in this client session based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_uk\_op\_count\_slave`](#)

The number of operations by this replica based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_uk\_op\_count`](#)

The number of operations by this MySQL Server (SQL node) based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_wait\_exec\_complete\_count\_session`](#)

The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_wait\_exec\_complete\_count\_slave`](#)

The number of times a thread has been blocked by this replica while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_wait\_exec\_complete\_count`](#)

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [`Ndb\_api\_wait\_meta\_request\_count\_session`](#)

The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count_slave`

The number of times a thread has been blocked by this replica waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count_session`

Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count_slave`

Total time (in nanoseconds) spent by this replica waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count`

Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_wait\\_scan\\_result\\_count\\_session](#)

The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_wait\\_scan\\_result\\_count\\_slave](#)

The number of times a thread has been blocked by this replica while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_api\\_wait\\_scan\\_result\\_count](#)

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 21.5.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb\\_cluster\\_node\\_id](#)

If the server is acting as an NDB Cluster node, then the value of this variable its node ID in the cluster.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- [Ndb\\_config\\_from\\_host](#)

If the server is part of an NDB Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

If the server is not part of an NDB Cluster, then the value of this variable is an empty string.

- [Ndb\\_config\\_from\\_port](#)

If the server is part of an NDB Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- [Ndb\\_conflict\\_fn\\_max\\_del\\_win](#)

Shows the number of times that a row was rejected on the current SQL node due to NDB Cluster Replication conflict resolution using `NDB$MAX_DELETE_WIN()`, since the last time that this `mysqld` was started.

For more information, see [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- [Ndb\\_conflict\\_fn\\_max](#)

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.

For more information, see [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- [Ndb\\_conflict\\_fn\\_old](#)

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- [Ndb\\_conflict\\_fn\\_epoch](#)

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- [Ndb\\_conflict\\_fn\\_epoch2](#)

Shows the number of rows found to be in conflict in NDB Cluster Replication conflict resolution, when using `NDB$EPOCH2()`, on the source designated as the primary since the last time it was restarted.

For more information, see [NDB\\$EPOCH2\(\)](#).

- [Ndb\\_conflict\\_fn\\_epoch\\_trans](#)

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- [Ndb\\_conflict\\_fn\\_epoch2\\_trans](#)

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS2()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [NDB\\$EPOCH2\\_TRANS\(\)](#).

- [Ndb\\_conflict\\_last\\_conflict\\_epoch](#)

The most recent epoch in which a conflict was detected on this replica. You can compare this value with `Ndb_slave_max_replicated_epoch`; if `Ndb_slave_max_replicated_epoch` is greater than `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.

See [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- [Ndb\\_conflict\\_reflected\\_op\\_discard\\_count](#)

When using NDB Cluster Replication conflict resolution, this is the number of reflected operations that were not applied on the secondary, due to encountering an error during execution.

See [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- [Ndb\\_conflict\\_reflected\\_op\\_prepare\\_count](#)

When using conflict resolution with NDB Cluster Replication, this status variable contains the number of reflected operations that have been defined (that is, prepared for execution on the secondary).

See [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- [`Ndb\_conflict\_refresh\_op\_count`](#)

When using conflict resolution with NDB Cluster Replication, this gives the number of refresh operations that have been prepared for execution on the secondary.

See [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- [`Ndb\_conflict\_last\_stable\_epoch`](#)

Number of rows found to be in conflict by a transactional conflict function

See [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- [`Ndb\_conflict\_trans\_row\_conflict\_count`](#)

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given `mysqld` since the last time it was restarted.

Currently, the only transactional conflict detection function supported by NDB Cluster is `NDB$EPOCH_TRANS()`, so this status variable is effectively the same as `Ndb_conflict_fn_epoch_trans`.

For more information, see [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- [`Ndb\_conflict\_trans\_row\_reject\_count`](#)

Used in NDB Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only `Ndb_conflict_trans_row_conflict_count`, but any rows in or dependent on conflicting transactions.

For more information, see [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- [`Ndb\_conflict\_trans\_reject\_count`](#)

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

For more information, see [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- [`Ndb\_conflict\_trans\_detect\_iter\_count`](#)

Used in NDB Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to `Ndb_conflict_trans_conflict_commit_count`.

For more information, see [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- [`Ndb\_conflict\_trans\_conflict\_commit\_count`](#)

Used in NDB Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

For more information, see [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- [`Ndb\_epoch\_delete\_delete\_count`](#)

When using delete-delete conflict detection, this is the number of delete-delete conflicts detected, where a delete operation is applied, but the indicated row does not exist.

- [Ndb\\_execute\\_count](#)

Provides the number of round trips to the NDB kernel made by operations.

- [Ndb\\_last\\_commit\\_epoch\\_server](#)

The epoch most recently committed by NDB.

- [Ndb\\_last\\_commit\\_epoch\\_session](#)

The epoch most recently committed by this NDB client.

- [Ndb\\_number\\_of\\_data\\_nodes](#)

If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- [Ndb\\_pushed\\_queries\\_defined](#)

The total number of joins pushed down to the NDB kernel for distributed handling on the data nodes.

#### Note

Joins tested using EXPLAIN that can be pushed down contribute to this number.

- [Ndb\\_pushed\\_queries\\_dropped](#)

The number of joins that were pushed down to the NDB kernel but that could not be handled there.

- [Ndb\\_pushed\\_queries\\_executed](#)

The number of joins successfully pushed down to NDB and executed there.

- [Ndb\\_pushed\\_reads](#)

The number of rows returned to mysqld from the NDB kernel by joins that were pushed down.

#### Note

Executing EXPLAIN on joins that can be pushed down to NDB does not add to this number.

- [Ndb\\_pruned\\_scan\\_count](#)

This variable holds a count of the number of scans executed by NDBCLUSTER since the NDB Cluster was last started where NDBCLUSTER was able to use partition pruning.

Using this variable together with [Ndb\\_scan\\_count](#) can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.

- [Ndb\\_scan\\_count](#)

This variable holds a count of the total number of scans executed by NDBCLUSTER since the NDB Cluster was last started.

- [Ndb\\_slave\\_max\\_replicated\\_epoch](#)

The most recently committed epoch on this replica. You can compare this value with `Ndb_conflict_last_conflict_epoch`; if `Ndb_slave_max_replicated_epoch` is the greater of the two, no conflicts have yet been detected.

For more information, see [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_system_name`

If this MySQL Server is connected to an NDB cluster, this read-only variable shows the cluster system name. Otherwise, the value is an empty string.

### 21.3.3.10 NDB Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in an NDB Cluster. Normally it is not necessary to define TCP/IP connections; NDB Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

#### Note

For an exception to this rule, see [Section 21.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”](#).

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two NDB Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

#### Important

Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the NDB Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- `Checksum`

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | boolean       |
| Default            | false         |
| Range              | true, false   |
| Restart Type       | N (NDB 7.5.0) |

This parameter is a boolean parameter (enabled by setting it to `Y` or `1`, disabled by setting it to `N` or `0`). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- `Group`

When `ndb_optimized_node_selection` is enabled, node proximity is used in some cases to select which node to connect to. This parameter can be used to influence proximity by setting it to a lower value, which is interpreted as “closer”. See the description of the system variable for more information.

- [HostName1](#)

|                     |                    |
|---------------------|--------------------|
| Version (or later)  | NDB 7.5.0          |
| Type or units       | name or IP address |
| Default             | [...]              |
| Range               | ...                |
| <b>Restart Type</b> | N (NDB 7.5.0)      |

The [HostName1](#) and [HostName2](#) parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [HostName2](#)

|                     |                    |
|---------------------|--------------------|
| Version (or later)  | NDB 7.5.0          |
| Type or units       | name or IP address |
| Default             | [...]              |
| Range               | ...                |
| <b>Restart Type</b> | N (NDB 7.5.0)      |

The [HostName1](#) and [HostName2](#) parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [NodeId1](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | numeric       |
| Default             | [none]        |
| Range               | 1 - 255       |
| <b>Restart Type</b> | N (NDB 7.5.0) |

To identify a connection between two nodes it is necessary to provide their node IDs in the [\[tcp\]](#) section of the configuration file as the values of [NodeId1](#) and [NodeId2](#). These are the same unique [Id](#) values for each of these nodes as described in [Section 21.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- [NodeId2](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | numeric       |
| Default             | [none]        |
| Range               | 1 - 255       |
| <b>Restart Type</b> | N (NDB 7.5.0) |

To identify a connection between two nodes it is necessary to provide their node IDs in the [\[tcp\]](#) section of the configuration file as the values of [NodeId1](#) and [NodeId2](#). These are the same unique [Id](#) values for each of these nodes as described in [Section 21.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- [OverloadLimit](#)

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.5.0 |
|--------------------|-----------|

|               |                             |
|---------------|-----------------------------|
| Type or units | bytes                       |
| Default       | 0                           |
| Range         | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type  | N (NDB 7.5.0)               |

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See [Section 21.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#), for more information.

- [PortNumber \(OBSOLETE\)](#)

This parameter formerly specified the port number to be used for listening for connections from other nodes. It is now deprecated (and removed in NDB Cluster 7.5); use the [ServerPort](#) data node configuration parameter for this purpose instead (Bug #77405, Bug #21280456).

- [PreSendChecksum](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.6.6     |
| Type or units      | boolean       |
| Default            | false         |
| Range              | true, false   |
| Added              | NDB 7.6.6     |
| Restart Type       | N (NDB 7.5.0) |

If this parameter and [Checksum](#) are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors. Has no effect if [Checksum](#) is not also enabled.

- [ReceiveBufferMemory](#)

|                    |                               |
|--------------------|-------------------------------|
| Version (or later) | NDB 7.5.0                     |
| Type or units      | bytes                         |
| Default            | 2M                            |
| Range              | 16K - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                 |

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- [SendBufferMemory](#)

|                    |                                |
|--------------------|--------------------------------|
| Version (or later) | NDB 7.5.0                      |
| Type or units      | unsigned                       |
| Default            | 2M                             |
| Range              | 256K - 4294967039 (0xFFFFFEFF) |
| Restart Type       | N (NDB 7.5.0)                  |

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of

messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, [TotalSendBufferMemory](#)) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in NDB Cluster, see [Section 21.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#).

The default size of the send buffer is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- [SendSignalId](#)

|                    |                            |
|--------------------|----------------------------|
| Version (or later) | NDB 7.5.0                  |
| Type or units      | boolean                    |
| Default            | false (debug builds: true) |
| Range              | true, false                |
| Restart Type       | N (NDB 7.5.0)              |

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- [TcpBind\\_INADDR\\_ANY](#)

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- [TCP\\_MAXSEG\\_SIZE](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | unsigned      |
| Default            | 0             |
| Range              | 0 - 2G        |
| Restart Type       | N (NDB 7.5.0) |

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

- [TCP\\_RCV\\_BUF\\_SIZE](#)

|                    |               |
|--------------------|---------------|
| Version (or later) | NDB 7.5.0     |
| Type or units      | unsigned      |
| Default            | 0             |
| Range              | 0 - 2G        |
| Restart Type       | N (NDB 7.5.0) |

Determines the size of the receive buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- [TCP SND BUF SIZE](#)

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.5.0 |
|--------------------|-----------|

|               |               |
|---------------|---------------|
| Type or units | unsigned      |
| Default       | 0             |
| Range         | 0 - 2G        |
| Restart Type  | N (NDB 7.5.0) |

Determines the size of the send buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 21.19 NDB Cluster restart types**

| Symbol | Restart Type | Description                                                                                                                                  |
|--------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| N      | Node         | The parameter can be updated using a rolling restart (see <a href="#">Section 21.5.5, "Performing a Rolling Restart of an NDB Cluster"</a> ) |
| S      | System       | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter                                         |
| I      | Initial      | Data nodes must be restarted using the <code>--initial</code> option                                                                         |

### 21.3.3.11 NDB Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[tcp]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the `1.1.0.*` address range as shown:

```
Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency.

#### Note

To take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

### 21.3.3.12 NDB Cluster Shared Memory Connections

Communications between NDB cluster nodes are normally handled using TCP/IP. The shared memory (SHM) transporter is distinguished by the fact that signals are transmitted by writing in memory rather than on a socket. The shared-memory transporter (SHM) can improve performance by negating up to 20% of the overhead required by a TCP connection when running an API node (usually an SQL node) and a data node together on the same host. You can enable a shared memory connection in either of the two ways listed here:

- By setting the `UseShm` data node configuration parameter to 1, and setting `HostName` for the data node and `HostName` for the API node to the same value.
- By using `[shm]` sections in the cluster configuration file, each containing settings for `NodeId1` and `NodeId2`. This method is described in more detail later in this section.

Suppose a cluster is running a data node which has node ID 1 and an SQL node having node ID 51 on the same host computer at 10.0.0.1. To enable an SHM connection between these two nodes, all that is necessary is to insure that the following entries are included in the cluster configuration file:

```
[ndbd]
NodeId=1
HostName=10.0.0.1
UseShm=1

[mysqld]
NodeId=51
HostName=10.0.0.1
```

#### Important

The two entries just shown are in addition to any other entries and parameter settings needed by the cluster. A more complete example is shown later in this section.

Before starting data nodes that use SHM connections, it is also necessary to make sure that the operating system on each computer hosting such a data node has sufficient memory allocated to shared memory segments. See the documentation for your operating platform for information regarding this. In setups where multiple hosts are each running a data node and an API node, it is possible to enable shared memory on all such hosts by setting `UseShm` in the `[ndbd default]` section of the configuration file. This is shown in the example later in this section.

While not strictly required, tuning for all SHM connections in the cluster can be done by setting one or more of the following parameters in the `[shm default]` section of the cluster configuration (`config.ini`) file:

- `ShmSize`: Shared memory size
- `ShmSpinTime`: Time in  $\mu$ s to spin before sleeping
- `SendBufferMemory`: Size of buffer for signals sent from this node, in bytes.
- `SendSignalId`: Indicates that a signal ID is included in each signal sent through the transporter.

- **Checksum**: Indicates that a checksum is included in each signal sent through the transporter.
- **PreSendChecksum**: Checks of the checksum are made prior to sending the signal; Checksum must also be enabled for this to work

This example shows a simple setup with SHM connections defined on multiple hosts, in an NDB Cluster using 3 computers listed here by host name, hosting the node types shown:

1. **10.0.0.0**: The management server
2. **10.0.0.1**: A data node and an SQL node
3. **10.0.0.2**: A data node and an SQL node

In this scenario, each data node communicates with both the management server and the other data node using TCP transporters; each SQL node uses a shared memory transporter to communicate with the data nodes that is local to it, and a TCP transporter to communicate with the remote data node. A basic configuration reflecting this setup is enabled by the config.ini file whose contents are shown here:

```
[ndbd default]
DataDir=/path/to/datadir
UseShm=1

[shm default]
ShmSize=8M
ShmSpintime=200
SendBufferMemory=4M

[tcp default]
SendBufferMemory=8M

[ndb_mgmd]
NodeId=49
Hostname=10.0.0.0
DataDir=/path/to/datadir

[ndbd]
NodeId=1
Hostname=10.0.0.1
DataDir=/path/to/datadir

[ndbd]
NodeId=2
Hostname=10.0.0.2
DataDir=/path/to/datadir

[mysqld]
NodeId=51
Hostname=10.0.0.1

[mysqld]
NodeId=52
Hostname=10.0.0.2

[api]
[api]
```

Parameters affecting all shared memory transporters are set in the **[shm default]** section; these can be overridden on a per-connection basis in one or more **[shm]** sections. Each such section must be associated with a given SHM connection using **NodeId1** and **NodeId2**; the values required for these parameters are the node IDs of the two nodes connected by the transporter. You can also identify the nodes by host name using **HostName1** and **HostName2**, but these parameters are not required.

The API nodes for which no host names are set use the TCP transporter to communicate with data nodes independent of the hosts on which they are started; the parameters and values set in the **[tcp default]** section of the configuration file apply to all TCP transporters in the cluster.

For optimum performance, you can define a spin time for the SHM transporter ([ShmSpinTime](#) parameter); this affects both the data node receiver thread and the poll owner (receive thread or user thread) in [NDB](#).

- [Checksum](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | boolean       |
| Default             | true          |
| Range               | true, false   |
| <b>Restart Type</b> | N (NDB 7.5.0) |

This parameter is a boolean ([y/N](#)) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- [Group](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | unsigned      |
| Default             | 35            |
| Range               | 0 - 200       |
| <b>Restart Type</b> | N (NDB 7.5.0) |

Determines the group proximity; a smaller value is interpreted as being closer. The default value is sufficient for most conditions.

- [HostName1](#)

|                     |                    |
|---------------------|--------------------|
| Version (or later)  | NDB 7.5.0          |
| Type or units       | name or IP address |
| Default             | [...]              |
| Range               | ...                |
| <b>Restart Type</b> | N (NDB 7.5.0)      |

The [HostName1](#) and [HostName2](#) parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [HostName2](#)

|                     |                    |
|---------------------|--------------------|
| Version (or later)  | NDB 7.5.0          |
| Type or units       | name or IP address |
| Default             | [...]              |
| Range               | ...                |
| <b>Restart Type</b> | N (NDB 7.5.0)      |

The [HostName1](#) and [HostName2](#) parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [NodeId1](#)

|                              |               |
|------------------------------|---------------|
| Version (or later)           | NDB 7.5.0     |
| Type or units                | numeric       |
| Default                      | [none]        |
| Range                        | 1 - 255       |
| <a href="#">Restart Type</a> | N (NDB 7.5.0) |

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as [NodeId1](#) and [NodeId2](#).

- [NodeId2](#)

|                              |               |
|------------------------------|---------------|
| Version (or later)           | NDB 7.5.0     |
| Type or units                | numeric       |
| Default                      | [none]        |
| Range                        | 1 - 255       |
| <a href="#">Restart Type</a> | N (NDB 7.5.0) |

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as [NodeId1](#) and [NodeId2](#).

- [NodeIdServer](#)

|                              |               |
|------------------------------|---------------|
| Version (or later)           | NDB 7.5.0     |
| Type or units                | numeric       |
| Default                      | [none]        |
| Range                        | 1 - 63        |
| <a href="#">Restart Type</a> | N (NDB 7.5.0) |

Identify the server end of a shared memory connection. By default, this is the node ID of the data node.

- [OverloadLimit](#)

|                              |                             |
|------------------------------|-----------------------------|
| Version (or later)           | NDB 7.5.0                   |
| Type or units                | bytes                       |
| Default                      | 0                           |
| Range                        | 0 - 4294967039 (0xFFFFFEFF) |
| <a href="#">Restart Type</a> | N (NDB 7.5.0)               |

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See [Section 21.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#), and [Section 21.5.14.44, “The ndbinfo transporters Table”](#), for more information.

- [PreSendChecksum](#)

|                    |           |
|--------------------|-----------|
| Version (or later) | NDB 7.6.6 |
|--------------------|-----------|

|                     |               |
|---------------------|---------------|
| Type or units       | boolean       |
| Default             | false         |
| Range               | true, false   |
| Added               | NDB 7.6.6     |
| <b>Restart Type</b> | N (NDB 7.5.0) |

If this parameter and [Checksum](#) are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors. Has no effect if [Checksum](#) is not also enabled.

- [SendBufferMemory](#)

|                     |                                |
|---------------------|--------------------------------|
| Version (or later)  | NDB 7.6.6                      |
| Type or units       | integer                        |
| Default             | 2M                             |
| Range               | 256K - 4294967039 (0xFFFFFEFF) |
| Added               | NDB 7.6.6                      |
| <b>Restart Type</b> | N (NDB 7.5.0)                  |

Size (in bytes) of the shared memory buffer for signals sent from this node using a shared memory connection.

- [SendSignalId](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.5.0     |
| Type or units       | boolean       |
| Default             | false         |
| Range               | true, false   |
| <b>Restart Type</b> | N (NDB 7.5.0) |

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to [Y](#) causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in [-debug](#) builds.

- [ShmKey](#)

|                     |                             |
|---------------------|-----------------------------|
| Version (or later)  | NDB 7.5.0                   |
| Type or units       | unsigned                    |
| Default             | 0                           |
| Range               | 0 - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)               |

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value. If [UseShm](#) is enabled, the shared memory key is calculated automatically by [NDB](#).

- [ShmSize](#)

|                    |                               |
|--------------------|-------------------------------|
| Version (or later) | NDB 7.5.0                     |
| Type or units      | bytes                         |
| Default            | 1M                            |
| Range              | 64K - 4294967039 (0xFFFFFEFF) |

|                     |                               |
|---------------------|-------------------------------|
| Version (or later)  | NDB 7.6.6                     |
| Type or units       | bytes                         |
| Default             | 4M                            |
| Range               | 64K - 4294967039 (0xFFFFFEFF) |
| <b>Restart Type</b> | N (NDB 7.5.0)                 |

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by [ShmSize](#). The default value in NDB 7.6.6 and later is 4MB.

- [ShmSpinTime](#)

|                     |               |
|---------------------|---------------|
| Version (or later)  | NDB 7.6.6     |
| Type or units       | integer       |
| Default             | 0             |
| Range               | 0 - 2000      |
| Added               | NDB 7.6.6     |
| <b>Restart Type</b> | N (NDB 7.5.0) |

When receiving, the time to wait before sleeping, in microseconds.

- [SigNum](#)

|                     |                             |
|---------------------|-----------------------------|
| Version (or later)  | NDB 7.5.0                   |
| Type or units       | unsigned                    |
| Default             | [...]                       |
| Range               | 0 - 4294967039 (0xFFFFFEFF) |
| Deprecated          | NDB 7.6.6                   |
| <b>Restart Type</b> | N (NDB 7.5.0)               |

This parameter is no longer used as of NDB 7.6.6, and if set in that and later versions, is ignored.

The following applies only in NDB 7.6.5 and earlier:

When using the shared memory transporter, a process sends an operating system signal to the other process when there is new data available in the shared memory. Should that signal conflict with an existing signal, this parameter can be used to change it. This is a possibility when using SHM due to the fact that different operating systems use different signal numbers.

The default value of [SigNum](#) is 0; therefore, it must be set to avoid errors in the cluster log when using the shared memory transporter. Typically, this parameter is set to 10 in the [\[shm default\]](#) section of the [config.ini](#) file.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 21.20 NDB Cluster restart types**

| Symbol | Restart Type | Description                                                                                                                                  |
|--------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| N      | Node         | The parameter can be updated using a rolling restart (see <a href="#">Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”</a> ) |
| S      | System       | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter                                         |

| Symbol | Restart Type | Description                                                          |
|--------|--------------|----------------------------------------------------------------------|
| I      | Initial      | Data nodes must be restarted using the <code>--initial</code> option |

### 21.3.3.13 Configuring NDB Cluster Send Buffer Parameters

The `NDB` kernel employs a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can be accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of NDB Cluster nodes—that is, it can be set in the `[ndbd]`, `[mgt]`, and `[api]` (or `[mysql]`) sections of the `config.ini` file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

**Table 21.21 Transporter types with maximum send buffer sizes**

| Transporter | Maximum Send Buffer Size (bytes)             |
|-------------|----------------------------------------------|
| TCP         | <code>SendBufferMemory</code> (default = 2M) |
| SHM         | 20K                                          |

This enables existing configurations to function in close to the same way as they did with NDB Cluster 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (`Send Buffers overloaded in NDB kernel`) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.
- **SendBufferMemory.** This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory`. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.
- **ReservedSendBufferMemory.** Removed in NDB 7.5.2.

|                    |                             |
|--------------------|-----------------------------|
| Version (or later) | NDB 7.5.0                   |
| Type or units      | bytes                       |
| Default            | 256K                        |
| Range              | 0 - 4294967039 (0xFFFFFEFF) |
| Removed            | NDB 7.5.2                   |
| Restart Type       | N (NDB 7.5.0)               |

Prior to NDB 7.5.2, this data node parameter was present, but was not actually used (Bug #77404, Bug #21280428).

You can use the `ndbinfo.transporters` table to monitor send buffer memory usage, and to detect slowdown and overload conditions that can adversely affect performance.

### 21.3.4 Using High-Speed Interconnects with NDB Cluster

Even before design of `NDBCLUSTER` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDBCLUSTER` was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The NDB Cluster codebase provides for four different transporters:

- *TCP/IP using 100 Mbps or gigabit Ethernet*, as discussed in [Section 21.3.3.10, “NDB Cluster TCP/IP Connections”](#).
- *Direct (machine-to-machine) TCP/IP*; although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for NDB Cluster. See [Section 21.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”](#), for details.
- *Shared memory (SHM)*. Supported in production beginning with NDB 7.6.6. For more information about SHM, see [Section 21.3.3.12, “NDB Cluster Shared Memory Connections”](#).
- *Scalable Coherent Interface (SCI)*.

#### Note

Using SCI transporters in NDB Cluster requires specialized hardware, software, and MySQL binaries not available using an NDB 7.5 or 7.6 distributions.

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with NDB Cluster.

Regardless of the transporter used, `NDB` attempts to make sure that communication with data node processes is done using chunks that are as large as possible since this benefits all types of data transmission.

## 21.4 NDB Cluster Programs

Using and managing an NDB Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in an NDB Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the NDB Cluster data, management, and SQL node processes (`ndbd`, `ndbmttd`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

Information about the program `ndb_setup.py`, used to start the NDB Cluster Auto-Installer (now deprecated), is also included in this section. You should be aware that [Section 21.4.27, “`ndb\_setup.py` — Start browser-based Auto-Installer for NDB Cluster \(DEPRECATED\)”](#), contains information about the command-line client only; for information about using the GUI installer spawned by this program to configure and deploy an NDB Cluster, see [Section 21.2.8, “The NDB Cluster Auto-Installer \(NDB 7.5\) \(No longer supported\)”](#).

For information about using `mysqld` as an NDB Cluster process, see [Section 21.5.9, “MySQL Server Usage for NDB Cluster”](#).

Other `NDB` utility, diagnostic, and example programs are included with the NDB Cluster distribution. These include `ndb_restore`, `ndb_show_tables`, and `ndb_config`. These programs are also covered in this section.

The final portion of this section contains tables of options that are common to all the various NDB Cluster programs.

### 21.4.1 ndbd — The NDB Cluster Data Node Daemon

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In an NDB Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

Options that can be used with `ndbd` are shown in the following table. Additional descriptions follow the table.

**Table 21.22 Command-line options used with the program `ndbd`**

| Format                                           | Description                                                                                                    | Added, Deprecated, or Removed                      |
|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--bind-address=name</code>                 | Local bind address                                                                                             | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--character-sets-dir=path</code>           | Directory containing character sets                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-delay=#</code>                   | Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retries=#</code>                 | Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries)        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retry-delay=#</code>             | Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-string=connection-string,</code> | Same as <code>--ndb-connectstring</code>                                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                  |                                                                                                                |                                                    |
| <code>--core-file</code>                         | Write core file on error; used in debugging                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--daemon,</code>                           | Start <code>ndbd</code> as daemon (default); override with <code>--nodaemon</code>                             | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-d</code>                                  |                                                                                                                |                                                    |
| <code>--defaults-extra-file=path</code>          | Read given file after global files are read                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-file=path</code>                | Read default options from given file only                                                                      | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-group-suffix=string</code>      | Also read groups with <code>concat(group, suffix)</code>                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--foreground</code>                        | Run <code>ndbd</code> in foreground, provided for debugging purposes (implies <code>--nodaemon</code> )        | (Supported in all NDB releases based on MySQL 5.7) |

| Format                                       | Description                                                                                                                                              | Added, Deprecated, or Removed                      |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --help,<br>-?                                | Display help text and exit                                                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| --initial                                    | Perform initial start of ndbd, including file system cleanup; consult documentation before using this option                                             | (Supported in all NDB releases based on MySQL 5.7) |
| --initial-start                              | Perform partial initial start (requires --nowait-nodes)                                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| --install[=name]                             | Used to install data node process as Windows service; does not apply on other platforms                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| --logbuffer-size=#                           | Control size of log buffer; for use when debugging with many log messages being generated; default is sufficient for normal operations                   | ADDED: NDB 7.6.6                                   |
| --login-path=path                            | Read given path from login file                                                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-connectstring=connection-string,<br>-c | Set connect string for connecting to ndb_mgmd.<br>Syntax: "[nodeid=id;]<br>[host=]hostname[:port]".<br>Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-mgmd-host=connection-string,<br>-c     | Same as --ndb-connectstring                                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-nodeid=#                               | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| --nodaemon                                   | Do not start ndbd as daemon; provided for testing purposes                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| --no-defaults                                | Do not read default options from any option file other than login file                                                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| --nostart,<br>-n                             | Do not start ndbd immediately; ndbd waits for command to start from ndb_mgm                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --nowait-nodes=list                          | Do not wait for these data nodes to start (takes comma-separated list of node IDs); requires --ndb-nodeid                                                | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-optimized-node-selection               | Enable optimizations for selection of nodes for transactions.<br>Enabled by default; use --skip-ndb-optimized-node-selection to disable                  | (Supported in all NDB releases based on MySQL 5.7) |
| --print-defaults                             | Print program argument list and exit                                                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |

| Format             | Description                                                                                                          | Added, Deprecated, or Removed                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --remove [ =name ] | Used to remove data node process that was previously installed as Windows service; does not apply on other platforms | (Supported in all NDB releases based on MySQL 5.7) |
| --usage,<br>-?     | Display help text and exit; same as --help                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --verbose,<br>-v   | Write extra debugging information to node log                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| --version,<br>-V   | Display version information and exit                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |

**Note**

All of these options also apply to the multithreaded version of this program (`ndbmtd`) and you may substitute “`ndbmtd`” for “`ndbd`” wherever the latter occurs in this section.

- `--bind-address`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--bind-address=name</code> |
| Type                | String                           |
| Default Value       |                                  |

Causes `ndbd` to bind to a specific network interface (host name or IP address). This option has no default value.

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- `--connect-delay=`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--connect-delay=#</code> |
| Deprecated          | Yes                            |
| Type                | Numeric                        |
| Default Value       | 5                              |
| Minimum Value       | 0                              |
| Maximum Value       | 3600                           |

Determines the time to wait between attempts to contact a management server when starting (the number of attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

This option is deprecated, and is subject to removal in a future release of NDB Cluster. Use `--connect-retry-delay` instead.

- `--connect-retries=`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
|---------------------|----------------------------------|

|               |         |
|---------------|---------|
| Type          | Numeric |
| Default Value | 12      |
| Minimum Value | 0       |
| Maximum Value | 65535   |

Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries). The default is 12 attempts. The time to wait between attempts is controlled by the `--connect-retry-delay` option.

- `--connect-retry-delay=#`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Numeric                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 4294967295                           |

Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

This option takes the place of the `--connect-delay` option, which is now deprecated and subject to removal in a future release of NDB Cluster.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | [none]                                          |

Same as `--ndb-connectstring`.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--daemon, -d`

|                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>--daemon</code> |
| Type                | Boolean               |
| Default Value       | TRUE                  |

Instructs `ndbd` or `ndbmttd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

This option has no effect when running `ndbd` or `ndbmttd` on Windows platforms.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |

|               |                     |
|---------------|---------------------|
| Default Value | <code>[none]</code> |
|---------------|---------------------|

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | <code>[none]</code>               |

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | <code>[none]</code>                         |

Also read groups with concat(group, suffix).

- `--foreground`

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>--foreground</code> |
| Type                | Boolean                   |
| Default Value       | <code>FALSE</code>        |

Causes `ndbd` or `ndbmttd` to execute as a foreground process, primarily for debugging purposes. This option implies the `--nodaemon` option.

This option has no effect when running `ndbd` or `ndbmttd` on Windows platforms.

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--initial`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--initial</code> |
| Type                | Boolean                |

|               |                    |
|---------------|--------------------|
| Default Value | <code>FALSE</code> |
|---------------|--------------------|

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. On some operating systems, this process can take a substantial amount of time.

An `--initial` start is to be used *only* when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the NDB Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

### Warning

To avoid the possibility of eventual data loss, it is recommended that you *not* use the `--initial` option together with `StopOnError = 0`. Instead, set `StopOnError` to 0 in `config.ini` only after the cluster has been started, then restart the data nodes normally—that is, without the `--initial` option. See the description of the `StopOnError` parameter for a detailed explanation of this issue. (Bug #24945638)

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

### Important

This option does *not* affect either of the following types of files:

- Backup files that have already been created by the affected node
- NDB Cluster Disk Data files (see [Section 21.5.10, “NDB Cluster Disk Data Tables”](#)).

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running. This recovery of data occurs automatically, and requires no user intervention in an NDB Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- `--initial-start`

|                     |                              |
|---------------------|------------------------------|
| Command-Line Format | <code>--initial-start</code> |
| Type                | Boolean                      |
| Default Value       | <code>FALSE</code>           |

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
shell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
```

```
shell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.

### Important

Do not confuse this option with the `--nowait-nodes` option for `ndb_mgmd`, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

- `--install[=name]`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--install[=name]</code> |
| Platform Specific   | Windows                       |
| Type                | String                        |
| Default Value       | <code>ndbd</code>             |

Causes `ndbd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndbd`. Although it is preferable to specify other `ndbd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other `ndbd` options that affect the starting of data nodes—including `--initial-start`, `--nostart`, and `--nowait-nodes`—together with `--install`, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--logbuffer-size=#`

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | <code>--logbuffer-size=#</code> |
| Introduced          | 5.7.22-ndb-7.6.6                |
| Type                | Integer                         |
| Default Value       | <code>32768</code>              |
| Minimum Value       | <code>2048</code>               |
| Maximum Value       | <code>4294967295</code>         |

Sets the size of the data node log buffer. When debugging with high amounts of extra logging, it is possible for the log buffer to run out of space if there are too many log messages, in which case some log messages can be lost. This should not occur during normal operations.

- `--login-path`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type                | String                         |
| Default Value       | <code>[none]</code>            |

Read given path from login file.

- [--ndb-connectstring](#)

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |
| Default Value       | [none]                                             |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- [--ndb-mgmd-host](#)

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | [none]                                         |

Same as [--ndb-connectstring](#).

- [--ndb-nodeid](#)

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | [none]                      |

Set node ID for this node, overriding any ID set by [--ndb-connectstring](#).

- [--ndb-optimized-node-selection](#)

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use [--skip-ndb-optimized-node-selection](#) to disable.

- [--nodaemon](#)

|                     |                         |
|---------------------|-------------------------|
| Command-Line Format | <code>--nodaemon</code> |
| Type                | Boolean                 |
| Default Value       | FALSE                   |

Prevents `ndbd` or `ndbmttd` from executing as a daemon process. This option overrides the [--daemon](#) option. This is useful for redirecting output to the screen when debugging the binary.

The default behavior for `ndbd` and `ndbmttd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect.

- [--no-defaults](#)

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- [--nostart, -n](#)

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--nostart</code> |
| Type                | Boolean                |

|               |                    |
|---------------|--------------------|
| Default Value | <code>FALSE</code> |
|---------------|--------------------|

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see [Section 21.5.1, “Commands in the NDB Cluster Management Client”](#)).

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--nowait-nodes=list</code> |
| Type                | String                           |
| Default Value       |                                  |

This option takes a list of data nodes which for which the cluster does not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does *not* wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster starts as soon as nodes 2, 4, and 5 connect and does not wait for node 3 to start.

- `--print-defaults`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--remove[=name]`

|                     |                              |
|---------------------|------------------------------|
| Command-Line Format | <code>--remove[=name]</code> |
| Platform Specific   | Windows                      |
| Type                | String                       |
| Default Value       | <code>ndbd</code>            |

Causes an `ndbd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndbd`.

The `--remove` option has no effect on non-Windows platforms.

- `--usage`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--verbose, -v`

Causes extra debug output to be written to the node log.

In NDB 7.6.4 and later, you can also use `NODELOG DEBUG ON` and `NODELOG DEBUG OFF` to enable and disable this extra logging while the data node is running.

- `--version`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file.

These log files are listed below. `node_id` is and represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is `2`.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtpupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
EOM
```

Listings of possible `ndbd` exit codes and messages generated when a data node process shuts down prematurely can be found in [Data Node Error Messages](#).

### Important

*The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are not listed in chronological order; rather, they correspond to the order of the trace files as determined in the `ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.*

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the NDB Cluster development team.

It is possible to configure the number of these trace files that are created before old files are overwritten. `trace_id` is a number which is incremented for each successive trace file.

- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.
- `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.
- `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.
- `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See [Section 21.3.3.3, “NDB Cluster Connection Strings”](#), for additional information about this issue. For more information about data node configuration parameters, see [Section 21.3.3.6, “Defining NDB Cluster Data Nodes”](#).

When `ndbd` starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` using the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a multi-processor system performing a large number of operations (including updates), the `ndbd` process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several `ndbd` processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 5.7 in a production setting. See [Section 21.1.7, “Known Limitations of NDB Cluster”](#).

## 21.4.2 ndbinfo\_select\_all — Select From ndbinfo Tables

`ndbinfo_select_all` is a client program that selects all rows and columns from one or more tables in the `ndbinfo` database

Not all `ndbinfo` tables available in the `mysql` client can be read by this program. In addition, `ndbinfo_select_all` can show information about some tables internal to `ndbinfo` which cannot be accessed using SQL, including the `tables` and `columns` metadata tables.

To select from one or more `ndbinfo` tables using `ndbinfo_select_all`, it is necessary to supply the names of the tables when invoking the program as shown here:

```
shell> ndbinfo_select_all table_name1 [table_name2] [...]
```

For example:

```
shell> ndbinfo_select_all logbuffers logspaces
== logbuffers ==
node_id log_type log_id log_part total used high
 5 0 0 33554432 262144 0
 6 0 0 33554432 262144 0
 7 0 0 33554432 262144 0
 8 0 0 33554432 262144 0
== logspaces ==
node_id log_type log_id log_part total used high
 5 0 0 268435456 0 0
 5 0 0 268435456 0 0
 5 0 0 268435456 0 0
 5 0 0 268435456 0 0
 6 0 0 268435456 0 0
 6 0 0 268435456 0 0
 6 0 0 268435456 0 0
 6 0 0 268435456 0 0
 7 0 0 268435456 0 0
 7 0 0 268435456 0 0
 7 0 0 268435456 0 0
 7 0 0 268435456 0 0
 8 0 0 268435456 0 0
 8 0 0 268435456 0 0
 8 0 0 268435456 0 0
 8 0 0 268435456 0 0
shell>
```

Options that can be used with `ndbinfo_select_all` are shown in the following table. Additional descriptions follow the table.

**Table 21.23 Command-line options used with the program `ndbinfo_select_all`**

| Format                                              | Description                                                                                                                                                                                | Added, Deprecated, or Removed                      |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--character-sets-dir=path</code>              | Directory containing character sets                                                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retries=#</code>                    | Number of times to retry connection before giving up                                                                                                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retry-delay=#</code>                | Number of seconds to wait between attempts to contact management server                                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-string=connection-string,</code>    | Same as <code>--ndb-connectstring</code>                                                                                                                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     |                                                                                                                                                                                            |                                                    |
| <code>--core-file</code>                            | Write core file on error; used in debugging                                                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--database=db_name,</code>                    | Name of database where table is located                                                                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-d</code>                                     |                                                                                                                                                                                            |                                                    |
| <code>--defaults-extra-file=path</code>             | Read given file after global files are read                                                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-file=path</code>                   | Read default options from given file only                                                                                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-group-suffix=string</code>         | Also read groups with concat(group, suffix)                                                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--delay=#</code>                              | Set delay in seconds between loops                                                                                                                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--help,</code>                                | Display help text and exit                                                                                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-?</code>                                     |                                                                                                                                                                                            |                                                    |
| <code>--login-path=path</code>                      | Read given path from login file                                                                                                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--loops=#,</code>                             | Set number of times to perform select                                                                                                                                                      | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-l</code>                                     |                                                                                                                                                                                            |                                                    |
| <code>--ndb-connectstring=connection-string,</code> | Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: "[nodeid=id;]<br>[host=]hostname[:port]". Overrides entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code> | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     |                                                                                                                                                                                            |                                                    |
| <code>--ndb-mgmd-host=connection-string,</code>     | Same as <code>--ndb-connectstring</code>                                                                                                                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     |                                                                                                                                                                                            |                                                    |
| <code>--ndb-nodeid=#</code>                         | Set node ID for this node, overriding any ID set by <code>--ndb-connectstring</code>                                                                                                       | (Supported in all NDB releases based on MySQL 5.7) |

| Format                         | Description                                                                                                                             | Added, Deprecated, or Removed                      |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --no-defaults                  | Do not read default options from any option file other than login file                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-optimized-node-selection | Enable optimizations for selection of nodes for transactions.<br>Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.7) |
| --parallelism=#, -p            | Set degree of parallelism                                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| --print-defaults               | Print program argument list and exit                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| --usage, -?                    | Display help text and exit; same as --help                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --version, -V                  | Display version information and exit                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | 12                               |
| Minimum Value       | 0                                |
| Maximum Value       | 12                               |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 5                                    |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |

|               |        |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

Same as `--ndb-connectstring`.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
|---------------------|-----------------------------------------|

|      |        |
|------|--------|
| Type | String |
|------|--------|

|               |        |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
|---------------------|-----------------------------------|

|      |        |
|------|--------|
| Type | String |
|------|--------|

|               |        |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
|---------------------|---------------------------------------------|

|      |        |
|------|--------|
| Type | String |
|------|--------|

|               |        |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

Also read groups with concat(group, suffix).

- `--delay=seconds`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--delay=#</code> |
|---------------------|------------------------|

|      |         |
|------|---------|
| Type | Numeric |
|------|---------|

|               |   |
|---------------|---|
| Default Value | 5 |
|---------------|---|

|               |   |
|---------------|---|
| Minimum Value | 0 |
|---------------|---|

|               |         |
|---------------|---------|
| Maximum Value | MAX_INT |
|---------------|---------|

This option sets the number of seconds to wait between executing loops. Has no effect if `--loops` is set to 0 or 1.

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
|---------------------|--------------------------------|

|      |        |
|------|--------|
| Type | String |
|------|--------|

|               |        |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

Read given path from login file.

- `--loops=number, -l number`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--loops=#</code> |
| Type                | Numeric                |
| Default Value       | 1                      |
| Minimum Value       | 0                      |
| Maximum Value       | <code>MAX_INT</code>   |

This option sets the number of times to execute the select. Use `--delay` to set the time between loops.

- `--ndb-connectstring`

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |
| Default Value       | [none]                                             |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | [none]                                         |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | [none]                      |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- [--usage](#)

|                     |                         |
|---------------------|-------------------------|
| Command-Line Format | <a href="#">--usage</a> |
|---------------------|-------------------------|

Display help text and exit; same as [--help](#).

- [--version](#)

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <a href="#">--version</a> |
|---------------------|---------------------------|

Display version information and exit.

### 21.4.3 ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)

`ndbmtd` is a multithreaded version of `ndbd`, the process that is used to handle all the data in tables using the `NDBCLUSTER` storage engine. `ndbmtd` is intended for use on host computers having multiple CPU cores. Except where otherwise noted, `ndbmtd` functions in the same way as `ndbd`; therefore, in this section, we concentrate on the ways in which `ndbmtd` differs from `ndbd`, and you should consult [Section 21.4.1, “ndbd — The NDB Cluster Data Node Daemon”](#), for additional information about running NDB Cluster data nodes that apply to both the single-threaded and multithreaded versions of the data node process.

Command-line options and configuration parameters used with `ndbd` also apply to `ndbmtd`. For more information about these options and parameters, see [Section 21.4.1, “ndbd — The NDB Cluster Data Node Daemon”](#), and [Section 21.3.3.6, “Defining NDB Cluster Data Nodes”](#), respectively.

`ndbmtd` is also file system-compatible with `ndbd`. In other words, a data node running `ndbd` can be stopped, the binary replaced with `ndbmtd`, and then restarted without any loss of data. (However, when doing this, you must make sure that `MaxNoOfExecutionThreads` is set to an appropriate value before restarting the node if you wish for `ndbmtd` to run in multithreaded fashion.) Similarly, an `ndbmtd` binary can be replaced with `ndbd` simply by stopping the node and then starting `ndbd` in place of the multithreaded binary. It is not necessary when switching between the two to start the data node binary using [--initial](#).

Using `ndbmtd` differs from using `ndbd` in two key respects:

1. Because `ndbmtd` runs by default in single-threaded mode (that is, it behaves like `ndbd`), you must configure it to use multiple threads. This can be done by setting an appropriate value in the `config.ini` file for the `MaxNoOfExecutionThreads` configuration parameter or the `ThreadConfig` configuration parameter. Using `MaxNoOfExecutionThreads` is simpler, but `ThreadConfig` offers more flexibility. For more information about these configuration parameters and their use, see [Multi-Threading Configuration Parameters \(ndbmtd\)](#).
2. Trace files are generated by critical errors in `ndbmtd` processes in a somewhat different fashion from how these are generated by `ndbd` failures. These differences are discussed in more detail in the next few paragraphs.

Like `ndbd`, `ndbmtd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by `ndbd`.

In the event of a critical error, `ndbmtd` generates trace files describing what happened just prior to the error's occurrence. These files, which can be found in the data node's `DataDir`, are useful for analysis of problems by the NDB Cluster Development and Support teams. One trace file is generated for each `ndbmtd` thread. The names of these files have the following pattern:

|                                                          |
|----------------------------------------------------------|
| <code>ndb_node_id_trace.log.trace_id_tthread_id</code> , |
|----------------------------------------------------------|

In this pattern, `node_id` stands for the data node's unique node ID in the cluster, `trace_id` is a trace sequence number, and `thread_id` is the thread ID. For example, in the event of the failure of an `ndbmttd` process running as an NDB Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node's data directory. If this is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.

The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmttd`. See [Data Node Error Messages](#), for a listing of these.

#### Note

It is possible to use `ndbd` and `ndbmttd` concurrently on different data nodes in the same NDB Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

### 21.4.4 ndb\_mgmd — The NDB Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

Options that can be used with `ndb_mgmd` are shown in the following table. Additional descriptions follow the table.

**Table 21.24 Command-line options used with the program `ndb_mgmd`**

| Format                                                     | Description                                                                                                                                 | Added, Deprecated, or Removed                      |
|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--bind-address=host</code>                           | Local bind address                                                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--character-sets-dir=path</code>                     | Directory containing character sets                                                                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--config-cache[=TRUE FALSE]</code>                   | Enable management server configuration cache; true by default                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--config-file=file, -f</code>                        | Specify cluster configuration file; also specify <code>--reload</code> or <code>--initial</code> to override configuration cache if present | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--configdir=directory, --config-dir=directory</code> | Specify cluster management server configuration cache directory                                                                             | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retries=#</code>                           | Number of times to retry connection before giving up                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retry-delay=#</code>                       | Number of seconds to wait between attempts to contact management server                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-string=connection-string, -c</code>        | Same as <code>--ndb-connectstring</code>                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--core-file</code>                                   | Write core file on error; used in debugging                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |

| <b>Format</b>                                | <b>Description</b>                                                                                                                                       | <b>Added, Deprecated, or Removed</b>               |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --daemon,<br>-d                              | Run ndb_mgmd in daemon mode (default)                                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-extra-file=path                   | Read given file after global files are read                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-file=path                         | Read default options from given file only                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-group-suffix=string               | Also read groups with concat(group, suffix)                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --help,                                      | Display help text and exit                                                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| -?                                           |                                                                                                                                                          |                                                    |
| --initial                                    | Causes management server to reload configuration data from configuration file, bypassing configuration cache                                             | (Supported in all NDB releases based on MySQL 5.7) |
| --install[=name]                             | Used to install management server process as Windows service; does not apply on other platforms                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| --interactive                                | Run ndb_mgmd in interactive mode (not officially supported in production; for testing purposes only)                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --log-name=name                              | Name to use when writing cluster log messages applying to this node                                                                                      | (Supported in all NDB releases based on MySQL 5.7) |
| --login-path=path                            | Read given path from login file                                                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| --mycnf                                      | Read cluster configuration data from my.cnf file                                                                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-connectstring=connection-string,<br>-c | Set connect string for connecting to ndb_mgmd.<br>Syntax: "[nodeid=id;]<br>[host=]hostname[:port]".<br>Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-mgmd-host=connection-string,<br>-c     | Same as --ndb-connectstring                                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-nodeid=#                               | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-optimized-node-selection               | Enable optimizations for selection of nodes for transactions.<br>Enabled by default; use --skip-ndb-optimized-node-selection to disable                  | (Supported in all NDB releases based on MySQL 5.7) |

| Format               | Description                                                                                                                                                                       | Added, Deprecated, or Removed                      |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --no-defaults        | Do not read default options from any option file other than login file                                                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| --no-nodeid-checks   | Do not provide any node ID checks                                                                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| --nodaemon           | Do not run ndb_mgmd as a daemon                                                                                                                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| --nowait-nodes=list  | Do not wait for management nodes specified when starting this management server; requires --ndb-nodeid option                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --print-defaults     | Print program argument list and exit                                                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --print-full-config, | Print full configuration and exit                                                                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| -P                   |                                                                                                                                                                                   |                                                    |
| --reload             | Causes management server to compare configuration file with configuration cache                                                                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| --remove[=name]      | Used to remove management server process that was previously installed as Windows service, optionally specifying name of service to be removed; does not apply on other platforms | (Supported in all NDB releases based on MySQL 5.7) |
| --usage,             | Display help text and exit; same as --help                                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| -?                   |                                                                                                                                                                                   |                                                    |
| --skip-config-file   | Do not use configuration file                                                                                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --verbose,           | Write additional information to log                                                                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| -v                   |                                                                                                                                                                                   |                                                    |
| --version,           | Display version information and exit                                                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| -V                   |                                                                                                                                                                                   |                                                    |

- `--bind-address=host`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--bind-address=host</code> |
| Type                | String                           |
| Default Value       | [none]                           |

Causes the management server to bind to a specific network interface (host name or IP address). This option has no default value.

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- `--config-cache`

|                     |                                              |
|---------------------|----------------------------------------------|
| Command-Line Format | <code>--config-cache[ =TRUE   FALSE ]</code> |
| Type                | Boolean                                      |
| Default Value       | <code>TRUE</code>                            |

This option, whose default value is `1` (or `TRUE`, or `ON`), can be used to disable the management server's configuration cache, so that it reads its configuration from `config.ini` every time it starts (see [Section 21.3.3, “NDB Cluster Configuration Files”](#)). You can do this by starting the `ndb_mgmd` process with any one of the following options:

- `--config-cache=0`
- `--config-cache=FALSE`
- `--config-cache=OFF`
- `--skip-config-cache`

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the `--config-cache` option or the `--skip-config-cache` option is ignored. Therefore, to disable configuration caching, the option should be used the *first* time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has *already* created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with `--skip-config-cache` (or with `--config-cache` set equal to `0`, `OFF`, or `FALSE`).

Configuration cache files are normally created in a directory named `mysql-cluster` under the installation directory (unless this location has been overridden using the `--configdir` option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

`node-id` is the management server's node ID; `seq-number` is a sequence number, beginning with `1`. For example, if the management server's node ID is `5`, then the first three configuration cache files would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` or `--initial` instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.

`ndb_mgmd` does not check for the configuration directory (`--configdir`) or attempts to create one when `--skip-config-cache` is used. (Bug #13428853)

- `--config-file=filename, -f filename`

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | <code>--config-file=file</code> |
| Disabled by         | <code>skip-config-file</code>   |
| Type                | File name                       |

|               |        |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

This option has no default value, and is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache.

The `--config-file` option is also read if `ndb_mgmd` was started with `--config-cache=OFF`. See [Section 21.3.3, “NDB Cluster Configuration Files”](#), for more information.

- `--configdir=dir_name`

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| Command-Line Format | <code>--configdir=directory</code><br><code>--config-dir=directory</code> |
| Type                | File name                                                                 |
| Default Value       | <code>\$INSTALLDIR/mysql-cluster</code>                                   |

Specifies the cluster management server's configuration cache directory. `--config-dir` is an alias for this option.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | 12                               |
| Minimum Value       | 0                                |
| Maximum Value       | 12                               |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 5                                    |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | [none]                                          |

Same as `--ndb-connectstring`.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--daemon, -d`

|                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>--daemon</code> |
| Type                | Boolean               |
| Default Value       | <code>TRUE</code>     |

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

This option has no effect when running `ndb_mgmd` on Windows platforms.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | <code>[none]</code>                     |

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | <code>[none]</code>               |

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | <code>[none]</code>                         |

Also read groups with concat(group, suffix).

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--initial`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--initial</code> |
| Type                | Boolean                |
| Default Value       | <code>FALSE</code>     |

Configuration data is cached internally, rather than being read from the cluster global configuration file each time the management server is started (see [Section 21.3.3, “NDB Cluster Configuration Files”](#)). Using the `--initial` option overrides this behavior, by forcing the management server

to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the `--reload` option. First, `--reload` forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, `--reload` does not delete any existing cache files.

If `ndb_mgmd` is invoked with `--initial` but cannot find a global configuration file, the management server cannot start.

When a management server starts, it checks for another management server in the same NDB Cluster and tries to use the other management server's configuration data. This behavior has implications when performing a rolling restart of an NDB Cluster with multiple management nodes. See [Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”](#), for more information.

When used together with the `--config-file` option, the cache is cleared only if the configuration file is actually found.

- `--install[=name]`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--install[=name]</code> |
| Platform Specific   | Windows                       |
| Type                | String                        |
| Default Value       | <code>ndb_mgmd</code>         |

Causes `ndb_mgmd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndb_mgmd`. Although it is preferable to specify other `ndb_mgmd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use them together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other `ndb_mgmd` options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--interactive`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--interactive</code> |
| Type                | Boolean                    |
| Default Value       | <code>FALSE</code>         |

Starts `ndb_mgmd` in interactive mode; that is, an `ndb_mgm` client session is started as soon as the management server is running. This option does not start any other NDB Cluster nodes.

- `--login-path`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type                | String                         |
| Default Value       | <code>[none]</code>            |

Read given path from login file.

- `--log-name=name`

|                     |                              |
|---------------------|------------------------------|
| Command-Line Format | <code>--log-name=name</code> |
| Type                | String                       |
| Default Value       | <code>MgmtSrvr</code>        |

Provides a name to be used for this node in the cluster log.

- `--mycnf`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--mycnf</code> |
| Type                | Boolean              |
| Default Value       | <code>FALSE</code>   |

Read configuration data from the `my.cnf` file.

- `--ndb-connectstring`

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |
| Default Value       | <code>[none]</code>                                |

Set connection string. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`, ignored if `--config-file` is specified.

- `--ndb-mgmd-host`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | <code>[none]</code>                            |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | <code>[none]</code>         |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

- [--no-nodeid-checks](#)

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | <code>--no-nodeid-checks</code> |
| Type                | Boolean                         |
| Default Value       | <code>FALSE</code>              |

Do not perform any checks of node IDs.

- [--nodaemon](#)

|                     |                         |
|---------------------|-------------------------|
| Command-Line Format | <code>--nodaemon</code> |
| Type                | Boolean                 |
| Default Value       | <code>FALSE</code>      |

Instructs `ndb_mgmd` not to start as a daemon process.

The default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms.

- [--nowait-nodes](#)

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--nowait-nodes=list</code> |
| Type                | Numeric                          |
| Default Value       | <code>[none]</code>              |
| Minimum Value       | <code>1</code>                   |
| Maximum Value       | <code>255</code>                 |

When starting an NDB Cluster is configured with two management nodes, each management server normally checks to see whether the other `ndb_mgmd` is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other `ndb_mgmd` to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a `config.ini` file (where we have omitted most of the configuration parameters that are not relevant to this example):

```
[ndbd]
NodeId = 1
HostName = 198.51.100.101

[ndbd]
NodeId = 2
HostName = 198.51.100.102

[ndbd]
NodeId = 3
HostName = 198.51.100.103

[ndbd]
NodeId = 4
HostName = 198.51.100.104

[ndb_mgmd]
NodeId = 10
HostName = 198.51.100.150

[ndb_mgmd]
NodeId = 11
```

```
HostName = 198.51.100.151
[api]
NodeId = 20
HostName = 198.51.100.200
[api]
NodeId = 21
HostName = 198.51.100.201
```

Assume that you wish to start this cluster using only the management server having node ID [10](#) and running on the host having the IP address 198.51.100.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 198.51.100.150 to enter the following command:

```
shell> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using [--nowait-nodes](#), you must also use the [--ndb-nodeid](#) option to specify the node ID of this [ndb\\_mgmd](#) process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

```
shell> ndbd -c 198.51.100.150,198.51.100.151
```

The same is true with regard to the connection string used with any [mysqld](#) processes that you wish to start as NDB Cluster SQL nodes connected to this cluster. See [Section 21.3.3.3, “NDB Cluster Connection Strings”](#), for more information.

When used with [ndb\\_mgmd](#), this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the [--nowait-nodes](#) option used with [ndbd](#) or [ndbmt](#) to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same NDB Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

### Note

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

- [--print-defaults](#)

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <a href="#">--print-defaults</a> |
|---------------------|----------------------------------|

Print program argument list and exit.

- [--print-full-config, -P](#)

|                     |                                     |
|---------------------|-------------------------------------|
| Command-Line Format | <a href="#">--print-full-config</a> |
| Type                | Boolean                             |

|               |                    |
|---------------|--------------------|
| Default Value | <code>FALSE</code> |
|---------------|--------------------|

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

- `--reload`

|                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>--reload</code> |
| Type                | Boolean               |
| Default Value       | <code>FALSE</code>    |

NDB Cluster configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see [Section 21.3.3, “NDB Cluster Configuration Files”](#)). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be deleted. Second, `--initial` forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the `--reload` option is ignored.

When `--reload` is used, the management server must be able to communicate with data nodes and any other management servers in the cluster before it attempts to read the global configuration file; otherwise, the management server fails to start. This can happen due to changes in the networking environment, such as new IP addresses for nodes or an altered firewall configuration. In such cases, you must use `--initial` instead to force the existing cached configuration to be discarded and reloaded from the file. See [Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”](#), for additional information.

- `--remove{ =name }`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--remove[ =name ]</code> |
| Platform Specific   | Windows                        |
| Type                | String                         |
| Default Value       | <code>ndb_mgmd</code>          |

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

- `--skip-config-file`

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | <code>--skip-config-file</code> |
| Type                | Boolean                         |
| Default Value       | <code>FALSE</code>              |

Do not read cluster configuration file; ignore `--initial` and `--reload` options if specified.

- [--usage](#)

|                     |                         |
|---------------------|-------------------------|
| Command-Line Format | <a href="#">--usage</a> |
|---------------------|-------------------------|

Display help text and exit; same as [--help](#).

- [--verbose, -v](#)

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <a href="#">--verbose</a> |
| Type                | Boolean                   |
| Default Value       | <code>FALSE</code>        |

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

- [--version](#)

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <a href="#">--version</a> |
|---------------------|---------------------------|

Display version information and exit.

It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See [Section 21.3.3.3, “NDB Cluster Connection Strings”](#), for information about using connection strings. [Section 21.4.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#), describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. [Section 21.3, “Configuration of NDB Cluster”](#), discusses how to set up this file.
- `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in [Section 21.5, “Management of NDB Cluster”](#).

By default, when the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the `LogDestination` configuration parameter.

- `ndb_node_id_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.
- `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.

## 21.4.5 ndb\_mgm — The NDB Cluster Management Client

The `ndb_mgm` management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are `localhost` and 1186, respectively.

Options that can be used with `ndb_mgm` are shown in the following table. Additional descriptions follow the table.

**Table 21.25 Command-line options used with the program `ndb_mgm`**

| Format                                              | Description                                                                                                                                    | Added, Deprecated, or Removed                      |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--character-sets-dir=path</code>              | Directory containing character sets                                                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retry-delay=#</code>                | Number of seconds to wait between attempts to contact management server                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-string=connection-string,</code>    | Same as --ndb-connectstring                                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     |                                                                                                                                                |                                                    |
| <code>--core-file</code>                            | Write core file on error; used in debugging                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-extra-file=path</code>             | Read given file after global files are read                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-file=path</code>                   | Read default options from given file only                                                                                                      | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-group-suffix=string</code>         | Also read groups with concat(group, suffix)                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--execute=name,</code>                        | Execute command and exit                                                                                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-e</code>                                     |                                                                                                                                                |                                                    |
| <code>--help,</code>                                | Display help text and exit                                                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-?</code>                                     |                                                                                                                                                |                                                    |
| <code>--login-path=path</code>                      | Read given path from login file                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--ndb-connectstring=connection-string,</code> | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     |                                                                                                                                                |                                                    |
| <code>--ndb-mgmd-host=connection-string,</code>     | Same as --ndb-connectstring                                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     |                                                                                                                                                |                                                    |

| Format                         | Description                                                                                                                          | Added, Deprecated, or Removed                      |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --ndb-nodeid=#                 | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-optimized-node-selection | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.7) |
| --no-defaults                  | Do not read default options from any option file other than login file                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| --print-defaults               | Print program argument list and exit                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| --try-reconnect=#, -t          | Set number of times to retry connection before giving up; synonym for --connect-retries                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --usage, -?                    | Display help text and exit; same as --help                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --version, -V                  | Display version information and exit                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- `--connect-retries=#`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Numeric                          |
| Default Value       | 3                                |
| Minimum Value       | 0                                |
| Maximum Value       | 4294967295                       |

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using `--connect-retry-delay`.

This option is synonymous with the `--try-reconnect` option, which is now deprecated.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 5                                    |

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | <code>[none]</code>                             |

Same as `--ndb-connectstring`.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | <code>[none]</code>                     |

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | <code>[none]</code>               |

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | <code>[none]</code>                         |

Also read groups with concat(group, suffix).

- `--execute=command, -e command`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--execute=name</code> |
|---------------------|-----------------------------|

This option can be used to send a command to the NDB Cluster management client from the system shell. For example, either of the following is equivalent to executing `SHOW` in the management client:

```
shell> ndb_mgm -e "SHOW"
shell> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See [Section 4.2.2.1, “Using Options on the Command Line”](#).

#### Note

If the management client command to be passed using this option contains any space characters, then the command *must* be enclosed in quotation marks. Either single or double quotation marks may be used. If the

If management client command contains no space characters, the quotation marks are optional.

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type                | String                         |
| Default Value       | [none]                         |

Read given path from login file.

- `--ndb-connectstring`

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |
| Default Value       | [none]                                             |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | [none]                                         |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | [none]                      |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--try-reconnect=number`

|                                          |                                |
|------------------------------------------|--------------------------------|
| Command-Line Format                      | <code>--try-reconnect=#</code> |
| Deprecated                               | Yes                            |
| Type ( $\geq$ 5.7.10-ndb-7.5.0)          | Numeric                        |
| Type                                     | Integer                        |
| Default Value ( $\geq$ 5.7.10-ndb-7.5.0) | 12                             |
| Default Value                            | 3                              |
| Minimum Value                            | 0                              |
| Maximum Value                            | 4294967295                     |

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to *number* before giving up and reporting an error instead.

This option is deprecated and subject to removal in a future release. Use `--connect-retries`, instead.

- `--usage`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--version`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

Additional information about using `ndb_mgm` can be found in [Section 21.5.1, “Commands in the NDB Cluster Management Client”](#).

## 21.4.6 ndb\_blob\_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

This tool can be used to check for and remove orphaned BLOB column parts from `NDB` tables, as well as to generate a file listing any orphaned parts. It is sometimes useful in diagnosing and repairing corrupted or damaged `NDB` tables containing `BLOB` or `TEXT` columns.

The basic syntax for `ndb_blob_tool` is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the `--help` option, you must specify an action to be performed by including one or more of the options `--check-orphans`, `--delete-orphans`, or `--dump-file`. These options cause `ndb_blob_tool` to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking `ndb_blob_tool`. In addition, you can optionally follow the table name with the (comma-separated) names of one or more `BLOB` or `TEXT` columns from that table. If no columns are listed, the tool works on all of the table's `BLOB` and `TEXT` columns. If you need to specify a database, use the `--database (-d)` option.

The `--verbose` option provides additional information in the output about the tool's progress.

Options that can be used with `ndb_blob_tool` are shown in the following table. Additional descriptions follow the table.

**Table 21.26 Command-line options used with the program `ndb_blob_tool`**

| Format                                           | Description                                                                        | Added, Deprecated, or Removed                      |
|--------------------------------------------------|------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--add-missing</code>                       | Write dummy blob parts to take place of those which are missing                    | ADDED: NDB 7.5.18, NDB 7.6.14                      |
| <code>--character-sets-dir=path</code>           | Directory containing character sets                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--check-missing</code>                     | Check for blobs having inline parts but missing one or more parts from parts table | ADDED: NDB 7.5.18, NDB 7.6.14                      |
| <code>--check-orphans</code>                     | Check for blob parts having no corresponding inline parts                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retries=#</code>                 | Number of times to retry connection before giving up                               | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retry-delay=#</code>             | Number of seconds to wait between attempts to contact management server            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-string=connection-string,</code> | Same as <code>--ndb-connectstring</code>                                           | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                  |                                                                                    |                                                    |
| <code>--core-file</code>                         | Write core file on error; used in debugging                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--database=db_name,</code>                 | Database to find the table in                                                      | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-d</code>                                  |                                                                                    |                                                    |
| <code>--defaults-extra-file=path</code>          | Read given file after global files are read                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-file=path</code>                | Read default options from given file only                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-group-suffix=string</code>      | Also read groups with <code>concat(group, suffix)</code>                           | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--delete-orphans</code>                    | Delete blob parts having no corresponding inline parts                             | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--dump-file=file</code>                    | Write orphan keys to specified file                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--help,</code>                             | Display help text and exit                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-?</code>                                  |                                                                                    |                                                    |
| <code>--login-path=path</code>                   | Read given path from login file                                                    | (Supported in all NDB releases based on MySQL 5.7) |

| Format                                       | Description                                                                                                                                              | Added, Deprecated, or Removed                      |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --ndb-connectstring=connection-string,<br>-c | Set connect string for connecting to ndb_mgmd.<br>Syntax: "[nodeid=id;]<br>[host=]hostname[:port]".<br>Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-mgmd-host=connection-string,<br>-c     | Same as --ndb-connectstring                                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-nodeid=#                               | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-optimized-node-selection               | Enable optimizations for selection of nodes for transactions.<br>Enabled by default; use --skip-ndb-optimized-node-selection to disable                  | (Supported in all NDB releases based on MySQL 5.7) |
| --no-defaults                                | Do not read default options from any option file other than login file                                                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| --print-defaults                             | Print program argument list and exit                                                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --usage,<br>-?                               | Display help text and exit; same as --help                                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| --verbose,<br>-v                             | Verbose output                                                                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --version,<br>-V                             | Display version information and exit                                                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |

- [--add-missing](#)

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <a href="#">--add-missing</a> |
| Introduced          | 5.7.29-ndb-7.6.14             |
| Type                | Boolean                       |
| Default Value       | <code>FALSE</code>            |

For each inline part in NDB Cluster tables which has no corresponding BLOB part, write a dummy BLOB part of the required length, consisting of spaces.

- [--character-sets-dir](#)

|                     |                                           |
|---------------------|-------------------------------------------|
| Command-Line Format | <a href="#">--character-sets-dir=path</a> |
|---------------------|-------------------------------------------|

Directory containing character sets.

- [--check-missing](#)

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | <a href="#">--check-missing</a> |
|---------------------|---------------------------------|

|               |                    |
|---------------|--------------------|
| Introduced    | 5.7.29-ndb-7.6.14  |
| Type          | Boolean            |
| Default Value | <code>FALSE</code> |

Check for inline parts in NDB Cluster tables which have no corresponding BLOB parts.

- `--check-orphans`

|                     |                              |
|---------------------|------------------------------|
| Command-Line Format | <code>--check-orphans</code> |
| Type                | Boolean                      |
| Default Value       | <code>FALSE</code>           |

Check for BLOB parts in NDB Cluster tables which have no corresponding inline parts.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | <code>12</code>                  |
| Minimum Value       | <code>0</code>                   |
| Maximum Value       | <code>12</code>                  |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | <code>5</code>                       |
| Minimum Value       | <code>0</code>                       |
| Maximum Value       | <code>5</code>                       |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | <code>[none]</code>                             |

Same as `--ndb-connectstring`.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database=db_name, -d`

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | <code>--database=db_name</code> |
| Type                | String                          |
| Default Value       | <code>[none]</code>             |

Specify the database to find the table in.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | <code>[none]</code>                     |

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | <code>[none]</code>               |

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | <code>[none]</code>                         |

Also read groups with concat(group, suffix).

- `--delete-orphans`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--delete-orphans</code> |
| Type                | Boolean                       |
| Default Value       | <code>FALSE</code>            |

Remove BLOB parts from NDB Cluster tables which have no corresponding inline parts.

- `--dump-file=file`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--dump-file=file</code> |
| Type                | File name                     |
| Default Value       | <code>[none]</code>           |

Writes a list of orphaned BLOB column parts to `file`. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type                | String                         |
| Default Value       | <code>[none]</code>            |

Read given path from login file.

- `--ndb-connectstring`

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |
| Default Value       | [none]                                             |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | [none]                                         |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | [none]                      |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--usage`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--verbose`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--verbose</code> |
| Type                | Boolean                |

|               |       |
|---------------|-------|
| Default Value | FALSE |
|---------------|-------|

Provide extra information in the tool's output regarding its progress.

- `--version`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

## Example

First we create an `NDB` table in the `test` database, using the `CREATE TABLE` statement shown here:

```
USE test;

CREATE TABLE btest (
 c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
 c1 TEXT,
 c2 BLOB
) ENGINE=NDB;
```

Then we insert a few rows into this table, using a series of statements similar to this one:

```
INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));
```

When run with `--check-orphans` against this table, `ndb_blob_tool` generates the following output:

```
shell> ndb_blob_tool --check-orphans --verbose -d test btest
connected
processing 2 blobs
processing blob #0 c1 NDB$BLOB_19_1
NDB$BLOB_19_1: nextResult: res=1
total parts: 0
orphan parts: 0
processing blob #1 c2 NDB$BLOB_19_2
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=1
total parts: 10
orphan parts: 0
disconnected

NDBT_ProgramExit: 0 - OK
```

The tool reports that there are no `NDB` BLOB column parts associated with column `c1`, even though `c1` is a `TEXT` column. This is due to the fact that, in an `NDB` table, only the first 256 bytes of a `BLOB` or `TEXT` column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values using more than 256 bytes in a given column of one of these types, no `BLOB` column parts are created by `NDB` for this column. See [Section 11.7, “Data Type Storage Requirements”](#), for more information.

## 21.4.7 ndb\_config — Extract NDB Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: an NDB Cluster management node, or its `config.ini` or `my.cnf` file. By default, the management node is the source for the configuration data; to override the default, execute `ndb_config` with the `--config-file` or `--mycnf` option. It is also possible to use a data node as the source by specifying its node ID with `--config_from_node=node_id`.

`ndb_config` can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the `--configinfo` and `--xml` options later in this section).

You can filter the results by section (`DB`, `SYSTEM`, or `CONNECTIONS`) using one of the options `--nodes`, `--system`, or `--connections`.

Options that can be used with `ndb_config` are shown in the following table. Additional descriptions follow the table.

**Table 21.27 Command-line options used with the program `ndb_config`**

| Format                                           | Description                                                                                                                                                                                                        | Added, Deprecated, or Removed                      |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--character-sets-dir=path</code>           | Directory containing character sets                                                                                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--config-file=file_name</code>             | Set the path to config.ini file                                                                                                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--config-from-node=#</code>                | Obtain configuration data from the node having this ID (must be a data node)                                                                                                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--configinfo</code>                        | Dumps information about all NDB configuration parameters in text format with default, maximum, and minimum values. Use with <code>--xml</code> to obtain XML output                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connections</code>                       | Print connections information ([tcp], [tcp default], [sci], [sci default], [shm], or [shm default] sections of cluster configuration file) only. Cannot be used with <code>--system</code> or <code>--nodes</code> | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retries=#</code>                 | Number of times to retry connection before giving up                                                                                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retry-delay=#</code>             | Number of seconds to wait between attempts to contact management server                                                                                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-string=connection-string,</code> | Same as <code>--ndb-connectstring</code>                                                                                                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                  |                                                                                                                                                                                                                    |                                                    |
| <code>--core-file</code>                         | Write core file on error; used in debugging                                                                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-extra-file=path</code>          | Read given file after global files are read                                                                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-file=path</code>                | Read default options from given file only                                                                                                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-group-suffix=string</code>      | Also read groups with concat(group, suffix)                                                                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--diff-default</code>                      | Print only configuration parameters that have non-default values                                                                                                                                                   | ADDED: NDB 7.5.7, NDB 7.6.3                        |

| <b>Format</b>                                | <b>Description</b>                                                                                                                                    | <b>Added, Deprecated, or Removed</b>               |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --fields=string,<br>-f                       | Field separator                                                                                                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| --help,                                      | Display help text and exit                                                                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| -?                                           |                                                                                                                                                       |                                                    |
| --host=name                                  | Specify host                                                                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| --login-path=path                            | Read given path from login file                                                                                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| --mycnf                                      | Read configuration data from my.cnf file                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-connectstring=connection-string,<br>-c | Set connect string for connecting to ndb_mgmd.<br>Syntax: "[nodeid=id]; [host=]hostname[:port]".<br>Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-mgmd-host=connection-string,<br>-c     | Same as --ndb-connectstring                                                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-nodeid=#                               | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-optimized-node-selection               | Enable optimizations for selection of nodes for transactions.<br>Enabled by default; use --skip-ndb-optimized-node-selection to disable               | (Supported in all NDB releases based on MySQL 5.7) |
| --no-defaults                                | Do not read default options from any option file other than login file                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| --nodeid                                     | Get configuration of node with this ID                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| --nodes                                      | Print node information ([ndbd] or [ndbd default] section of cluster configuration file) only. Cannot be used with --system or --connections           | (Supported in all NDB releases based on MySQL 5.7) |
| --query=string,<br>-q                        | One or more query options (attributes)                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| --query-all,<br>-a                           | Dumps all parameters and values to a single comma-delimited string                                                                                    | ADDED: NDB 7.4.16, NDB 7.5.7                       |
| --print-defaults                             | Print program argument list and exit                                                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| --rows=string,<br>-r                         | Row separator                                                                                                                                         | (Supported in all NDB releases based on MySQL 5.7) |

| Format             | Description                                                                                                                              | Added, Deprecated, or Removed                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --system           | Print SYSTEM section information only (see ndb_config --configinfo output). Cannot be used with --nodes or --connections                 | (Supported in all NDB releases based on MySQL 5.7) |
| --type=name        | Specify node type                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| --usage,<br>-?     | Display help text and exit; same as --help                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| --version,<br>-V   | Display version information and exit                                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --configinfo --xml | Use --xml with --configinfo to obtain a dump of all NDB configuration parameters in XML format with default, maximum, and minimum values | (Supported in all NDB releases based on MySQL 5.7) |

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- `--configinfo`

The `--configinfo` option causes `ndb_config` to dump a list of each NDB Cluster configuration parameter supported by the NDB Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage
- The section of the `config.ini` file where the parameter may be used
- The parameter's data type or unit of measurement
- Where applicable, the parameter's default, minimum, and maximum values
- NDB Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```
shell> ndb_config --configinfo

***** SYSTEM *****

Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)
```

```
***** DB *****

MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

...
```

Use this option together with the `--xml` option to obtain output in XML format.

- `--config-file=path-to-file`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--config-file=file_name</code> |
| Type                | File name                            |
| Default Value       |                                      |

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--config_from_node=#`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--config-from-node=#</code> |
| Type                | Numeric                           |
| Default Value       | <code>none</code>                 |
| Minimum Value       | <code>1</code>                    |
| Maximum Value       | <code>48</code>                   |

Obtain the cluster's configuration data from the data node that has this ID.

If the node having this ID is not a data node, `ndb_config` fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

- `--connections`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--connections</code> |
| Type                | Boolean                    |
| Default Value       | <code>FALSE</code>         |

Tells `ndb_config` to print `CONNECTIONS` information only—that is, information about parameters found in the `[tcp]`, `[tcp default]`, `[shm]`, or `[shm default]` sections of the cluster configuration file (see [Section 21.3.3.10, “NDB Cluster TCP/IP Connections”](#), and [Section 21.3.3.12, “NDB Cluster Shared Memory Connections”](#), for more information).

This option is mutually exclusive with `--nodes` and `--system`; only one of these 3 options can be used.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | <code>12</code>                  |
| Minimum Value       | <code>0</code>                   |

|               |    |
|---------------|----|
| Maximum Value | 12 |
|---------------|----|

Number of times to retry connection before giving up.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 5                                    |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | [none]                                          |

Same as `--ndb-connectstring`.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | [none]                                  |

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | [none]                            |

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | [none]                                      |

Also read groups with concat(group, suffix).

- `--diff-default`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--diff-default</code> |
|---------------------|-----------------------------|

|               |                    |
|---------------|--------------------|
| Introduced    | 5.7.18-ndb-7.6.3   |
| Type          | Boolean            |
| Default Value | <code>FALSE</code> |

Print only configuration parameters that have non-default values.

- `--fields=delimiter, -f delimiter`

|                     |                              |
|---------------------|------------------------------|
| Command-Line Format | <code>--fields=string</code> |
| Type                | String                       |
| Default Value       |                              |

Specifies a `delimiter` string used to separate the fields in the result. The default is `,` (the comma character).

#### Note

If the `delimiter` contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--host=hostname`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--host=name</code> |
| Type                | String                   |
| Default Value       |                          |

Specifies the host name of the node for which configuration information is to be obtained.

#### Note

While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all NDB Cluster configuration values relating to hosts, or verify that all NDB Cluster hosts handle `localhost` in the same fashion.

- `--login-path`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type                | String                         |
| Default Value       | <code>[none]</code>            |

Read given path from login file.

- `--mycnf`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--mycnf</code> |
| Type                | Boolean              |
| Default Value       | <code>FALSE</code>   |

Read configuration data from the `my.cnf` file.

- `--ndb-connectstring=connection_string, -c connection_string`

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |
| Default Value       | <code>[none]</code>                                |

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in [Section 21.3.3.3, “NDB Cluster Connection Strings”](#), and defaults to `localhost:1186`.

- `--ndb-mgmd-host`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | <code>[none]</code>                            |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | <code>[none]</code>         |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--nodeid=node_id`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | <code>[none]</code>         |

Specify the node ID of the node for which configuration information is to be obtained. Formerly, `--id` could be used as a synonym for this option; in NDB 7.5 and later, the only form accepted is `--nodeid`.

- `--nodes`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--nodes</code> |
| Type                | Boolean              |
| Default Value       | <code>FALSE</code>   |

Tells `ndb_config` to print information relating only to parameters defined in an `[ndbd]` or `[ndbd default]` section of the cluster configuration file (see [Section 21.3.3.6, “Defining NDB Cluster Data Nodes”](#)).

This option is mutually exclusive with `--connections` and `--system`; only one of these 3 options can be used.

- `--query=query-options, -q query-options`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--query=string</code> |
| Type                | String                      |
| Default Value       |                             |

This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include `nodeid` (node ID), type (node type—that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=nodeid,type,datamemory,datadir` returns the node ID, node type, `DataMemory`, and `DataDir` for each node.

Formerly, `id` was accepted as a synonym for `nodeid`, but has been removed in NDB 7.5 and later.

#### Note

If a given parameter is not applicable to a certain type of node, than an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--query-all, -a`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--query-all</code> |
| Introduced          | 5.7.18-ndb-7.5.7         |
| Type                | String                   |
| Default Value       |                          |

Returns a comma-delimited list of all query options (node attributes; note that this list is a single string).

This option was introduced in NDB 7.5.7 (Bug #60095, Bug #11766869).

- `--print-defaults`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--rows=separator, -r separator`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--rows=string</code> |
| Type                | String                     |

|               |  |
|---------------|--|
| Default Value |  |
|---------------|--|

Specifies a *separator* string used to separate the rows in the result. The default is a space character.

#### Note

If the *separator* contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

- `--system`

|                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>--system</code> |
| Type                | Boolean               |
| Default Value       | <code>FALSE</code>    |

Tells `ndb_config` to print `SYSTEM` information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for them. They can be seen (prefixed with `***** SYSTEM *****`) in the output of `ndb_config --configinfo`.

This option is mutually exclusive with `--nodes` and `--connections`; only one of these 3 options can be used.

- `--type=node_type`

|                     |                                                                   |
|---------------------|-------------------------------------------------------------------|
| Command-Line Format | <code>--type=name</code>                                          |
| Type                | Enumeration                                                       |
| Default Value       | <code>[none]</code>                                               |
| Valid Values        | <code>ndbd</code><br><code>mysqld</code><br><code>ndb_mgmd</code> |

Filters results so that only configuration values applying to nodes of the specified *node\_type* (`ndbd`, `mysqld`, or `ndb_mgmd`) are returned.

- `--usage`, `--help`, or `-?`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Causes `ndb_config` to print a list of available options, and then exit. Synonym for `--help`.

- `--version`, `-V`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Causes `ndb_config` to print a version information string, and then exit.

- `--configinfo --xml`

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | <code>--configinfo --xml</code> |
| Type                | Boolean                         |

|               |                    |
|---------------|--------------------|
| Default Value | <code>false</code> |
|---------------|--------------------|

Cause `ndb_config --configinfo` to provide output as XML by adding this option. A portion of such output is shown in this example:

```
shell> ndb_config --configinfo --xml

<configvariables protocolversion="1" ndbversionstring="5.7.33-ndb-7.5.23"
 ndbversion="460032" ndbversionmajor="7" ndbversionminor="5"
 ndbversionbuild="0">
 <section name="SYSTEM">
 <param name="Name" comment="Name of system (NDB Cluster)" type="string"
 mandatory="true"/>
 <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd(MGM) node"
 type="unsigned" default="0" min="0" max="4294967039"/>
 <param name="ConfigGenerationNumber" comment="Configuration generation number"
 type="unsigned" default="0" min="0" max="4294967039"/>
 </section>
 <section name="MYSQLD" primarykeys="NodeId">
 <param name="wan" comment="Use WAN TCP setting as default" type="bool"
 default="false"/>
 <param name="HostName" comment="Name of computer for this node"
 type="string" default="" />
 <param name="Id" comment="NodeId" type="unsigned" mandatory="true"
 min="1" max="255" deprecated="true"/>
 <param name="NodeId" comment="Number identifying application node (mysqld(API))"
 type="unsigned" mandatory="true" min="1" max="255"/>
 <param name="ExecuteOnComputer" comment="HostName" type="string"
 deprecated="true"/>
 ...
 </section>
 ...
</configvariables>
```

### Note

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

The XML output also indicates when changing a given parameter requires that data nodes be restarted using the `--initial` option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition, the restart type (`system` or `node`) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a `restart="system"` attribute in the corresponding `<param>` element. For example, changing the value set for the `Diskless` parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
 restart="system" initial="true"/>
```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is `node` (that is, an online or “rolling” restart of the cluster), but the `restart` attribute is included

only if the restart type is `system` (meaning that all cluster nodes must be shut down at the same time, then restarted).

Deprecated parameters are indicated in the XML output by the `deprecated` attribute, as shown here:

```
<param name="NoOfDiskPagesToDiskAfterRestartACC" comment="DiskCheckpointSpeed"
 type="unsigned" default="20" min="1" max="4294967039" deprecated="true" />
```

In such cases, the `comment` refers to one or more parameters that supersede the deprecated parameter. Similarly to `initial`, the `deprecated` attribute is indicated only when the parameter is deprecated, with `deprecated="true"`, and does not appear at all for parameters which are not deprecated. (Bug #21127135)

Beginning with NDB 7.5.0, parameters that are required are indicated with `mandatory="true"`, as shown here:

```
<param name="NodeId"
 comment="Number identifying application node (mysqld(API))"
 type="unsigned" mandatory="true" min="1" max="255"/>
```

In much the same way that the `initial` or `deprecated` attribute is displayed only for a parameter that requires an initial restart or that is deprecated, the `mandatory` attribute is included only if the given parameter is actually required.

### Important

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the NDB Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running NDB Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` (with or without the `--xml` option) is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored. *However, this behavior is not guaranteed and is subject to change at any time.* In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the NDB Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

## Examples

- To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=nodeid,type --fields=':' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysqld
7:mysqld
8:mysqld
9:mysqld
```

In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (`:`), and the `--rows` options to place the values for each node on a new line in the output.

- To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

```
shell> ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini \
--query=hostname,portnumber --fields=: --rows=, --type=ndb_mgmd
198.51.100.179:1186
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, as well as the values set for its `DataMemory` and `DataDir` parameters:

```
shell> ./ndb_config --type=ndbd --query=nodeid,host,datamemory,datadir -f ' : ' -r '\n'
1 : 198.51.100.193 : 83886080 : /usr/local/mysql/cluster-data
2 : 198.51.100.112 : 83886080 : /usr/local/mysql/cluster-data
3 : 198.51.100.176 : 83886080 : /usr/local/mysql/cluster-data
4 : 198.51.100.119 : 83886080 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively, as well as the short option `-q` to pass a list of parameters to be obtained.

4. To exclude results from any host except one in particular, use the `--host` option:

```
shell> ./ndb_config --host=198.51.100.176 -f : -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--nodeid` option.

## 21.4.8 ndb\_cpcd — Automate Testing for NDB Development

A utility having this name was formerly part of an internal automated test framework used in testing and debugging NDB Cluster. It is no longer included in NDB Cluster distributions provided by Oracle.

## 21.4.9 ndb\_delete\_all — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

### Usage

```
ndb_delete_all -c connection_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

Options that can be used with `ndb_delete_all` are shown in the following table. Additional descriptions follow the table.

**Table 21.28 Command-line options used with the program `ndb_delete_all`**

| Format                                           | Description                                                             | Added, Deprecated, or Removed                      |
|--------------------------------------------------|-------------------------------------------------------------------------|----------------------------------------------------|
| <code>--character-sets-dir=path</code>           | Directory containing character sets                                     | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retries=#</code>                 | Number of times to retry connection before giving up                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retry-delay=#</code>             | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-string=connection-string,</code> | Same as <code>--ndb-connectstring</code>                                | (Supported in all NDB releases based on MySQL 5.7) |

| Format                                              | Description                                                                                                                                        | Added, Deprecated, or Removed                      |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>-c</code>                                     |                                                                                                                                                    |                                                    |
| <code>--core-file</code>                            | Write core file on error; used in debugging                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--database=dbname,</code>                     | Name of the database in which the table is found                                                                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-d</code>                                     |                                                                                                                                                    |                                                    |
| <code>--defaults-extra-file=path</code>             | Read given file after global files are read                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-file=path</code>                   | Read default options from given file only                                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-group-suffix=string</code>         | Also read groups with concat(group, suffix)                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--diskscan</code>                             | Run disk scan                                                                                                                                      | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--help,</code>                                | Display help text and exit                                                                                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-?</code>                                     |                                                                                                                                                    |                                                    |
| <code>--login-path=path</code>                      | Read given path from login file                                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--ndb-connectstring=connection-string,</code> | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;]<br>[host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     |                                                                                                                                                    |                                                    |
| <code>--ndb-mgmd-host=connection-string,</code>     | Same as --ndb-connectstring                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     |                                                                                                                                                    |                                                    |
| <code>--ndb-nodeid=#</code>                         | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--ndb-optimized-node-selection</code>         | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable               | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--no-defaults</code>                          | Do not read default options from any option file other than login file                                                                             | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--print-defaults</code>                       | Print program argument list and exit                                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--transactional,</code>                       | Perform the delete in a single transaction (may run out of operations)                                                                             | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-t</code>                                     |                                                                                                                                                    |                                                    |
| <code>--tupscan</code>                              | Run tup scan                                                                                                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--usage,</code>                               | Display help text and exit; same as --help                                                                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-?</code>                                     |                                                                                                                                                    |                                                    |

| Format           | Description                          | Added, Deprecated, or Removed                      |
|------------------|--------------------------------------|----------------------------------------------------|
| --version,<br>-V | Display version information and exit | (Supported in all NDB releases based on MySQL 5.7) |

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | 12                               |
| Minimum Value       | 0                                |
| Maximum Value       | 12                               |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 5                                    |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | [none]                                          |

Same as --ndb-connectstring.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database, -d`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--database=dbname</code> |
| Type                | String                         |
| Default Value       | TEST_DB                        |

Name of the database containing the table to delete from.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | [none]                                  |

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | [none]                            |

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | [none]                                      |

Also read groups with concat(group, suffix).

- `--diskscan`

|                     |                         |
|---------------------|-------------------------|
| Command-Line Format | <code>--diskscan</code> |
| Type                | Boolean                 |
| Default Value       | FALSE                   |

Run a disk scan.

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type                | String                         |
| Default Value       | [none]                         |

Read given path from login file.

- `--ndb-connectstring`

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |
| Default Value       | [none]                                             |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | [none]                                         |

Same as --ndb-connectstring.

- `--ndb-nodeid`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | [none]                      |

Set node ID for this node, overriding any ID set by --ndb-connectstring.

- `--ndb-optimized-node-selection`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--transactional, -t`

Use of this option causes the delete operation to be performed as a single transaction.

### Warning

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

- `--tupscan`

Run a tuple scan.

- `--usage`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as --help.

- `--version`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

## 21.4.10 ndb\_desc — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.

### Usage

```
ndb_desc -c connection_string tbl_name -d db_name [options]
ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with `ndb_desc` are listed later in this section.

### Sample Output

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
 id INT(11) NOT NULL AUTO_INCREMENT,
 name VARCHAR(20) NOT NULL,
 length_mm INT(11) NOT NULL,
 weight_gm INT(11) NOT NULL,
 PRIMARY KEY pk (id),
 UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES
 (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
 (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
 (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 2500);
```

Output from `ndb_desc`:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 337
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 2
FragmentCount: 2
PartitionBalance: FOR_RP_BY_LDM

## ndb\_desc — Describe NDB Tables

| Partition | Row count | Commit count | Frag fixed memory | Frag varsized memory | Extent_ |
|-----------|-----------|--------------|-------------------|----------------------|---------|
| 0         | 2         | 2            | 32768             | 32768                | 0       |
| 1         | 4         | 4            | 32768             | 32768                | 0       |

NDBT\_ProgramExit: 0 - OK

Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

You can obtain additional information about a specific index using the `--table` (short form: `-t`) option and supplying the name of the index as the first argument to `ndb_desc`, as shown here:

```
shell> ./ndb_desc uk -d test -t fish
-- uk --
Version: 2
Base table: fish
Number of attributes: 1
Logging: 0
Index type: OrderedIndex
Index status: Retrieved
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
-- IndexTable 10/uk --
Version: 2
Fragment type: FragUndefined
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: yes
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 0
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 2
ForceVarPart: 0
PartitionCount: 2
FragmentCount: 2
FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
NDB$TNODE Unsigned [64] PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(NDB$TNODE) - UniqueHashIndex

NDBT_ProgramExit: 0 - OK
```

When an index is specified in this way, the `--extra-partition-info` and `--extra-node-info` options have no effect.

The `Version` column in the output contains the table's schema object version. For information about interpreting this value, see [NDB Schema Object Versions](#).

Three of the table properties that can be set using `NDB_TABLE` comments embedded in `CREATE TABLE` and `ALTER TABLE` statements are also visible in `ndb_desc` output. The table's `FRAGMENT_COUNT_TYPE` is always shown in the `FragmentCountType` column. `READ_ONLY` and `FULLY_REPLICATED`, if set to 1, are shown in the `Table options` column. You can see this after executing the following `ALTER TABLE` statement in the `mysql` client:

```
mysql> ALTER TABLE fish COMMENT='NDB_TABLE=READ_ONLY=1,FULLY_REPLICATED=1';
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
+-----+-----+
```

```
| Level | Code | Message
+-----+-----+
| Warning | 1296 | Got error 4503 'Table property is FRAGMENT_COUNT_TYPE=ONE_PER_LDM_PER_NODE but not in co
+-----+-----+
1 row in set (0.00 sec)
```

The warning is issued because `READ_ONLY=1` requires that the table's fragment count type is (or be set to) `ONE_PER_LDM_PER_NODE_GROUP`; NDB sets this automatically in such cases. You can check that the `ALTER TABLE` statement has the desired effect using `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE fish\G
***** 1. row *****
 Table: fish
Create Table: CREATE TABLE `fish` (
 `id` int(11) NOT NULL AUTO_INCREMENT,
 `name` varchar(20) NOT NULL,
 `length_mm` int(11) NOT NULL,
 `weight_gm` int(11) NOT NULL,
 PRIMARY KEY (`id`),
 UNIQUE KEY `uk` (`name`)
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
COMMENT='NDB_TABLE=READ_BACKUP=1,FULLY_REPLICATED=1'
1 row in set (0.01 sec)
```

Because `FRAGMENT_COUNT_TYPE` was not set explicitly, its value is not shown in the comment text printed by `SHOW CREATE TABLE`. `ndb_desc`, however, displays the updated value for this attribute. The `Table options` column shows the binary properties just enabled. You can see this in the output shown here (emphasized text):

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 4
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no

Partition Row count Commit count Frag fixed memory Frag varsized memory Extent_space
NDBT_ProgramExit: 0 - OK
```

For more information about these table properties, see [Section 13.1.18.9, “Setting NDB\\_TABLE Options”](#).

The `Extent_space` and `Free extent_space` columns are applicable only to `NDB` tables having columns on disk; for tables having only in-memory columns, these columns always contain the value `0`.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```
CREATE LOGFILE GROUP lg_1
 ADD UNDOFILE 'undo_1.log'
 INITIAL_SIZE 16M
 UNDO_BUFFER_SIZE 2M
 ENGINE NDB;

ALTER LOGFILE GROUP lg_1
 ADD UNDOFILE 'undo_2.log'
 INITIAL_SIZE 12M
 ENGINE NDB;

CREATE TABLESPACE ts_1
 ADD DATAFILE 'data_1.dat'
 USE LOGFILE GROUP lg_1
 INITIAL_SIZE 32M
 ENGINE NDB;

ALTER TABLESPACE ts_1
 ADD DATAFILE 'data_2.dat'
 INITIAL_SIZE 48M
 ENGINE NDB;
```

(For more information on the statements just shown and the objects created by them, see [Section 21.5.10.1, “NDB Cluster Disk Data Objects”](#), as well as [Section 13.1.15, “CREATE LOGFILE GROUP Statement”](#), and [Section 13.1.19, “CREATE TABLESPACE Statement”](#).)

Now we can create and populate a version of the `fish` table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```
CREATE TABLE fish (
 id INT(11) NOT NULL AUTO_INCREMENT,
 name VARCHAR(20) NOT NULL,
 length_mm INT(11) NOT NULL,
 weight_gm INT(11) NOT NULL,

 PRIMARY KEY pk (id),
 UNIQUE KEY uk (name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE=NDB;

INSERT INTO fish VALUES
 (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
 (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
 (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 2500);
```

When run against this version of the table, `ndb_desc` displays the following output:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 346
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 2
```

```

FragmentCount: 2
FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
HashMap: DEFAULT-HASHMAP-3840-2
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK
weight_gm Int NOT NULL AT=FIXED ST=DISK
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex
-- Per partition info --
Partition Row count Commit count Frag fixed memory Frag varsized memory Extent_space
0 2 2 32768 32768 1048576
1 4 4 32768 32768 1048576

NDBT_ProgramExit: 0 - OK

```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words,  $1048576 - 1044440 = 4136$  bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as [Free extent space](#) is available for storing on-disk column data from the [fish](#) table only; for this reason, it is not visible when selecting from the [INFORMATION\\_SCHEMA.FILES](#) table.

For fully replicated tables, `ndb_desc` shows only the nodes holding primary partition fragment replicas; nodes with copy fragment replicas (only) are ignored. Beginning with NDB 7.5.4, you can obtain such information, using the `mysql` client, from the `table_distribution_status`, `table_fragments`, `table_info`, and `table_replicas` tables in the `ndbinfo` database.

Options that can be used with `ndb_desc` are shown in the following table. Additional descriptions follow the table.

**Table 21.29 Command-line options used with the program `ndb_desc`**

| Format                                    | Description                                                                                       | Added, Deprecated, or Removed                      |
|-------------------------------------------|---------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --auto-inc,<br>-a                         | Show next value for AUTO_INCREMENT column if table has one                                        | ADDED: NDB 7.6.14                                  |
| --blob-info,<br>-b                        | Include partition information for BLOB tables in output. Requires that the -p option also be used | (Supported in all NDB releases based on MySQL 5.7) |
| --character-sets-dir=path                 | Directory containing character sets                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| --connect-retries=#                       | Number of times to retry connection before giving up                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --connect-retry-delay=#                   | Number of seconds to wait between attempts to contact management server                           | (Supported in all NDB releases based on MySQL 5.7) |
| --connect-string=connection-string,<br>-c | Same as --ndb-connectstring                                                                       | (Supported in all NDB releases based on MySQL 5.7) |

| Format                                       | Description                                                                                                                                        | Added, Deprecated, or Removed                      |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --context,<br>-x                             | Show extra information for table such as database, schema, name, internal ID                                                                       | ADDED: NDB 7.6.14                                  |
| --core-file                                  | Write core file on error; used in debugging                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| --database=dbname,<br>-d                     | Name of database containing table                                                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-extra-file=path                   | Read given file after global files are read                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-file=path                         | Read default options from given file only                                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-group-suffix=string               | Also read groups with concat(group, suffix)                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| --extra-node-info,<br>-n                     | Include partition-to-data-node mappings in output. Requires that the -p option also be used                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| --extra-partition-info,<br>-p                | Display information about partitions                                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| --help,                                      | Display help text and exit                                                                                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| -?                                           |                                                                                                                                                    |                                                    |
| --login-path=path                            | Read given path from login file                                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-connectstring=connection-string,<br>-c | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;]<br>[host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-mgmd-host=connection-string,<br>-c     | Same as --ndb-connectstring                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-nodeid=#                               | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-optimized-node-selection               | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable               | (Supported in all NDB releases based on MySQL 5.7) |
| --no-defaults                                | Do not read default options from any option file other than login file                                                                             | (Supported in all NDB releases based on MySQL 5.7) |
| --print-defaults                             | Print program argument list and exit                                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| --retries=#,                                 | Number of times to retry the connection (once per second)                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |

| Format                                                                                                                                                                                                           | Description                                                                                                                                                                                                                                                                                    | Added, Deprecated, or Removed                                                                                                                                                                                                           |

- `--auto-inc, -a`

Show the next value for a table's `AUTO_INCREMENT` column, if it has one.

- `--blob-info, -b`

Include information about subordinate `BLOB` and `TEXT` columns.

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | 12                               |
| Minimum Value       | 0                                |
| Maximum Value       | 12                               |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 5                                    |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | <code>[none]</code>                             |

Same as `--ndb-connectstring`.

- `--context, -x`

Show additional contextual information for the table such as schema, database name, table name, and the table's internal ID.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database=db_name, -d`

Specify the database in which the table should be found.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | <code>[none]</code>                     |

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | <code>[none]</code>               |

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | <code>[none]</code>                         |

Also read groups with concat(group, suffix).

- `--extra-node-info, -n`

Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in NDB Cluster.

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

- `--extra-partition-info, -p`

Print additional information about the table's partitions.

- [--help](#)

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- [--login-path](#)

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type                | String                         |
| Default Value       | <code>[none]</code>            |

Read given path from login file.

- [--ndb-connectstring](#)

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |
| Default Value       | <code>[none]</code>                                |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- [--ndb-mgmd-host](#)

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | <code>[none]</code>                            |

Same as --ndb-connectstring.

- [--ndb-nodeid](#)

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | <code>[none]</code>         |

Set node ID for this node, overriding any ID set by --ndb-connectstring.

- [--ndb-optimized-node-selection](#)

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use [--skip-ndb-optimized-node-selection](#) to disable.

- [--no-defaults](#)

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- [--print-defaults](#)

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--retries=#, -r`

Try to connect this many times before giving up. One connect attempt is made per second.

- `--table=tbl_name, -t`

Specify the table in which to look for an index.

- `--unqualified, -u`

Use unqualified table names.

- `--usage`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--version`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

In NDB 7.5.3 and later, table indexes listed in the output are ordered by ID. Previously, this was not deterministic and could vary between platforms. (Bug #81763, Bug #23547742)

## 21.4.11 `ndb_drop_index` — Drop Index from an NDB Table

`ndb_drop_index` drops the specified index from an [NDB](#) table. *It is recommended that you use this utility only as an example for writing NDB API applications*—see the Warning later in this section for details.

### Usage

```
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named `index` from the `table` in the `database`.

Options that can be used with `ndb_drop_index` are shown in the following table. Additional descriptions follow the table.

**Table 21.30 Command-line options used with the program `ndb_drop_index`**

| Format                                                              | Description                                                             | Added, Deprecated, or Removed                      |
|---------------------------------------------------------------------|-------------------------------------------------------------------------|----------------------------------------------------|
| <code>--character-sets-dir=path</code>                              | Directory containing character sets                                     | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retries=#</code>                                    | Number of times to retry connection before giving up                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retry-delay=#</code>                                | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-string=connection-string,</code><br><code>-c</code> | Same as <code>--ndb-connectstring</code>                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--core-file</code>                                            | Write core file on error; used in debugging                             | (Supported in all NDB releases based on MySQL 5.7) |

| Format                                       | Description                                                                                                                                        | Added, Deprecated, or Removed                      |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --database=dbname,<br>-d                     | Name of database in which table is found                                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-extra-file=path                   | Read given file after global files are read                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-file=path                         | Read default options from given file only                                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-group-suffix=string               | Also read groups with concat(group, suffix)                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| --help,                                      | Display help text and exit                                                                                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| -?                                           |                                                                                                                                                    |                                                    |
| --login-path=path                            | Read given path from login file                                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-connectstring=connection-string,<br>-c | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;]<br>[host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-mgmd-host=connection-string,<br>-c     | Same as --ndb-connectstring                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-nodeid=#                               | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-optimized-node-selection               | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable               | (Supported in all NDB releases based on MySQL 5.7) |
| --no-defaults                                | Do not read default options from any option file other than login file                                                                             | (Supported in all NDB releases based on MySQL 5.7) |
| --print-defaults                             | Print program argument list and exit                                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| --usage,<br>-?                               | Display help text and exit; same as --help                                                                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| --version,<br>-V                             | Display version information and exit                                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | 12                               |
| Minimum Value       | 0                                |
| Maximum Value       | 12                               |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 5                                    |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | [none]                                          |

Same as `--ndb-connectstring`.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database, -d`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--database=dbname</code> |
| Type                | String                         |
| Default Value       | TEST_DB                        |

Name of the database in which the table resides.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | [none]                                  |

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |

|               |        |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | [none]                                      |

Also read groups with concat(group, suffix).

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type                | String                         |
| Default Value       | [none]                         |

Read given path from login file.

- `--ndb-connectstring`

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |
| Default Value       | [none]                                             |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | [none]                                         |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | [none]                      |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- [--ndb-optimized-node-selection](#)

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use [--skip-ndb-optimized-node-selection](#) to disable.

- [--no-defaults](#)

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- [--print-defaults](#)

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- [--usage](#)

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as [--help](#).

- [--version](#)

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

### Warning

*Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:*

```
shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Enter password: *****
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.7.33-ndb-7.5.23

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW TABLES;
+-----+
| Tables_in_ctest1 |
+-----+
| a |
| bt1 |
| bt2 |
| dogs |
| employees |
| fish |
+-----+
6 rows in set (0.00 sec)
```

```
mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER
```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement [DROP TABLE](#) or the [ndb\\_drop\\_table](#) utility (see [Section 21.4.12, “ndb\\_drop\\_table — Drop an NDB Table”](#)) to drop the table.

## 21.4.12 ndb\_drop\_table — Drop an NDB Table

[ndb\\_drop\\_table](#) drops the specified [NDB](#) table. (If you try to use this on a table created with a storage engine other than [NDB](#), the attempt fails with the error [723: No such table exists](#).) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL [DROP TABLE](#) statement on an [NDB](#) table.

### Usage

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

Options that can be used with [ndb\\_drop\\_table](#) are shown in the following table. Additional descriptions follow the table.

**Table 21.31 Command-line options used with the program ndb\_drop\_table**

| Format                                 | Description                                                                         | Added, Deprecated, or Removed                      |
|----------------------------------------|-------------------------------------------------------------------------------------|----------------------------------------------------|
| --character-sets-dir=path              | Directory containing character sets                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| --connect-retries=#                    | Number of times to retry connection before giving up                                | (Supported in all NDB releases based on MySQL 5.7) |
| --connect-retry-delay=#                | Number of seconds to wait between attempts to contact management server             | (Supported in all NDB releases based on MySQL 5.7) |
| --connect-string=connection-string,    | Same as --ndb-connectstring                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| -c                                     |                                                                                     |                                                    |
| --core-file                            | Write core file on error; used in debugging                                         | (Supported in all NDB releases based on MySQL 5.7) |
| --database=dbname,                     | Name of database in which table is found                                            | (Supported in all NDB releases based on MySQL 5.7) |
| -d                                     |                                                                                     |                                                    |
| --defaults-extra-file=path             | Read given file after global files are read                                         | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-file=path                   | Read default options from given file only                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-group-suffix=string         | Also read groups with concat(group, suffix)                                         | (Supported in all NDB releases based on MySQL 5.7) |
| --help,                                | Display help text and exit                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| -?                                     |                                                                                     |                                                    |
| --login-path=path                      | Read given path from login file                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-connectstring=connection-string, | Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: "[nodeid=id;]" | (Supported in all NDB releases based on MySQL 5.7) |

| Format                                          | Description                                                                                                                                | Added, Deprecated, or Removed                      |
|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>-c</code>                                 | [host=]hostname[:port]" .<br>Overrides entries in<br>NDB_CONNECTSTRING and<br>my.cnf                                                       |                                                    |
| <code>--ndb-mgmd-host=connection-string,</code> | Same as --ndb-connectstring                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                 |                                                                                                                                            |                                                    |
| <code>--ndb-nodeid=#</code>                     | Set node ID for this node,<br>overriding any ID set by --ndb-connectstring                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--ndb-optimized-node-selection</code>     | Enable optimizations for selection<br>of nodes for transactions.<br>Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--no-defaults</code>                      | Do not read default options from<br>any option file other than login file                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--print-defaults</code>                   | Print program argument list and<br>exit                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--usage,</code>                           | Display help text and exit; same<br>as --help                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-?</code>                                 |                                                                                                                                            |                                                    |
| <code>--version,</code>                         | Display version information and<br>exit                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-V</code>                                 |                                                                                                                                            |                                                    |

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | 12                               |
| Minimum Value       | 0                                |
| Maximum Value       | 12                               |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |

|               |   |
|---------------|---|
| Maximum Value | 5 |
|---------------|---|

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | [none]                                          |

Same as `--ndb-connectstring`.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database, -d`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--database=dbname</code> |
| Type                | String                         |
| Default Value       | TEST_DB                        |

Name of the database in which the table resides.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | [none]                                  |

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | [none]                            |

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | [none]                                      |

Also read groups with concat(group, suffix).

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

- [--login-path](#)

|                     |                   |
|---------------------|-------------------|
| Command-Line Format | --login-path=path |
| Type                | String            |
| Default Value       | [none]            |

Read given path from login file.

- [--ndb-connectstring](#)

|                     |                                       |
|---------------------|---------------------------------------|
| Command-Line Format | --ndb-connectstring=connection-string |
| Type                | String                                |
| Default Value       | [none]                                |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- [--ndb-mgmd-host](#)

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | --ndb-mgmd-host=connection-string |
| Type                | String                            |
| Default Value       | [none]                            |

Same as [--ndb-connectstring](#).

- [--ndb-nodeid](#)

|                     |                |
|---------------------|----------------|
| Command-Line Format | --ndb-nodeid=# |
| Type                | Integer        |
| Default Value       | [none]         |

Set node ID for this node, overriding any ID set by [--ndb-connectstring](#).

- [--ndb-optimized-node-selection](#)

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | --ndb-optimized-node-selection |
|---------------------|--------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use [--skip-ndb-optimized-node-selection](#) to disable.

- [--no-defaults](#)

|                     |               |
|---------------------|---------------|
| Command-Line Format | --no-defaults |
|---------------------|---------------|

Do not read default options from any option file other than login file.

- [--print-defaults](#)

|                     |                  |
|---------------------|------------------|
| Command-Line Format | --print-defaults |
|---------------------|------------------|

Print program argument list and exit.

- [--usage](#)

|                     |         |
|---------------------|---------|
| Command-Line Format | --usage |
|---------------------|---------|

Display help text and exit; same as [--help](#).

- `--version`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

## 21.4.13 ndb\_error\_reporter — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in NDB Cluster.*

Options that can be used with `ndb_error_reporter` are shown in the following table. Additional descriptions follow the table.

**Table 21.32 Command-line options used with the program ndb\_error\_reporter**

| Format                                     | Description                                                                    | Added, Deprecated, or Removed                      |
|--------------------------------------------|--------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--connection-timeout=timeout</code>  | Number of seconds to wait when connecting to nodes before timing out           | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--dry-scp</code>                     | Disable scp with remote hosts; used only for testing                           | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--fs</code>                          | Include file system data in error report; can use a large amount of disk space | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--help</code> ,<br><code>-?</code>   | Display help text and exit                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--skip-nodegroup=nodegroup_id</code> | Skip all nodes in the node group having this ID                                | (Supported in all NDB releases based on MySQL 5.7) |

## Usage

```
ndb_error_reporter path/to/config-file [username] [options]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named `config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDhhmmss.tar.bz2`, where `YYYYMMDDhhmmss` is a datetime string.

`ndb_error_reporter` also accepts the options listed here:

- `--connection-timeout=timeout`

|                     |                                           |
|---------------------|-------------------------------------------|
| Command-Line Format | <code>--connection-timeout=timeout</code> |
| Type                | Integer                                   |
| Default Value       | 0                                         |

Wait this many seconds when trying to connect to nodes before timing out.

- `--dry-scp`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--dry-scp</code> |
|---------------------|------------------------|

|               |         |
|---------------|---------|
| Type          | Boolean |
| Default Value | TRUE    |

Run `ndb_error_reporter` without using scp from remote hosts. Used for testing only.

- `--fs`

|                     |                   |
|---------------------|-------------------|
| Command-Line Format | <code>--fs</code> |
| Type                | Boolean           |
| Default Value       | FALSE             |

Copy the data node file systems to the management host and include them in the archive.

Because data node file systems can be extremely large, even after being compressed, we ask that you please do *not* send archives created using this option to Oracle unless you are specifically requested to do so.

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--skip-nodegroup=nodegroup_id`

|                     |                                           |
|---------------------|-------------------------------------------|
| Command-Line Format | <code>--connection-timeout=timeout</code> |
| Type                | Integer                                   |
| Default Value       | 0                                         |

Skip all nodes belong to the node group having the supplied node group ID.

## 21.4.14 ndb\_import — Import CSV Data Into NDB

`ndb_import` imports CSV-formatted data, such as that produced by `mysqldump --tab`, directly into NDB using the NDB API. `ndb_import` requires a connection to an NDB management server (`ndb_mgmd`) to function; it does not require a connection to a MySQL Server.

### Usage

```
ndb_import db_name file_name options
```

`ndb_import` requires two arguments. `db_name` is the name of the database where the table into which to import the data is found; `file_name` is the name of the CSV file from which to read the data; this must include the path to this file if it is not in the current directory. The name of the file must match that of the table; the file's extension, if any, is not taken into consideration. Options supported by `ndb_import` include those for specifying field separators, escapes, and line terminators, and are described later in this section. `ndb_import` must be able to connect to an NDB Cluster management server; for this reason, there must be an unused `[api]` slot in the cluster `config.ini` file.

To duplicate an existing table that uses a different storage engine, such as `InnoDB`, as an NDB table, use the `mysql` client to perform a `SELECT INTO OUTFILE` statement to export the existing table to a CSV file, then to execute a `CREATE TABLE LIKE` statement to create a new table having the same structure as the existing table, then perform `ALTER TABLE ... ENGINE=NDB` on the new table; after this, from the system shell, invoke `ndb_import` to load the data into the new NDB table. For example, an existing `InnoDB` table named `myinnodb_table` in a database named `myinnodb` can be exported into an NDB table named `myndb_table` in a database named `myndb` as shown here, assuming that you are already logged in as a MySQL user with the appropriate privileges:

1. In the `mysql` client:

```
mysql> USE myinnodb;
mysql> SELECT * INTO OUTFILE '/tmp/myndb_table.csv'
 > FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '\"' ESCAPED BY '\\'
 > LINES TERMINATED BY '\n'
 > FROM myinnodtable;

mysql> CREATE DATABASE myndb;

mysql> USE myndb;

mysql> CREATE TABLE myndb_table LIKE myinnodb.myinnodb_table;

mysql> ALTER TABLE myndb_table ENGINE=NDB;

mysql> EXIT;
Bye
shell>
```

Once the target database and table have been created, a running `mysqld` is no longer required. You can stop it using `mysqladmin shutdown` or another method before proceeding, if you wish.

2. In the system shell:

```
if you are not already in the MySQL bin directory:
shell> cd path-to-mysql-bin-dir

shell> ndb_import myndb /tmp/myndb_table.csv --fields-optionally-enclosed-by='\"' \
--fields-terminated-by="," --fields-escaped-by='\\'
```

The output should resemble what is shown here:

```
job-1 import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [running] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [success] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 imported 19984 rows in 0h0m9s at 2277 rows/s
jobs summary: defined: 1 run: 1 with success: 1 with failure: 0
shell>
```

Options that can be used with `ndb_import` are shown in the following table. Additional descriptions follow the table.

**Table 21.33 Command-line options used with the program `ndb_import`**

| Format                                 | Description                                                                                      | Added, Deprecated, or Removed                      |
|----------------------------------------|--------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--abort-on-error</code>          | Dump core on any fatal error; used for debugging                                                 | ADDED: NDB 7.6.2                                   |
| <code>--ai-increment=#</code>          | For table with hidden PK, specify autoincrement increment. See mysqld                            | ADDED: NDB 7.6.2                                   |
| <code>--ai-offset=#</code>             | For table with hidden PK, specify autoincrement offset. See mysqld                               | ADDED: NDB 7.6.2                                   |
| <code>--ai-prefetch-sz=#</code>        | For table with hidden PK, specify number of autoincrement values that are prefetched. See mysqld | ADDED: NDB 7.6.2                                   |
| <code>--character-sets-dir=path</code> | Directory containing character sets                                                              | ADDED: NDB 7.6.2                                   |
| <code>--connect-retries=#</code>       | Number of times to retry connection before giving up                                             | (Supported in all NDB releases based on MySQL 5.7) |

| <b>Format</b>                        | <b>Description</b>                                                                                                              | <b>Added, Deprecated, or Removed</b> |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| --connect-retry-delay=#              | Number of seconds to wait between attempts to contact management server                                                         | ADDED: NDB 7.6.2                     |
| --connect-string=connection-string,  | Same as --ndb-connectstring                                                                                                     | ADDED: NDB 7.6.2                     |
| -c                                   |                                                                                                                                 |                                      |
| --connections=#                      | Number of cluster connections to create                                                                                         | ADDED: NDB 7.6.2                     |
| --continue                           | When job fails, continue to next job                                                                                            | ADDED: NDB 7.6.2                     |
| --core-file                          | Write core file on error; used in debugging                                                                                     | ADDED: NDB 7.6.2                     |
| --db-workers#=                       | Number of threads, per data node, executing database operations                                                                 | ADDED: NDB 7.6.2                     |
| --defaults-extra-file=path           | Read given file after global files are read                                                                                     | ADDED: NDB 7.6.2                     |
| --defaults-file=path                 | Read default options from given file only                                                                                       | ADDED: NDB 7.6.2                     |
| --defaults-group-suffix=string       | Also read groups with concat(group, suffix)                                                                                     | ADDED: NDB 7.6.2                     |
| --errins-type=name                   | Error insert type, for testing purposes; use "list" to obtain all possible values                                               | ADDED: NDB 7.6.2                     |
| --errins-delay#=                     | Error insert delay in milliseconds; random variation is added                                                                   | ADDED: NDB 7.6.2                     |
| --fields-enclosed-by=char            | Same as FIELDS ENCLOSED BY option for LOAD DATA statements. For CSV input this is same as using --fields-optionally-enclosed-by | ADDED: NDB 7.6.2                     |
| --fields-escaped-by=name             | Same as FIELDS ESCAPED BY option for LOAD DATA statements                                                                       | ADDED: NDB 7.6.2                     |
| --fields-optionally-enclosed-by=char | Same as FIELDS OPTIONALLY ENCLOSED BY option for LOAD DATA statements                                                           | ADDED: NDB 7.6.2                     |
| --fields-terminated-by=char          | Same as FIELDS TERMINATED BY option for LOAD DATA statements                                                                    | ADDED: NDB 7.6.2                     |
| --help,                              | Display help text and exit                                                                                                      | ADDED: NDB 7.6.2                     |
| -?                                   |                                                                                                                                 |                                      |
| --idlesleep#=                        | Number of milliseconds to sleep waiting for more to do                                                                          | ADDED: NDB 7.6.2                     |
| --idlespin#=                         | Number of times to re-try before idlesleep                                                                                      | ADDED: NDB 7.6.2                     |

| Format                                 | Description                                                                                                                                                                                                                                    | Added, Deprecated, or Removed                      |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --ignore-lines=#                       | Ignore first # lines in input file. Used to skip a non-data header                                                                                                                                                                             | ADDED: NDB 7.6.2                                   |
| --input-type=name                      | Input type: random or csv                                                                                                                                                                                                                      | ADDED: NDB 7.6.2                                   |
| --input-workers=#                      | Number of threads processing input. Must be 2 or more if --input-type is csv                                                                                                                                                                   | ADDED: NDB 7.6.2                                   |
| --keep-state                           | State files (except non-empty *.rej files) are normally removed on job completion. Using this option causes all state files to be preserved instead                                                                                            | ADDED: NDB 7.6.4                                   |
| --lines-terminated-by=name             | Same as LINES TERMINATED BY option for LOAD DATA statements                                                                                                                                                                                    | ADDED: NDB 7.6.2                                   |
| --login-path=path                      | Read given path from login file                                                                                                                                                                                                                | ADDED: NDB 7.6.2                                   |
| --max-rows=#                           | Import only this number of input data rows; default is 0, which imports all rows                                                                                                                                                               | ADDED: NDB 7.6.2                                   |
| --monitor=#                            | Periodically print status of running job if something has changed (status, rejected rows, temporary errors). Value 0 disables. Value 1 prints any change seen. Higher values reduce status printing exponentially up to some pre-defined limit | ADDED: NDB 7.6.2                                   |
| --ndb-connectstring=connection-string, | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf                                                                                                 | ADDED: NDB 7.6.2                                   |
| -c                                     | Same as --ndb-connectstring                                                                                                                                                                                                                    | ADDED: NDB 7.6.2                                   |
| --ndb-mgmd-host=connection-string,     | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                                                                                                                                        | ADDED: NDB 7.6.2                                   |
| -c                                     | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable                                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-optimized-node-selection         | Run database operations as batches, in single transactions                                                                                                                                                                                     | ADDED: NDB 7.6.2                                   |
| --no-asynch                            | Do not read default options from any option file other than login file                                                                                                                                                                         | ADDED: NDB 7.6.2                                   |
| --no-defaults                          |                                                                                                                                                                                                                                                |                                                    |

| <b>Format</b>      | <b>Description</b>                                                                                                                                                                                                                                   | <b>Added, Deprecated, or Removed</b> |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| --no-hint          | Do not use distribution key hint to select data node (TC)                                                                                                                                                                                            | ADDED: NDB 7.6.2                     |
| --opbatch=#        | A db execution batch is a set of transactions and operations sent to NDB kernel. This option limits NDB operations (including blob operations) in a db execution batch. Therefore it also limits number of asynch transactions. Value 0 is not valid | ADDED: NDB 7.6.2                     |
| --opbytes=#        | Limit bytes in execution batch (default 0 = no limit)                                                                                                                                                                                                | ADDED: NDB 7.6.2                     |
| --output-type=name | Output type: ndb is default, null used for testing                                                                                                                                                                                                   | ADDED: NDB 7.6.2                     |
| --output-workers=# | Number of threads processing output or relaying database operations                                                                                                                                                                                  | ADDED: NDB 7.6.2                     |
| --pagesize=#       | Align I/O buffers to given size                                                                                                                                                                                                                      | ADDED: NDB 7.6.2                     |
| --pagecnt=#        | Size of I/O buffers as multiple of page size. CSV input worker allocates a double-sized buffer                                                                                                                                                       | ADDED: NDB 7.6.2                     |
| --polltimeout=#    | Timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or error occurs                                                                                                                           | ADDED: NDB 7.6.2                     |
| --print-defaults   | Print program argument list and exit                                                                                                                                                                                                                 | ADDED: NDB 7.6.2                     |
| --rejects=#        | Limit number of rejected rows (rows with permanent error) in data load. Default is 0 which means that any rejected row causes a fatal error. The row exceeding the limit is also added to *.rej                                                      | ADDED: NDB 7.6.2                     |
| --resume           | If job aborted (temporary error, user interrupt), resume with rows not yet processed                                                                                                                                                                 | ADDED: NDB 7.6.2                     |
| --rowbatch=#       | Limit rows in row queues (default 0 = no limit); must be 1 or more if --input-type is random                                                                                                                                                         | ADDED: NDB 7.6.2                     |
| --rowbytes=#       | Limit bytes in row queues (0 = no limit)                                                                                                                                                                                                             | ADDED: NDB 7.6.2                     |
| --state-dir=name   | Where to write state files; current directory is default                                                                                                                                                                                             | ADDED: NDB 7.6.2                     |
| --stats            | Save performance related options and internal statistics in *.sto and *.stt files. These files are kept on successful completion even if --keep-state is not used                                                                                    | ADDED: NDB 7.6.4                     |

| Format           | Description                                                                                                                                                                              | Added, Deprecated, or Removed |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| --tempdelay=#    | Number of milliseconds to sleep between temporary errors                                                                                                                                 | ADDED: NDB 7.6.2              |
| --temperrors=#   | Number of times a transaction can fail due to a temporary error, per execution batch; 0 means any temporary error is fatal. Such errors do not cause any rows to be written to .rej file | ADDED: NDB 7.6.2              |
| --usage,<br>-?   | Display help text and exit; same as --help                                                                                                                                               | ADDED: NDB 7.6.2              |
| --verbose,<br>-v | Enable verbose output                                                                                                                                                                    | ADDED: NDB 7.6.2              |
| --version,<br>-V | Display version information and exit                                                                                                                                                     | ADDED: NDB 7.6.2              |

- `--abort-on-error`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--abort-on-error</code> |
| Introduced          | 5.7.18-ndb-7.6.2              |
| Type                | Boolean                       |
| Default Value       | <code>FALSE</code>            |

Dump core on any fatal error; used for debugging only.

- `--ai-increment=#`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--ai-increment=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2              |
| Type                | Integer                       |
| Default Value       | <code>1</code>                |
| Minimum Value       | <code>1</code>                |
| Maximum Value       | <code>4294967295</code>       |

For a table with a hidden primary key, specify the autoincrement increment, like the `auto_increment_increment` system variable does in the MySQL Server.

- `--ai-offset=#`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--ai-offset=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2           |
| Type                | Integer                    |
| Default Value       | <code>1</code>             |
| Minimum Value       | <code>1</code>             |
| Maximum Value       | <code>4294967295</code>    |

For a table with hidden primary key, specify the autoincrement offset. Similar to the `auto_increment_offset` system variable.

- `--ai-prefetch-sz=#`

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | <code>--ai-prefetch-sz=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2                |
| Type                | Integer                         |
| Default Value       | 1024                            |
| Minimum Value       | 1                               |
| Maximum Value       | 4294967295                      |

For a table with a hidden primary key, specify the number of autoincrement values that are prefetched. Behaves like the `ndb_autoincrement_prefetch_sz` system variable does in the MySQL Server.

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
| Introduced          | 5.7.18-ndb-7.6.2                       |

Directory containing character sets.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | 12                               |
| Minimum Value       | 0                                |
| Maximum Value       | 12                               |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2                     |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 5                                    |

Number of seconds to wait between attempts to contact management server.

- `--connections=#`

|                     |                              |
|---------------------|------------------------------|
| Command-Line Format | <code>--connections=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2             |
| Type                | Integer                      |
| Default Value       | 1                            |
| Minimum Value       | 1                            |
| Maximum Value       | 4294967295                   |

Number of cluster connections to create.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Introduced          | 5.7.18-ndb-7.6.2                                |
| Type                | String                                          |
| Default Value       | [none]                                          |

Same as `--ndb-connectstring`.

- `--continue`

|                     |                         |
|---------------------|-------------------------|
| Command-Line Format | <code>--continue</code> |
| Introduced          | 5.7.18-ndb-7.6.2        |
| Type                | Boolean                 |
| Default Value       | FALSE                   |

When a job fails, continue to the next job.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
| Introduced          | 5.7.18-ndb-7.6.2         |

Write core file on error; used in debugging.

- `--db-workers=#`

|                                                        |                             |
|--------------------------------------------------------|-----------------------------|
| Command-Line Format                                    | <code>--db-workers=#</code> |
| Introduced                                             | 5.7.18-ndb-7.6.2            |
| Type                                                   | Integer                     |
| Default Value (≥ 5.7.20-ndb-7.6.4)                     | 4                           |
| Default Value (≥ 5.7.18-ndb-7.6.2, ≤ 5.7.18-ndb-7.6.3) | 1                           |
| Minimum Value                                          | 1                           |
| Maximum Value                                          | 4294967295                  |

Number of threads, per data node, executing database operations.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Introduced          | 5.7.18-ndb-7.6.2                        |
| Type                | String                                  |
| Default Value       | [none]                                  |

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Introduced          | 5.7.18-ndb-7.6.2                  |

|               |        |
|---------------|--------|
| Type          | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Introduced          | 5.7.18-ndb-7.6.2                            |
| Type                | String                                      |
| Default Value       | [none]                                      |

Also read groups with concat(group, suffix).

- `--errins-type=name`

|                     |                                                                                                                 |
|---------------------|-----------------------------------------------------------------------------------------------------------------|
| Command-Line Format | <code>--errins-type=name</code>                                                                                 |
| Introduced          | 5.7.18-ndb-7.6.2                                                                                                |
| Type                | Enumeration                                                                                                     |
| Default Value       | [none]                                                                                                          |
| Valid Values        | <code>stopjob</code><br><code>stopall</code><br><code>sighup</code><br><code>sigint</code><br><code>list</code> |

Error insert type; use `list` as the `name` value to obtain all possible values. This option is used for testing purposes only.

- `--errins-delay=#`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--errins-delay=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2              |
| Type                | Integer                       |
| Default Value       | 1000                          |
| Minimum Value       | 0                             |
| Maximum Value       | 4294967295                    |
| Unit                | ms                            |

Error insert delay in milliseconds; random variation is added. This option is used for testing purposes only.

- `--fields-enclosed-by=char`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--fields-enclosed-by=char</code> |
| Introduced          | 5.7.18-ndb-7.6.2                       |
| Type                | String                                 |

|               |        |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

This works in the same way as the `FIELDS ENCLOSED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as quoting field values. For CSV input, this is the same as `--fields-optionally-enclosed-by`.

- `--fields-escaped-by=name`

|                     |                                       |
|---------------------|---------------------------------------|
| Command-Line Format | <code>--fields-escaped-by=name</code> |
| Introduced          | 5.7.18-ndb-7.6.2                      |
| Type                | String                                |
| Default Value       | \                                     |

Specify an escape character in the same way as the `FIELDS ESCAPED BY` option does for the SQL `LOAD DATA` statement.

- `--fields-optionally-enclosed-by=char`

|                     |                                                   |
|---------------------|---------------------------------------------------|
| Command-Line Format | <code>--fields-optionally-enclosed-by=char</code> |
| Introduced          | 5.7.18-ndb-7.6.2                                  |
| Type                | String                                            |
| Default Value       | [none]                                            |

This works in the same way as the `FIELDS OPTIONALLY ENCLOSED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as optionally quoting field values. For CSV input, this is the same as `--fields-enclosed-by`.

- `--fields-terminated-by=char`

|                     |                                          |
|---------------------|------------------------------------------|
| Command-Line Format | <code>--fields-terminated-by=char</code> |
| Introduced          | 5.7.18-ndb-7.6.2                         |
| Type                | String                                   |
| Default Value       | \t                                       |

This works in the same way as the `FIELDS TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as the field separator.

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
| Introduced          | 5.7.18-ndb-7.6.2    |

Display help text and exit.

- `--idlesleep=#`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--idlesleep=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2           |
| Type                | Integer                    |
| Default Value       | 1                          |
| Minimum Value       | 1                          |
| Maximum Value       | 4294967295                 |
| Unit                | ms                         |

Number of milliseconds to sleep waiting for more work to perform.

- `--idleSpin=#`

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>--idleSpin=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2          |
| Type                | Integer                   |
| Default Value       | 0                         |
| Minimum Value       | 0                         |
| Maximum Value       | 4294967295                |

Number of times to retry before sleeping.

- `--ignoreLines=#`

|                     |                              |
|---------------------|------------------------------|
| Command-Line Format | <code>--ignoreLines=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2             |
| Type                | Integer                      |
| Default Value       | 0                            |
| Minimum Value       | 0                            |
| Maximum Value       | 4294967295                   |

Cause `ndb_import` to ignore the first # lines of the input file. This can be employed to skip a file header that does not contain any data.

- `--inputType=name`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--inputType=name</code>           |
| Introduced          | 5.7.18-ndb-7.6.2                        |
| Type                | Enumeration                             |
| Default Value       | <code>csv</code>                        |
| Valid Values        | <code>random</code><br><code>csv</code> |

Set the type of input type. The default is `csv`; `random` is intended for testing purposes only. .

- `--inputWorkers=#`

|                                                        |                               |
|--------------------------------------------------------|-------------------------------|
| Command-Line Format                                    | <code>--inputWorkers=#</code> |
| Introduced                                             | 5.7.18-ndb-7.6.2              |
| Type                                                   | Integer                       |
| Default Value (≥ 5.7.20-ndb-7.6.4)                     | 4                             |
| Default Value (≥ 5.7.18-ndb-7.6.2, ≤ 5.7.18-ndb-7.6.3) | 2                             |
| Minimum Value                                          | 1                             |
| Maximum Value                                          | 4294967295                    |

Set the number of threads processing input.

- `--keep-state`

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>--keep-state</code> |
| Introduced          | 5.7.20-ndb-7.6.4          |
| Type                | Boolean                   |
| Default Value       | <code>false</code>        |

By default, `ndb_import` removes all state files (except non-empty `*.rej` files) when it completes a job. Specify this option (nor argument is required) to force the program to retain all state files instead.

- `--lines-terminated-by=name`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--lines-terminated-by=name</code> |
| Introduced          | 5.7.18-ndb-7.6.2                        |
| Type                | String                                  |
| Default Value       | <code>\n</code>                         |

This works in the same way as the `LINES TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as end-of-line.

- `--login-path`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Introduced          | 5.7.18-ndb-7.6.2               |
| Type                | String                         |
| Default Value       | <code>[none]</code>            |

Read given path from login file.

- `--log-level=#`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--log-level=#</code> |
| Type                | Integer                    |
| Default Value       | <code>0</code>             |
| Minimum Value       | <code>0</code>             |
| Maximum Value       | <code>2</code>             |

Performs internal logging at the given level. This option is intended primarily for internal and development use.

In debug builds of NDB only, the logging level can be set using this option to a maximum of 4.

- `--max-rows#=`

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>--max-rows#=</code> |
| Introduced          | 5.7.18-ndb-7.6.2          |
| Type                | Integer                   |
| Default Value       | <code>0</code>            |
| Minimum Value       | <code>0</code>            |
| Maximum Value       | <code>4294967295</code>   |

|      |                    |
|------|--------------------|
| Unit | <code>bytes</code> |
|------|--------------------|

Import only this number of input data rows; the default is 0, which imports all rows.

- `--monitor=#`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--monitor=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2         |
| Type                | Integer                  |
| Default Value       | <code>2</code>           |
| Minimum Value       | <code>0</code>           |
| Maximum Value       | <code>4294967295</code>  |
| Unit                | <code>bytes</code>       |

Periodically print the status of a running job if something has changed (status, rejected rows, temporary errors). Set to 0 to disable this reporting. Setting to 1 prints any change that is seen. Higher values reduce the frequency of this status reporting.

- `--ndb-connectstring`

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Introduced          | 5.7.18-ndb-7.6.2                                   |
| Type                | String                                             |
| Default Value       | <code>[none]</code>                                |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Introduced          | 5.7.18-ndb-7.6.2                               |
| Type                | String                                         |
| Default Value       | <code>[none]</code>                            |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2            |
| Type                | Integer                     |
| Default Value       | <code>[none]</code>         |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-asynch`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--no-asynch</code> |
| Introduced          | 5.7.18-ndb-7.6.2         |
| Type                | Boolean                  |
| Default Value       | <code>FALSE</code>       |

Run database operations as batches, in single transactions.

- `--no-defaults`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
| Introduced          | 5.7.18-ndb-7.6.2           |

Do not read default options from any option file other than login file.

- `--no-hint`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--no-hint</code> |
| Introduced          | 5.7.18-ndb-7.6.2       |
| Type                | Boolean                |
| Default Value       | <code>FALSE</code>     |

Do not use distribution key hinting to select a data node.

- `--opbatch=#`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--opbatch=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2         |
| Type                | Integer                  |
| Default Value       | <code>256</code>         |
| Minimum Value       | <code>1</code>           |
| Maximum Value       | <code>4294967295</code>  |
| Unit                | <code>bytes</code>       |

Set a limit on the number of operations (including blob operations), and thus the number of asynchronous transactions, per execution batch.

- `--opbytes=#`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--opbytes=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2         |
| Type                | Integer                  |
| Default Value       | <code>0</code>           |
| Minimum Value       | <code>0</code>           |
| Maximum Value       | <code>4294967295</code>  |
| Unit                | <code>bytes</code>       |

Set a limit on the number of bytes per execution batch. Use 0 for no limit.

- `--output-type=name`

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | <code>--output-type=name</code> |
|---------------------|---------------------------------|

|               |                  |
|---------------|------------------|
| Introduced    | 5.7.18-ndb-7.6.2 |
| Type          | Enumeration      |
| Default Value | ndb              |
| Valid Values  | null             |

Set the output type. `ndb` is the default. `null` is used only for testing.

- `--output-workers=#`

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | <code>--output-workers=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2                |
| Type                | Integer                         |
| Default Value       | 2                               |
| Minimum Value       | 1                               |
| Maximum Value       | 4294967295                      |

Set the number of threads processing output or relaying database operations.

- `--pagesize=#`

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>--pagesize=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2          |
| Type                | Integer                   |
| Default Value       | 4096                      |
| Minimum Value       | 1                         |
| Maximum Value       | 4294967295                |
| Unit                | bytes                     |

Align I/O buffers to the given size.

- `--pagecnt=#`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--pagecnt=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2         |
| Type                | Integer                  |
| Default Value       | 64                       |
| Minimum Value       | 1                        |
| Maximum Value       | 4294967295               |

Set the size of I/O buffers as multiple of page size. The CSV input worker allocates buffer that is doubled in size.

- `--polltimeout=#`

|                     |                              |
|---------------------|------------------------------|
| Command-Line Format | <code>--polltimeout=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2             |
| Type                | Integer                      |
| Default Value       | 1000                         |
| Minimum Value       | 1                            |

|               |            |
|---------------|------------|
| Maximum Value | 4294967295 |
| Unit          | ms         |

Set a timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or until an error occurs.

- `--print-defaults`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
| Introduced          | 5.7.18-ndb-7.6.2              |

Print program argument list and exit.

- `--rejects=#`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--rejects=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2         |
| Type                | Integer                  |
| Default Value       | 0                        |
| Minimum Value       | 0                        |
| Maximum Value       | 4294967295               |

Limit the number of rejected rows (rows with permanent errors) in the data load. The default is 0, which means that any rejected row causes a fatal error. Any rows causing the limit to be exceeded are added to the `.rej` file.

The limit imposed by this option is effective for the duration of the current run. A run restarted using `--resume` is considered a “new” run for this purpose.

- `--resume`

|                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>--resume</code> |
| Introduced          | 5.7.18-ndb-7.6.2      |
| Type                | Boolean               |
| Default Value       | <code>FALSE</code>    |

If a job is aborted (due to a temporary db error or when interrupted by the user), resume with any rows not yet processed.

- `--rowbatch=#`

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>--rowbatch=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2          |
| Type                | Integer                   |
| Default Value       | 0                         |
| Minimum Value       | 0                         |
| Maximum Value       | 4294967295                |
| Unit                | rows                      |

Set a limit on the number of rows per row queue. Use 0 for no limit.

- `--rowbytes=#`

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>--rowbytes=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2          |
| Type                | Integer                   |
| Default Value       | <code>262144</code>       |
| Minimum Value       | <code>0</code>            |
| Maximum Value       | <code>4294967295</code>   |
| Unit                | <code>bytes</code>        |

Set a limit on the number of bytes per row queue. Use 0 for no limit.

- `--stats`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--stats</code> |
| Introduced          | 5.7.20-ndb-7.6.4     |
| Type                | Boolean              |
| Default Value       | <code>false</code>   |

Save information about options related to performance and other internal statistics in files named `*.sto` and `*.stt`. These files are always kept on successful completion (even if `--keep-state` is not also specified).

- `--state-dir=name`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--state-dir=name</code> |
| Introduced          | 5.7.18-ndb-7.6.2              |
| Type                | String                        |
| Default Value       | <code>.</code>                |

Where to write the state files (`tbl_name.map`, `tbl_name.rej`, `tbl_name.res`, and `tbl_name.stt`) produced by a run of the program; the default is the current directory.

- `--tempdelay=#`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--tempdelay=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2           |
| Type                | Integer                    |
| Default Value       | <code>10</code>            |
| Minimum Value       | <code>0</code>             |
| Maximum Value       | <code>4294967295</code>    |
| Unit                | <code>ms</code>            |

Number of milliseconds to sleep between temporary errors.

- `--temperrors=#`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--temperrors=#</code> |
| Introduced          | 5.7.18-ndb-7.6.2            |
| Type                | Integer                     |
| Default Value       | <code>0</code>              |

|               |            |
|---------------|------------|
| Minimum Value | 0          |
| Maximum Value | 4294967295 |

Number of times a transaction can fail due to a temporary error, per execution batch. The default is 0, which means that any temporary error is fatal. Temporary errors do not cause any rows to be added to the `.rej` file.

- `--usage`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
| Introduced          | 5.7.18-ndb-7.6.2     |

Display help text and exit; same as `--help`.

- `--verbose`, `-v`

|                                                                   |                        |
|-------------------------------------------------------------------|------------------------|
| Command-Line Format                                               | <code>--verbose</code> |
| Introduced                                                        | 5.7.18-ndb-7.6.2       |
| Type ( $\geq$ 5.7.20-ndb-7.6.4)                                   | Boolean                |
| Type ( $\geq$ 5.7.18-ndb-7.6.2, $\leq$ 5.7.18-ndb-7.6.3)          | Integer                |
| Default Value ( $\geq$ 5.7.20-ndb-7.6.4)                          | <code>false</code>     |
| Default Value ( $\geq$ 5.7.18-ndb-7.6.2, $\leq$ 5.7.18-ndb-7.6.3) | 0                      |
| Minimum Value                                                     | 0                      |
| Maximum Value                                                     | 2                      |

NDB 7.6.4 and later: Enable verbose output.

Previously, this option controlled the internal logging level for debugging messages. In NDB 7.6.4 and later, use the `--log-level` option for this purpose instead.

- `--version`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
| Introduced          | 5.7.18-ndb-7.6.2       |

Display version information and exit.

As with `LOAD DATA`, options for field and line formatting much match those used to create the CSV file, whether this was done using `SELECT INTO ... OUTFILE`, or by some other means. There is no equivalent to the `LOAD DATA` statement `STARTING WITH` option.

`ndb_import` was added in NDB 7.6.2.

## 21.4.15 ndb\_index\_stat — NDB Index Statistics Utility

`ndb_index_stat` provides per-fragment statistical information about indexes on `NDB` tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

## Usage

To obtain basic index statistics about a given NDB table, invoke `ndb_index_stat` as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the `--database` (`-d`) option:

```
ndb_index_stat table -d database
```

In this example, we use `ndb_index_stat` to obtain such information about an NDB table named `mytable` in the `test` database:

```
shell> ndb_index_stat -d test mytable
table:City index:PRIMARY fragCount:2
sampleVersion:3 loadTime:1399585986 sampleCount:1994 keyBytes:7976
query cache: valid:1 sampleCount:1994 totalBytes:27916
times in ms: save: 7.133 sort: 1.974 sort per sample: 0.000

NDBT_ProgramExit: 0 - OK
```

`sampleVersion` is the version number of the cache from which the statistics data is taken. Running `ndb_index_stat` with the `--update` option causes `sampleVersion` to be incremented.

`loadTime` shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

`sampleCount` is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as `fragCount`).

`sampleCount` can be compared with the cardinality of `SHOW INDEX` or `INFORMATION_SCHEMA.STATISTICS`, although the latter two provide a view of the table as a whole, while `ndb_index_stat` provides a per-fragment average.

`keyBytes` is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so `keyBytes` can be calculated in this case as shown here:

```
keyBytes = sampleCount * (4 bytes per index) = 1994 * 4 = 7976
```

This information can also be obtained using the corresponding column definitions from `INFORMATION_SCHEMA.COLUMNS` (this requires a MySQL Server and a MySQL client application).

`totalBytes` is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of `ndb_index_stat`.

The `--verbose` option provides some additional output, as shown here:

```
shell> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected

NDBT_ProgramExit: 0 - OK

shell>
```

If the only output from the program is `NDBT_ProgramExit: 0 - OK`, this may indicate that no statistics yet exist. To force them to be created (or updated if they already exist), invoke `ndb_index_stat` with the `--update` option, or execute `ANALYZE TABLE` on the table in the `mysql` client.

## Options

The following table includes options that are specific to the NDB Cluster `ndb_index_stat` utility. Additional descriptions are listed following the table.

**Table 21.34 Command-line options used with the program `ndb_index_stat`**

| Format                                              | Description                                                                                                                                                                                | Added, Deprecated, or Removed                      |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--character-sets-dir=path</code>              | Directory containing character sets                                                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retries=#</code>                    | Number of times to retry connection before giving up                                                                                                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retry-delay=#</code>                | Number of seconds to wait between attempts to contact management server                                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-string=connection-string,</code>    | Same as <code>--ndb-connectstring</code>                                                                                                                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     |                                                                                                                                                                                            |                                                    |
| <code>--core-file</code>                            | Write core file on error; used in debugging                                                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--database=name,</code>                       | Name of database containing table                                                                                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-d</code>                                     |                                                                                                                                                                                            |                                                    |
| <code>--defaults-extra-file=path</code>             | Read given file after global files are read                                                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-file=path</code>                   | Read default options from given file only                                                                                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-group-suffix=string</code>         | Also read groups with concat(group, suffix)                                                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--delete</code>                               | Delete index statistics for table, stopping any auto-update previously configured                                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--dump</code>                                 | Print query cache                                                                                                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--help,</code>                                | Display help text and exit                                                                                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-?</code>                                     |                                                                                                                                                                                            |                                                    |
| <code>--login-path=path</code>                      | Read given path from login file                                                                                                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--loops=#</code>                              | Set the number of times to perform given command; default is 0                                                                                                                             | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--ndb-connectstring=connection-string,</code> | Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: "[nodeid=id;]<br>[host=]hostname[:port]". Overrides entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code> | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     |                                                                                                                                                                                            |                                                    |
| <code>--ndb-mgmd-host=connection-string,</code>     | Same as <code>--ndb-connectstring</code>                                                                                                                                                   | (Supported in all NDB releases based on MySQL 5.7) |

| Format                                      | Description                                                                                                                             | Added, Deprecated, or Removed                      |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>-c</code>                             |                                                                                                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--ndb-nodeid=#</code>                 | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions.<br>Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--no-defaults</code>                  | Do not read default options from any option file other than login file                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--print-defaults</code>               | Print program argument list and exit                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--query=#</code>                      | Perform random range queries on first key attr (must be int unsigned)                                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--sys-drop</code>                     | Drop any statistics tables and events in NDB kernel (all statistics are lost)                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--sys-create</code>                   | Create all statistics tables and events in NDB kernel, if none of them already exist                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--sys-create-if-not-exist</code>      | Create any statistics tables and events in NDB kernel that do not already exist                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--sys-create-if-not-valid</code>      | Create any statistics tables or events that do not already exist in the NDB kernel, after dropping any that are invalid                 | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--sys-check</code>                    | Verify that NDB system index statistics and event tables exist                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--sys-skip-tables</code>              | Do not apply sys-* options to tables                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--sys-skip-events</code>              | Do not apply sys-* options to events                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--update</code>                       | Update index statistics for table, restarting any auto-update previously configured                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--usage,</code><br><code>-?</code>    | Display help text and exit; same as --help                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--verbose,</code><br><code>-v</code>  | Turn on verbose output                                                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--version,</code><br><code>-V</code>  | Display version information and exit                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | 12                               |
| Minimum Value       | 0                                |
| Maximum Value       | 12                               |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 5                                    |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | [none]                                          |

Same as `--ndb-connectstring`.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database=name, -d name`

|                     |                              |
|---------------------|------------------------------|
| Command-Line Format | <code>--database=name</code> |
| Type                | String                       |
| Default Value       | [none]                       |
| Minimum Value       |                              |
| Maximum Value       |                              |

The name of the database that contains the table being queried.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |

|               |                     |
|---------------|---------------------|
| Default Value | <code>[none]</code> |
|---------------|---------------------|

Read given file after global files are read.

- **--defaults-file**

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | <code>[none]</code>               |

Read default options from given file only.

- **--defaults-group-suffix**

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | <code>[none]</code>                         |

Also read groups with concat(group, suffix).

- **--delete**

|                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>--delete</code> |
| Type                | Boolean               |
| Default Value       | <code>false</code>    |
| Minimum Value       |                       |
| Maximum Value       |                       |

Delete the index statistics for the given table, stopping any auto-update that was previously configured.

- **--dump**

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--dump</code> |
| Type                | Boolean             |
| Default Value       | <code>false</code>  |
| Minimum Value       |                     |
| Maximum Value       |                     |

Dump the contents of the query cache.

- **--help**

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- **--login-path**

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type                | String                         |
| Default Value       | <code>[none]</code>            |

Read given path from login file.

- `--loops=#`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--loops=#</code> |
| Type                | Numeric                |
| Default Value       | 0                      |
| Minimum Value       | 0                      |
| Maximum Value       | <code>MAX_INT</code>   |

Repeat commands this number of times (for use in testing).

- `--ndb-connectstring`

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |
| Default Value       | [none]                                             |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | [none]                                         |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | [none]                      |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

- `--query=#`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--query=#</code> |
| Type                | Numeric                |
| Default Value       | 0                      |
| Minimum Value       | 0                      |
| Maximum Value       | <code>MAX_INT</code>   |

Perform random range queries on first key attribute (must be int unsigned).

- `--sys-drop`

|                     |                         |
|---------------------|-------------------------|
| Command-Line Format | <code>--sys-drop</code> |
| Type                | Boolean                 |
| Default Value       | <code>false</code>      |
| Minimum Value       |                         |
| Maximum Value       |                         |

Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost.*

- `--sys-create`

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>--sys-create</code> |
| Type                | Boolean                   |
| Default Value       | <code>false</code>        |
| Minimum Value       |                           |
| Maximum Value       |                           |

Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

- `sys-create-if-not-exist`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--sys-create-if-not-exist</code> |
| Type                | Boolean                                |
| Default Value       | <code>false</code>                     |
| Minimum Value       |                                        |
| Maximum Value       |                                        |

Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

- `--sys-create-if-not-valid`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--sys-create-if-not-valid</code> |
| Type                | Boolean                                |
| Default Value       | <code>false</code>                     |
| Minimum Value       |                                        |

|               |  |
|---------------|--|
| Maximum Value |  |
|---------------|--|

Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

- `--sys-check`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--sys-check</code> |
| Type                | Boolean                  |
| Default Value       | <code>false</code>       |
| Minimum Value       |                          |
| Maximum Value       |                          |

Verify that all required system statistics tables and events exist in the NDB kernel.

- `--sys-skip-tables`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--sys-skip-tables</code> |
| Type                | Boolean                        |
| Default Value       | <code>false</code>             |
| Minimum Value       |                                |
| Maximum Value       |                                |

Do not apply any `--sys-*` options to any statistics tables.

- `--sys-skip-events`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--sys-skip-events</code> |
| Type                | Boolean                        |
| Default Value       | <code>false</code>             |
| Minimum Value       |                                |
| Maximum Value       |                                |

Do not apply any `--sys-*` options to any events.

- `--update`

|                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>--update</code> |
| Type                | Boolean               |
| Default Value       | <code>false</code>    |
| Minimum Value       |                       |
| Maximum Value       |                       |

Update the index statistics for the given table, and restart any auto-update that was previously configured.

- `--usage`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--verbose`

|                     |           |
|---------------------|-----------|
| Command-Line Format | --verbose |
| Type                | Boolean   |
| Default Value       | false     |
| Minimum Value       |           |
| Maximum Value       |           |

Turn on verbose output.

- --version

|                     |           |
|---------------------|-----------|
| Command-Line Format | --version |
|---------------------|-----------|

Display version information and exit.

**ndb\_index\_stat system options.** The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see [ndb\\_index\\_stat statistics options](#)).

- --sys-drop
- --sys-create
- --sys-create-if-not-exist
- --sys-create-if-not-valid
- --sys-check
- --sys-skip-tables
- --sys-skip-events

**ndb\_index\_stat statistics options.** The options listed here are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see [ndb\\_index\\_stat system options](#)).

- --database
- --delete
- --update
- --dump
- --query

## 21.4.16 ndb\_move\_data — NDB Data Copy Utility

`ndb_move_data` copies data from one NDB table to another.

### Usage

The program is invoked with the names of the source and target tables; either or both of these may be qualified optionally with the database name. Both tables must use the NDB storage engine.

```
ndb_move_data options source target
```

Options that can be used with `ndb_move_data` are shown in the following table. Additional descriptions follow the table.

**Table 21.35 Command-line options used with the program `ndb_move_data`**

| <b>Format</b>                                       | <b>Description</b>                                                                                             | <b>Added, Deprecated, or Removed</b>               |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--abort-on-error</code>                       | Dump core on permanent error (debug option)                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--character-sets-dir=name</code>              | Directory where character sets are                                                                             | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retries=#</code>                    | Number of times to retry connection before giving up                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retry-delay=#</code>                | Number of seconds to wait between attempts to contact management server                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-string=connection-string,</code>    | Same as <code>--ndb-connectstring</code>                                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     |                                                                                                                |                                                    |
| <code>--core-file</code>                            | Write core file on error; used in debugging                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--database=dbname,</code>                     | Name of database in which table is found                                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-d</code>                                     |                                                                                                                |                                                    |
| <code>--defaults-extra-file=path</code>             | Read given file after global files are read                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-file=path</code>                   | Read default options from given file only                                                                      | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-group-suffix=string</code>         | Also read groups with concat(group, suffix)                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--drop-source</code>                          | Drop source table after all rows have been moved                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--error-insert</code>                         | Insert random temporary errors (testing option)                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--exclude-missing-columns</code>              | Ignore extra columns in source or target table                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--help,</code>                                | Display help text and exit                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-?</code>                                     |                                                                                                                |                                                    |
| <code>--login-path=path</code>                      | Read given path from login file                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--lossy-conversions,</code>                   | Allow attribute data to be truncated when converted to smaller type                                            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-l</code>                                     |                                                                                                                |                                                    |
| <code>--ndb-connectstring=connection-string,</code> | Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: "[nodeid=id;]<br>[host=]hostname[:port]". | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     | Overrides entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code>                                    |                                                    |
| <code>--ndb-mgmd-host=connection-string,</code>     | Same as <code>--ndb-connectstring</code>                                                                       | (Supported in all NDB releases based on MySQL 5.7) |

| Format                                      | Description                                                                                                                             | Added, Deprecated, or Removed                      |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>-c</code>                             |                                                                                                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--ndb-nodeid=#</code>                 | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions.<br>Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--no-defaults</code>                  | Do not read default options from any option file other than login file                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--print-defaults</code>               | Print program argument list and exit                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--promote-attributes</code> ,         | Allow attribute data to be converted to larger type                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-A</code>                             |                                                                                                                                         |                                                    |
| <code>--staging-tries=x[,y[,z]]</code>      | Specify tries on temporary errors; format is x[y,z] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms)                  | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--usage</code> ,                      | Display help text and exit; same as --help                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-?</code>                             |                                                                                                                                         |                                                    |
| <code>--verbose</code>                      | Enable verbose messages                                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--version</code> ,                    | Display version information and exit                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-V</code>                             |                                                                                                                                         |                                                    |

- `--abort-on-error`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--abort-on-error</code> |
| Type                | Boolean                       |
| Default Value       | <code>FALSE</code>            |

Dump core on permanent error (debug option).

- `--character-sets-dir=name`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=name</code> |
| Type                | String                                 |
| Default Value       | <code>[none]</code>                    |

Directory where character sets are.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | <code>5</code>                       |
| Minimum Value       | <code>0</code>                       |

|               |   |
|---------------|---|
| Maximum Value | 5 |
|---------------|---|

Number of seconds to wait between attempts to contact management server.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | 12                               |
| Minimum Value       | 0                                |
| Maximum Value       | 12                               |

Number of times to retry connection before giving up.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | [none]                                          |

Same as `--ndb-connectstring`.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database=dbname, -d`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--database=dbname</code> |
| Type                | String                         |
| Default Value       | TEST_DB                        |

Name of the database in which the table is found.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | [none]                                  |

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | [none]                            |

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
|---------------------|---------------------------------------------|

|               |        |
|---------------|--------|
| Type          | String |
| Default Value | [none] |

Also read groups with concat(group, suffix).

- `--drop-source`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--drop-source</code> |
| Type                | Boolean                    |
| Default Value       | <code>FALSE</code>         |

Drop source table after all rows have been moved.

- `--error-insert`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--error-insert</code> |
| Type                | Boolean                     |
| Default Value       | <code>FALSE</code>          |

Insert random temporary errors (testing option).

- `--exclude-missing-columns`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--exclude-missing-columns</code> |
| Type                | Boolean                                |
| Default Value       | <code>FALSE</code>                     |

Ignore extra columns in source or target table.

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type                | String                         |
| Default Value       | [none]                         |

Read given path from login file.

- `--lossy-conversions, -l`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--lossy-conversions</code> |
| Type                | Boolean                          |
| Default Value       | <code>FALSE</code>               |

Allow attribute data to be truncated when converted to a smaller type.

- `--ndb-connectstring`

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |

|               |                     |
|---------------|---------------------|
| Default Value | <code>[none]</code> |
|---------------|---------------------|

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | <code>[none]</code>                            |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | <code>[none]</code>         |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--promote-attributes, -A`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--promote-attributes</code> |
| Type                | Boolean                           |
| Default Value       | <code>FALSE</code>                |

Allow attribute data to be converted to a larger type.

- `--staging-tries=x[,y[,z]]`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--staging-tries=x[,y[,z]]</code> |
| Type                | String                                 |
| Default Value       | <code>0,1000,60000</code>              |

Specify tries on temporary errors. Format is `x[,y[,z]]` where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms).

- [--usage](#)

|                     |                         |
|---------------------|-------------------------|
| Command-Line Format | <a href="#">--usage</a> |
|---------------------|-------------------------|

Display help text and exit; same as [--help](#).

- [--verbose](#)

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <a href="#">--verbose</a> |
| Type                | Boolean                   |
| Default Value       | <a href="#">FALSE</a>     |

Enable verbose messages.

- [--version](#)

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <a href="#">--version</a> |
|---------------------|---------------------------|

Display version information and exit.

## 21.4.17 ndb\_perror — Obtain NDB Error Message Information

[ndb\\_perror](#) shows information about an NDB error, given its error code. This includes the error message, the type of error, and whether the error is permanent or temporary. Added to the MySQL NDB Cluster distribution in NDB 7.6.4, it is intended as a drop-in replacement for  [perror --ndb](#).

### Usage

```
ndb_perror [options] error_code
```

[ndb\\_perror](#) does not need to access a running NDB Cluster, or any nodes (including SQL nodes). To view information about a given NDB error, invoke the program, using the error code as an argument, like this:

```
shell> ndb_perror 323
NDB error code 323: Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

To display only the error message, invoke [ndb\\_perror](#) with the [--silent](#) option (short form [-s](#)), as shown here:

```
shell> ndb_perror -s 323
Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

Like [perror](#), [ndb\\_perror](#) accepts multiple error codes:

```
shell> ndb_perror 321 1001
NDB error code 321: Invalid nodegroup id: Permanent error: Application error
NDB error code 1001: Illegal connect string
```

Additional program options for [ndb\\_perror](#) are described later in this section.

[ndb\\_perror](#) replaces [perror --ndb](#), which is deprecated as of NDB 7.6.4 and subject to removal in a future release of MySQL NDB Cluster. To make substitution easier in scripts and other applications that might depend on [perror](#) for obtaining NDB error information, [ndb\\_perror](#) supports its own “dummy” [--ndb](#) option, which does nothing.

The following table includes all options that are specific to the NDB Cluster program [ndb\\_perror](#). Additional descriptions follow the table.

**Table 21.36 Command-line options used with the program `ndb_perror`**

| Format                                      | Description                                                                           | Added, Deprecated, or Removed                      |
|---------------------------------------------|---------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--defaults-extra-file=path</code>     | Read given file after global files are read                                           | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-file=path</code>           | Read default options from given file only                                             | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-group-suffix=string</code> | Also read groups with concat(group, suffix)                                           | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--help</code> ,                       | Display help text                                                                     | ADDED: NDB 7.6.4                                   |
| <code>-?</code>                             |                                                                                       |                                                    |
| <code>--login-path=path</code>              | Read given path from login file                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--ndb</code>                          | For compatibility with applications depending on old versions of perror; does nothing | ADDED: NDB 7.6.4                                   |
| <code>--no-defaults</code>                  | Do not read default options from any option file other than login file                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--print-defaults</code>               | Print program argument list and exit                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--silent</code> ,                     | Show error message only                                                               | ADDED: NDB 7.6.4                                   |
| <code>-s</code>                             |                                                                                       |                                                    |
| <code>--version</code> ,                    | Print program version information and exit                                            | ADDED: NDB 7.6.4                                   |
| <code>-V</code>                             |                                                                                       |                                                    |
| <code>--verbose</code> ,                    | Verbose output; disable with --silent                                                 | ADDED: NDB 7.6.4                                   |
| <code>-v</code>                             |                                                                                       |                                                    |

## Additional Options

- `--help`, `-?`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
| Introduced          | 5.7.19-ndb-7.6.4    |
| Type                | Boolean             |
| Default Value       | <code>TRUE</code>   |

Display program help text and exit.

- `--ndb`

|                     |                    |
|---------------------|--------------------|
| Command-Line Format | <code>--ndb</code> |
| Introduced          | 5.7.19-ndb-7.6.4   |
| Type                | Boolean            |
| Default Value       | <code>TRUE</code>  |

For compatibility with applications depending on old versions of perror that use that program's `--ndb` option. The option when used with `ndb_perror` does nothing, and is ignored by it.

- `--silent`, `-s`

|                     |                  |
|---------------------|------------------|
| Command-Line Format | --silent         |
| Introduced          | 5.7.19-ndb-7.6.4 |
| Type                | Boolean          |
| Default Value       | TRUE             |

Show error message only.

- --version, -V

|                     |                  |
|---------------------|------------------|
| Command-Line Format | --version        |
| Introduced          | 5.7.19-ndb-7.6.4 |
| Type                | Boolean          |
| Default Value       | TRUE             |

Print program version information and exit.

- --verbose, -v

|                     |                  |
|---------------------|------------------|
| Command-Line Format | --verbose        |
| Introduced          | 5.7.19-ndb-7.6.4 |
| Type                | Boolean          |
| Default Value       | TRUE             |

Verbose output; disable with --silent.

## 21.4.18 ndb\_print\_backup\_file — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

### Usage

```
ndb_print_backup_file file_name
```

*file\_name* is the name of a cluster backup file. This can be any of the files (.Data, .ctl, or .log file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory BACKUP-#, where # is the sequence number for the backup. For more information about cluster backup files and their contents, see [Section 21.5.8.1, “NDB Cluster Backup Concepts”](#).

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### Additional Options

None.

## 21.4.19 ndb\_print\_file — Print NDB Disk Data File Contents

`ndb_print_file` obtains information from an NDB Cluster Disk Data file.

### Usage

```
ndb_print_file [-v] [-q] file_name
```

*file\_name* is the name of an NDB Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_file` must be run on an NDB Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

## Additional Options

`ndb_print_file` supports the following options:

- `-v`: Make output verbose.
- `-q`: Suppress output (quiet mode).
- `--help`, `-h`, `-?`: Print help message.

For more information, see [Section 21.5.10, “NDB Cluster Disk Data Tables”](#).

## 21.4.20 ndb\_print\_frag\_file — Print NDB Fragment List File Contents

`ndb_print_frag_file` obtains information from a cluster fragment list file. It is intended for use in helping to diagnose issues with data node restarts.

## Usage

```
ndb_print_frag_file file_name
```

*file\_name* is the name of a cluster fragment list file, which matches the pattern `SX.FragList`, where `X` is a digit in the range 2-9 inclusive, and are found in the data node file system of the data node having the node ID `nodeid`, in directories named `ndb_nodeid_fs/DN/DBDIH/`, where `N` is 1 or 2. Each fragment file contains records of the fragments belonging to each NDB table. For more information about cluster fragment files, see [NDB Cluster Data Node File System Directory](#).

Like `ndb_print_backup_file`, `ndb_print_sys_file`, and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server), `ndb_print_frag_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

## Additional Options

None.

## Sample Output

```
shell> ndb_print_frag_file /usr/local/mysql/data/ndb_3_fs/D1/DBDIH/S2.FragList
Filename: /usr/local/mysql/data/ndb_3_fs/D1/DBDIH/S2.FragList with size 8192
noOfPages = 1 noOfWords = 182

```

## 21.4.21 `ndb_print_schema_file` — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

### Usage

```
ndb_print_schema_file file_name
```

*file\_name* is the name of a cluster schema file. For more information about cluster schema files, see [NDB Cluster Data Node File System Directory](#).

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_schema_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### Additional Options

None.

## 21.4.22 `ndb_print_sys_file` — Print NDB System File Contents

`ndb_print_sys_file` obtains diagnostic information from an NDB Cluster system file.

### Usage

```
ndb_print_sys_file file_name
```

*file\_name* is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb_#_fs/D#/DBDIH/P#.sysfile`. In each case, the `#` represents a number (not necessarily the same number). For more information, see [NDB Cluster Data Node File System Directory](#).

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### Additional Options

None.

## 21.4.23 `ndb_redo_log_reader` — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndb_redo_log_reader` is intended for use primarily by NDB Cluster developers and Support personnel in debugging and diagnosing problems.

This utility remains under development, and its syntax and behavior are subject to change in future NDB Cluster releases.

The C++ source files for `ndb_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

Options that can be used with `ndb_redo_log_reader` are shown in the following table. Additional descriptions follow the table.

**Table 21.37 Command-line options used with the program `ndb_redo_log_reader`**

| Format                        | Description                                          | Added, Deprecated, or Removed                      |
|-------------------------------|------------------------------------------------------|----------------------------------------------------|
| <code>-dump</code>            | Print dump info                                      | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-filedescriptors</code> | Print file descriptors only                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--help</code>           | Print usage information                              | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-lap</code>             | Provide lap info, with max GCI started and completed | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-mbyte #</code>         | Starting megabyte                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-mbyteheaders</code>    | Show only first page header of each megabyte in file | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-nocheck</code>         | Do not check records for errors                      | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-noprint</code>         | Do not print records                                 | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-page #</code>          | Start with this page                                 | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-pageheaders</code>     | Show page headers only                               | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-pageindex #</code>     | Start with this page index                           | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-twiddle</code>         | Bit-shifted dump                                     | (Supported in all NDB releases based on MySQL 5.7) |

## Usage

```
ndb_redo_log_reader file_name [options]
```

*file\_name* is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node's data directory (`DataDir`); the path under this directory to the redo log files matches the pattern `ndb_nodeid_fs/D#/DBLQH/S#.FragLog`. `nodeid` is the data node's node ID. The two instances of `#` each represent a number (not necessarily the same number); the number following `D` is in the range 8-39 inclusive; the range of the number following `S` varies according to the value of the `NoOfFragmentLogFile` configuration parameter, whose default value is 16; thus, the default range of the number in the file name is 0-15 inclusive. For more information, see [NDB Cluster Data Node File System Directory](#).

The name of the file to be read may be followed by one or more of the options listed here:

- **-dump**

|                     |                    |
|---------------------|--------------------|
| Command-Line Format | <code>-dump</code> |
| Type                | Boolean            |
| Default Value       | <code>FALSE</code> |

Print dump info.

- Command-Line Format      `-filedescriptors`
- |               |                    |
|---------------|--------------------|
| Type          | Boolean            |
| Default Value | <code>FALSE</code> |

`-filedescriptors`: Print file descriptors only.

- Command-Line Format      `--help`

`--help`: Print usage information.

- **-lap**

|                     |                    |
|---------------------|--------------------|
| Command-Line Format | <code>-lap</code>  |
| Type                | Boolean            |
| Default Value       | <code>FALSE</code> |

Provide lap info, with max GCI started and completed.

- Command-Line Format      `-mbyte #`
- |               |                 |
|---------------|-----------------|
| Type          | Numeric         |
| Default Value | <code>0</code>  |
| Minimum Value | <code>0</code>  |
| Maximum Value | <code>15</code> |

`-mbyte #`: Starting megabyte.

# is an integer in the range 0 to 15, inclusive.

- Command-Line Format      `-mbyteheaders`
- |               |                    |
|---------------|--------------------|
| Type          | Boolean            |
| Default Value | <code>FALSE</code> |

`-mbyteheaders`: Show only the first page header of every megabyte in the file.

- Command-Line Format      `-noprint`
- |               |                    |
|---------------|--------------------|
| Type          | Boolean            |
| Default Value | <code>FALSE</code> |

`-noprint`: Do not print the contents of the log file.

- Command-Line Format      `-nocheck`
- |               |                    |
|---------------|--------------------|
| Type          | Boolean            |
| Default Value | <code>FALSE</code> |

`-nocheck`: Do not check the log file for errors.

|                       |                      |
|-----------------------|----------------------|
| • Command-Line Format | <code>-page #</code> |
| Type                  | Integer              |
| Default Value         | 0                    |
| Minimum Value         | 0                    |
| Maximum Value         | 31                   |

`-page #`: Start at this page.

# is an integer in the range 0 to 31, inclusive.

|                       |                           |
|-----------------------|---------------------------|
| • Command-Line Format | <code>-pageheaders</code> |
| Type                  | Boolean                   |
| Default Value         | FALSE                     |

`-pageheaders`: Show page headers only.

|                       |                           |
|-----------------------|---------------------------|
| • Command-Line Format | <code>-pageindex #</code> |
| Type                  | Integer                   |
| Default Value         | 12                        |
| Minimum Value         | 12                        |
| Maximum Value         | 8191                      |

`-pageindex #`: Start at this page index.

# is an integer between 12 and 8191, inclusive.

- `-twiddle`

|                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>-twiddle</code> |
| Type                | Boolean               |
| Default Value       | FALSE                 |

Bit-shifted dump.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_redo_log_reader` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

## 21.4.24 ndb\_restore — Restore an NDB Cluster Backup

The NDB Cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

### Note

Beginning with NDB 7.5.15 and 7.6.11, this program no longer prints `NDBT_ProgramExit: ...` when it finishes its run. Applications depending on this behavior should be modified accordingly when upgrading from earlier releases.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see [Section 21.5.8.2, “Using The NDB Cluster](#)

[Management Client to Create a Backup](#)). This is equal to the number of data nodes in the cluster at the time that the backup was created.

**Note**

Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See [Section 21.5.6, “NDB Cluster Single User Mode”](#), for more information.

Options that can be used with `ndb_restore` are shown in the following table. Additional descriptions follow the table.

**Table 21.38 Command-line options used with the program `ndb_restore`**

| Format                                                              | Description                                                                          | Added, Deprecated, or Removed                      |
|---------------------------------------------------------------------|--------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--allow-pk-changes[=0 1]</code>                               | Allow changes to set of columns making up table's primary key                        | ADDED: NDB 7.6.14                                  |
| <code>--append</code>                                               | Append data to tab-delimited file                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--backup-path=dir_name</code>                                 | Path to backup files directory                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--backupid=#,</code><br><code>-b</code>                       | Restore from backup having this ID                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--character-sets-dir=path</code>                              | Directory containing character sets                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect,</code>                                             | Alias for --connectstring                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                                     |                                                                                      |                                                    |
| <code>--connect-retries=#</code>                                    | Number of times to retry connection before giving up                                 | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retry-delay=#</code>                                | Number of seconds to wait between attempts to contact management server              | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-string=connection-string,</code><br><code>-c</code> | Same as --ndb-connectstring                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--core-file</code>                                            | Write core file on error; used in debugging                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-extra-file=path</code>                             | Read given file after global files are read                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-file=path</code>                                   | Read default options from given file only                                            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-group-suffix=string</code>                         | Also read groups with concat(group, suffix)                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--disable-indexes</code>                                      | Causes indexes from backup to be ignored; may decrease time needed to restore data   | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--dont-ignore-systab-0,</code><br><code>-f</code>             | Do not ignore system table during restore; experimental only; not for production use | (Supported in all NDB releases based on MySQL 5.7) |

| Format                                         | Description                                                                                                                                            | Added, Deprecated, or Removed                      |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --exclude-databases=db-list                    | List of one or more databases to exclude (includes those not named)                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| --exclude-intermediate-sql-tables[=TRUE FALSE] | If TRUE (default), do not restore any intermediate tables (having names prefixed with '#sql-') that were left over from copying ALTER TABLE operations | (Supported in all NDB releases based on MySQL 5.7) |
| --exclude-missing-columns                      | Causes columns from backup version of table that are missing from version of table in database to be ignored                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --exclude-missing-tables                       | Causes tables from backup that are missing from database to be ignored                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| --exclude-tables=table-list                    | List of one or more tables to exclude (includes those in same database that are not named); each table reference must include database name            | (Supported in all NDB releases based on MySQL 5.7) |
| --fields-enclosed-by=char                      | Fields are enclosed by this character                                                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| --fields-optionally-enclosed-by                | Fields are optionally enclosed by this character                                                                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| --fields-terminated-by=char                    | Fields are terminated by this character                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| --help,                                        | Display help text and exit                                                                                                                             | (Supported in all NDB releases based on MySQL 5.7) |
| -?                                             |                                                                                                                                                        |                                                    |
| --hex                                          | Print binary types in hexadecimal format                                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| --ignore-extended-pk-updates[=0 1]             | Ignore log entries containing updates to columns now included in extended primary key                                                                  | ADDED: NDB 7.6.14                                  |
| --include-databases=db-list                    | List of one or more databases to restore (excludes those not named)                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| --include-tables=table-list                    | List of one or more tables to restore (excludes those in same database that are not named); each table reference must include database name            | (Supported in all NDB releases based on MySQL 5.7) |
| --lines-terminated-by=char                     | Lines are terminated by this character                                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| --login-path=path                              | Read given path from login file                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| --lossy-conversions,                           | Allow lossy conversions of column values (type demotions or changes in sign) when restoring data from backup                                           | (Supported in all NDB releases based on MySQL 5.7) |
| -L                                             |                                                                                                                                                        |                                                    |

| <b>Format</b>                          | <b>Description</b>                                                                                                                                       | <b>Added, Deprecated, or Removed</b>               |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --no-binlog                            | If mysqld is connected and using binary logging, do not log restored data                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| --no-defaults                          | Do not read default options from any option file other than login file                                                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| --no-restore-disk-objects,             | Do not restore objects relating to Disk Data                                                                                                             | (Supported in all NDB releases based on MySQL 5.7) |
| -d                                     |                                                                                                                                                          |                                                    |
| --no-upgrade,                          | Do not upgrade array type for varsize attributes which do not already resize VAR data, and do not change column attributes                               | (Supported in all NDB releases based on MySQL 5.7) |
| -u                                     |                                                                                                                                                          |                                                    |
| --ndb-connectstring=connection-string, | Set connect string for connecting to ndb_mgmd.<br>Syntax: "[nodeid=id;]<br>[host=]hostname[:port]".<br>Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.7) |
| -c                                     |                                                                                                                                                          |                                                    |
| --ndb-mgmd-host=connection-string,     | Same as --ndb-connectstring                                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| -c                                     |                                                                                                                                                          |                                                    |
| --ndb-nodegroup-map=map,               | Nodegroup map for NDBCLOUD storage engine;<br>syntax: list of (source_nodegroup, destination_nodegroup)                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| -z                                     |                                                                                                                                                          |                                                    |
| --ndb-nodeid=#                         | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-optimized-node-selection         | Enable optimizations for selection of nodes for transactions.<br>Enabled by default; use --skip-ndb-optimized-node-selection to disable                  | (Supported in all NDB releases based on MySQL 5.7) |
| --nodeid=#,                            | ID of node where backup was taken                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| -n                                     |                                                                                                                                                          |                                                    |
| --num-slices=#                         | Number of slices to apply when restoring by slice                                                                                                        | ADDED: NDB 7.6.13                                  |
| --parallelism=#,                       | Number of parallel transactions to use while restoring data                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| -p                                     |                                                                                                                                                          |                                                    |
| --preserve-trailing-spaces,            | Allow preservation of trailing spaces (including padding) when promoting fixed-width string types to variable-width types                                | (Supported in all NDB releases based on MySQL 5.7) |
| -P                                     |                                                                                                                                                          |                                                    |
| --print                                | Print metadata, data, and log to stdout (equivalent to --print-meta --print-data --print-log)                                                            | (Supported in all NDB releases based on MySQL 5.7) |

| Format                                          | Description                                                                                                                                          | Added, Deprecated, or Removed                      |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --print-data                                    | Print data to stdout                                                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| --print-defaults                                | Print program argument list and exit                                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| --print-log                                     | Print log to stdout                                                                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| --print-meta                                    | Print metadata to stdout                                                                                                                             | (Supported in all NDB releases based on MySQL 5.7) |
| --print-sql-log                                 | Write SQL log to stdout; default is FALSE                                                                                                            | ADDED: NDB 7.5.4                                   |
| --progress-frequency=#                          | Print status of restore each given number of seconds                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| --promote-attributes,<br>-A                     | Allow attributes to be promoted when restoring data from backup                                                                                      | (Supported in all NDB releases based on MySQL 5.7) |
| --rebuild-indexes                               | Causes multithreaded rebuilding of ordered indexes found in backup; number of threads used is determined by setting BuildIndexThreads                | (Supported in all NDB releases based on MySQL 5.7) |
| --remap-column=[db].<br>[tbl].[col]:[fn]:[args] | Apply offset to value of specified column using indicated function and arguments                                                                     | ADDED: NDB 7.6.14                                  |
| --restore-data,<br>-r                           | Restore table data and logs into NDB Cluster using NDB API                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --restore-epoch,<br>-e                          | Restore epoch info into status table; useful on replica cluster for starting replication; updates or inserts row in mysql.ndb_apply_status with ID 0 | (Supported in all NDB releases based on MySQL 5.7) |
| --restore-meta,<br>-m                           | Restore metadata to NDB Cluster using NDB API                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| --restore-privilege-tables                      | Restore MySQL privilege tables that were previously moved to NDB                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --rewrite-database=olddb,newdb                  | Restore to differently named database                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| --skip-broken-objects                           | Ignore missing blob tables in backup file                                                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| --skip-table-check,<br>-s                       | Skip table structure check during restore                                                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| --skip-unknown-objects                          | Causes schema objects not recognized by ndb_restore to be ignored when restoring backup made from newer NDB version to older version                 | (Supported in all NDB releases based on MySQL 5.7) |
| --slice-id=#                                    | Slice ID, when restoring by slices                                                                                                                   | ADDED: NDB 7.6.13                                  |

| Format                         | Description                                                       | Added, Deprecated, or Removed                      |
|--------------------------------|-------------------------------------------------------------------|----------------------------------------------------|
| --tab=dir_name,<br>-T dir_name | Creates a tab-separated .txt file for each table in path provided | (Supported in all NDB releases based on MySQL 5.7) |
| --usage,<br>-?                 | Display help text and exit; same as --help                        | (Supported in all NDB releases based on MySQL 5.7) |
| --verbose=#                    | Level of verbosity in output                                      | (Supported in all NDB releases based on MySQL 5.7) |
| --version,<br>-V               | Display version information and exit                              | (Supported in all NDB releases based on MySQL 5.7) |

- `--allow-pk-changes`

|                     |                                       |
|---------------------|---------------------------------------|
| Command-Line Format | <code>--allow-pk-changes[=0 1]</code> |
| Introduced          | 5.7.29-ndb-7.6.14                     |
| Type                | Integer                               |
| Default Value       | 0                                     |
| Minimum Value       | 0                                     |
| Maximum Value       | 1                                     |

When this option is set to 1, `ndb_restore` allows the primary keys in a table definition to differ from that of the same table in the backup. This may be desirable when backing up and restoring between different schema versions with primary key changes on one or more tables, and it appears that performing the restore operation using `ndb_restore` is simpler or more efficient than issuing many `ALTER TABLE` statements after restoring table schemas and data.

The following changes in primary key definitions are supported by `--allow-pk-changes`:

- **Extending the primary key:** A non-nullable column that exists in the table schema in the backup becomes part of the table's primary key in the database.

#### Important

When extending a table's primary key, any columns which become part of primary key must not be updated while the backup is being taken; any such updates discovered by `ndb_restore` cause the restore operation to fail, even when no change in value takes place. In some cases, it may be possible to override this behavior using the `--ignore-extended-pk-updates` option; see the description of this option for more information.

- **Contracting the primary key (1):** A column that is already part of the table's primary key in the backup schema is no longer part of the primary key, but remains in the table.
- **Contracting the primary key (2):** A column that is already part of the table's primary key in the backup schema is removed from the table entirely.

These differences can be combined with other schema differences supported by `ndb_restore`, including changes to blob and text columns requiring the use of staging tables.

Basic steps in a typical scenario using primary key schema changes are listed here:

1. Restore table schemas using `ndb_restore --restore-meta`
2. Alter schema to that desired, or create it

3. Back up the desired schema
4. Run `ndb_restore --disable-indexes` using the backup from the previous step, to drop indexes and constraints
5. Run `ndb_restore --allow-pk-changes` (possibly along with `--ignore-extended-pk-updates`, `--disable-indexes`, and possibly other options as needed) to restore all data
6. Run `ndb_restore --rebuild-indexes` using the backup made with the desired schema, to rebuild indexes and constraints

When extending the primary key, it may be necessary for `ndb_restore` to use a temporary secondary unique index during the restore operation to map from the old primary key to the new one. Such an index is created only when necessary to apply events from the backup log to a table which has an extended primary key. This index is named `NDB$RESTORE_PK_MAPPING`, and is created on each table requiring it; it can be shared, if necessary, by multiple instances of `ndb_restore` instances running in parallel. (Running `ndb_restore --rebuild-indexes` at the end of the restore process causes this index to be dropped.)

- `--append`

|                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>--append</code> |
|---------------------|-----------------------|

When used with the `--tab` and `--print-data` options, this causes the data to be appended to any existing files having the same names.

- `--backup-path=dir_name`

|                     |                                     |
|---------------------|-------------------------------------|
| Command-Line Format | <code>--backup-path=dir_name</code> |
| Type                | Directory name                      |
| Default Value       | <code>./</code>                     |

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup-path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's `DataDir` is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located, and may be optionally prefixed with `backup-path=`.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two storage nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice—once for each storage node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See [Section 21.2.7, “Upgrading and Downgrading NDB Cluster”](#), for more information.

### Important

It is not possible to restore a backup made from a newer version of NDB Cluster using an older version of `ndb_restore`. You can restore a backup

made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer NDB Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running NDB Cluster 7.5.23 to a cluster running NDB Cluster 7.4.33, you must use the `ndb_restore` that comes with the NDB Cluster 7.5.23 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

- `--backupid=#, -b`

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>--backupid=#</code> |
| Type                | Numeric                   |
| Default Value       | <code>none</code>         |

This option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon completion of a backup. (See [Section 21.5.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#).)

#### Important

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups can at best result in restoring the cluster to an inconsistent state, and may fail altogether.

In NDB 7.5.13 and later, and in NDB 7.6.9 and later, this option is required.

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- `--connect, -c`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--connect</code>      |
| Type                | String                      |
| Default Value       | <code>localhost:1186</code> |

Alias for `--ndb-connectstring`.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | <code>12</code>                  |
| Minimum Value       | <code>0</code>                   |
| Maximum Value       | <code>12</code>                  |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 5                                    |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | [none]                                          |

Same as `--ndb-connectstring`.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | [none]                                  |

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | [none]                            |

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | [none]                                      |

Also read groups with concat(group, suffix).

- `--disable-indexes`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--disable-indexes</code> |
|---------------------|--------------------------------|

Disable restoration of indexes during restoration of the data from a native `NDB` backup. Afterwards, you can restore indexes for all tables at once with multithreaded building of indexes using `--rebuild-indexes`, which should be faster than rebuilding indexes concurrently for very large tables.

- `--dont-ignore-systab-0, -f`

|                     |                                     |
|---------------------|-------------------------------------|
| Command-Line Format | <code>--dont-ignore-systab-0</code> |
|---------------------|-------------------------------------|

Normally, when restoring table data and metadata, `ndb_restore` ignores the copy of the NDB system table that is present in the backup. `--dont-ignore-systab-0` causes the system table to be restored. *This option is intended for experimental and development use only, and is not recommended in a production environment.*

- `--exclude-databases=db-list`

|                     |                                          |
|---------------------|------------------------------------------|
| Command-Line Format | <code>--exclude-databases=db-list</code> |
| Type                | String                                   |
| Default Value       |                                          |

Comma-delimited list of one or more databases which should not be restored.

This option is often used in combination with `--exclude-tables`; see that option's description for further information and examples.

- `--exclude-intermediate-sql-tables[=TRUE|FALSE]`

|                     |                                                             |
|---------------------|-------------------------------------------------------------|
| Command-Line Format | <code>--exclude-intermediate-sql-tables[=TRUE FALSE]</code> |
| Type                | Boolean                                                     |
| Default Value       | TRUE                                                        |

When performing copying `ALTER TABLE` operations, `mysqld` creates intermediate tables (whose names are prefixed with `#sql-`). When `TRUE`, the `--exclude-intermediate-sql-tables` option keeps `ndb_restore` from restoring such tables that may have been left over from these operations. This option is `TRUE` by default.

- `--exclude-missing-columns`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--exclude-missing-columns</code> |
|---------------------|----------------------------------------|

It is possible to restore only selected table columns using this option, which causes `ndb_restore` to ignore any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the `--include-*` or `--exclude-*` options described elsewhere in this section to do so, then restore data to the remaining tables using a complementary set of these options.

- `--exclude-missing-tables`

|                     |                                       |
|---------------------|---------------------------------------|
| Command-Line Format | <code>--exclude-missing-tables</code> |
|---------------------|---------------------------------------|

It is possible to restore only selected tables using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

- `--exclude-tables=table-list`

|                     |                                          |
|---------------------|------------------------------------------|
| Command-Line Format | <code>--exclude-tables=table-list</code> |
| Type                | String                                   |
| Default Value       |                                          |

List of one or more tables to exclude; each table reference must include the database name. Often used together with `--exclude-databases`.

When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

This table shows several invocations of `ndb_restore` using `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from an NDB Cluster backup:

**Table 21.39 Several invocations of `ndb_restore` using `--exclude-*` options, and the effects these options have on restoring from an NDB Cluster backup.**

| Option                                                                                                         | Result                                                                                                                                                                                                                                                                             |
|----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--exclude-databases=db1</code>                                                                           | All tables in all databases except <code>db1</code> are restored; no tables in <code>db1</code> are restored                                                                                                                                                                       |
| <code>--exclude-databases=db1,db2</code> (or <code>--exclude-databases=db1 --exclude-databases=db2</code> )    | All tables in all databases except <code>db1</code> and <code>db2</code> are restored; no tables in <code>db1</code> or <code>db2</code> are restored                                                                                                                              |
| <code>--exclude-tables=db1.t1</code>                                                                           | All tables except <code>t1</code> in database <code>db1</code> are restored; all other tables in <code>db1</code> are restored; all tables in all other databases are restored                                                                                                     |
| <code>--exclude-tables=db1.t2,db2.t1</code> (or <code>--exclude-tables=db1.t2 --exclude-tables=db2.t1</code> ) | All tables in database <code>db1</code> except for <code>t2</code> and all tables in database <code>db2</code> except for table <code>t1</code> are restored; no other tables in <code>db1</code> or <code>db2</code> are restored; all tables in all other databases are restored |

You can use these two options together. For example, the following causes all tables in all databases *except for* databases `db1` and `db2`, and tables `t1` and `t2` in database `db3`, to be restored:

```
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

You can use `--include-*` and `--exclude-*` options together, subject to the following rules:

- The actions of all `--include-*` and `--exclude-*` options are cumulative.
- All `--include-*` and `--exclude-*` options are evaluated in the order passed to `ndb_restore`, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table “wins”.

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` *except* `db1.t1`, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```
--exclude-tables=db1.t1 --include-databases=db1
```

- `--fields-enclosed-by=char`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--fields-enclosed-by=char</code> |
|---------------------|----------------------------------------|

|               |        |
|---------------|--------|
| Type          | String |
| Default Value |        |

Each column value is enclosed by the string passed to this option (regardless of data type; see the description of [--fields-optionally-enclosed-by](#)).

- [--fields-optionally-enclosed-by](#)

|                     |                                              |
|---------------------|----------------------------------------------|
| Command-Line Format | <code>--fields-optionally-enclosed-by</code> |
| Type                | String                                       |
| Default Value       |                                              |

The string passed to this option is used to enclose column values containing character data (such as CHAR, VARCHAR, BINARY, TEXT, or ENUM).

- [--fields-terminated-by=char](#)

|                     |                                          |
|---------------------|------------------------------------------|
| Command-Line Format | <code>--fields-terminated-by=char</code> |
| Type                | String                                   |
| Default Value       | \t (tab)                                 |

The string passed to this option is used to separate column values. The default value is a tab character (\t).

- [--help](#)

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- [--hex](#)

|                     |                    |
|---------------------|--------------------|
| Command-Line Format | <code>--hex</code> |
|---------------------|--------------------|

If this option is used, all binary values are output in hexadecimal format.

- [--ignore-extended-pk-updates](#)

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--ignore-extended-pk-updates[=0 1]</code> |
| Introduced          | 5.7.29-ndb-7.6.14                               |
| Type                | Integer                                         |
| Default Value       | 0                                               |
| Minimum Value       | 0                                               |
| Maximum Value       | 1                                               |

When using the [--allow-pk-changes](#) option, columns which become part of a table's primary key must not be updated while the backup is being taken; such columns should keep the same values from the time values are inserted into them until the rows containing the values are deleted. If `ndb_restore` encounters updates to these columns when restoring a backup, the restore fails. Because some applications may set values for all columns when updating a row, even when some column values are not changed, the backup may include log events appearing to update columns

which are not in fact modified. In such cases you can set `--ignore-extended-pk-updates` to 1, forcing `ndb_restore` to ignore such updates.

### Important

When causing these updates to be ignored, the user is responsible for ensuring that there are no updates to the values of any columns that become part of the primary key.

For more information, see the description of `--allow-pk-changes`.

- `--include-databases=db-list`

|                     |                                          |
|---------------------|------------------------------------------|
| Command-Line Format | <code>--include-databases=db-list</code> |
| Type                | String                                   |
| Default Value       |                                          |

Comma-delimited list of one or more databases to restore. Often used together with `--include-tables`; see the description of that option for further information and examples.

- `--include-tables=table-list`

|                     |                                          |
|---------------------|------------------------------------------|
| Command-Line Format | <code>--include-tables=table-list</code> |
| Type                | String                                   |
| Default Value       |                                          |

Comma-delimited list of tables to restore; each table reference must include the database name.

When `--include-databases` or `--include-tables` is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by `ndb_restore`, and are not restored.

The following table shows several invocations of `ndb_restore` using `--include-*` options (other options possibly required have been omitted for clarity), and the effects these have on restoring from an NDB Cluster backup:

**Table 21.40 Several invocations of `ndb_restore` using `--include-*` options, and their effects on restoring from an NDB Cluster backup.**

| Option                                                                                                      | Result                                                                                                                                         |
|-------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--include-databases=db1</code>                                                                        | Only tables in database <code>db1</code> are restored; all tables in all other databases are ignored                                           |
| <code>--include-databases=db1,db2</code> (or <code>--include-databases=db1 --include-databases=db2</code> ) | Only tables in databases <code>db1</code> and <code>db2</code> are restored; all tables in all other databases are ignored                     |
| <code>--include-tables=db1.t1</code>                                                                        | Only table <code>t1</code> in database <code>db1</code> is restored; no other tables in <code>db1</code> or in any other database are restored |

| Option                                                                                 | Result                                                                                                                                                                                                                           |
|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --include-tables=db1.t2,db2.t1 (or<br>--include-tables=db1.t2 --include-tables=db2.t1) | Only the table <code>t2</code> in database <code>db1</code> and the table <code>t1</code> in database <code>db2</code> are restored; no other tables in <code>db1</code> , <code>db2</code> , or any other database are restored |

You can also use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```
shell> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

It is also possible to restore only selected databases, or selected tables from a single database, without any `--include-*` (or `--exclude-*`) options, using the syntax shown here:

```
ndb_restore other_options db_name,[db_name[,...] | tbl_name[,tbl_name][,...]]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database
- `--lines-terminated-by=char`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--lines-terminated-by=char</code> |
| Type                | String                                  |
| Default Value       | <code>\n (linebreak)</code>             |

Specifies the string used to end each line of output. The default is a linefeed character (`\n`).

- `--login-path`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type                | String                         |
| Default Value       | <code>[none]</code>            |

Read given path from login file.

- `--lossy-conversions, -L`

|                     |                                            |
|---------------------|--------------------------------------------|
| Command-Line Format | <code>--lossy-conversions</code>           |
| Type                | Boolean                                    |
| Default Value       | <code>FALSE</code> (If option is not used) |

This option is intended to complement the `--promote-attributes` option. Using `--lossy-conversions` allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see [Replication of Columns Having Different Data Types](#), for information about specific type conversions currently supported by attribute demotion.

Beginning with NDB 7.5.23 and NDB 7.6.19, this option also makes it possible to restore a `NULL` column as `NOT NULL`. The column must not contain any `NULL` entries; otherwise `ndb_restore` stops with an error.

`ndb_restore` reports any truncation of data that it performs during lossy conversions once per attribute and column.

- `--ndb-connectstring`

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |
| Default Value       | [none]                                             |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | [none]                                         |

Same as `--ndb-connectstring`.

- `--ndb-nodegroup-map=map`, `-z`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--ndb-nodegroup-map=map</code> |
|---------------------|--------------------------------------|

This option can be used to restore a backup taken from one node group to a different node group. Its argument is a list of the form `source_node_group`, `target_node_group`.

- `--ndb-nodeid`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | [none]                      |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-binlog`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--no-binlog</code> |
|---------------------|--------------------------|

This option prevents any connected SQL nodes from writing data restored by `ndb_restore` to their binary logs.

- `--no-defaults`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--no-restore-disk-objects`, `-d`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--no-restore-disk-objects</code> |
|---------------------|----------------------------------------|

|               |                    |
|---------------|--------------------|
| Default Value | <code>FALSE</code> |
|---------------|--------------------|

This option stops `ndb_restore` from restoring any NDB Cluster Disk Data objects, such as tablespaces and log file groups; see [Section 21.5.10, “NDB Cluster Disk Data Tables”](#), for more information about these.

- `--no-upgrade`, `-u`

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>--no-upgrade</code> |
|---------------------|---------------------------|

When using `ndb_restore` to restore a backup, `VARCHAR` columns created using the old fixed format are resized and recreated using the variable-width format now employed. This behavior can be overridden by specifying `--no-upgrade`.

- `--nodeid=#`, `-n`

|                     |                         |
|---------------------|-------------------------|
| Command-Line Format | <code>--nodeid=#</code> |
| Type                | Numeric                 |
| Default Value       | <code>none</code>       |

Specify the node ID of the data node on which the backup was taken.

When restoring to a cluster with different number of data nodes from that where the backup was taken, this information helps identify the correct set or sets of files to be restored to a given node. (In such cases, multiple files usually need to be restored to a single data node.) See [Section 21.4.24.2, “Restoring to a different number of data nodes”](#), for additional information and examples.

In NDB 7.5.13 and later, and in NDB 7.6.9 and later, this option is required.

- `--num-slices=#`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--num-slices=#</code> |
| Introduced          | 5.7.29-ndb-7.6.13           |
| Type                | Integer                     |
| Default Value       | <code>1</code>              |
| Minimum Value       | <code>1</code>              |
| Maximum Value       | <code>1024</code>           |

When restoring a backup by slices, this option sets the number of slices into which to divide the backup. This allows multiple instances of `ndb_restore` to restore disjoint subsets in parallel, potentially reducing the amount of time required to perform the restore operation.

A *slice* is a subset of the data in a given backup; that is, it is a set of fragments having the same slice ID, specified using the `--slice-id` option. The two options must always be used together, and the value set by `--slice-id` must always be less than the number of slices.

`ndb_restore` encounters fragments and assigns each one a fragment counter. When restoring by slices, a slice ID is assigned to each fragment; this slice ID is in the range 0 to 1 less than the

number of slices. For a table that is not a `BLOB` table, the slice to which a given fragment belongs is determined using the formula shown here:

|                                                                   |
|-------------------------------------------------------------------|
| <code>[slice_ID] = [fragment_counter] % [number_of_slices]</code> |
|-------------------------------------------------------------------|

For a `BLOB` table, a fragment counter is not used; the fragment number is used instead, along with the ID of the main table for the `BLOB` table (recall that `NDB` stores `BLOB` values in a separate table internally). In this case, the slice ID for a given fragment is calculated as shown here:

|                                                                                  |
|----------------------------------------------------------------------------------|
| <code>[slice_ID] = ([main_table_ID] + [fragment_ID]) % [number_of_slices]</code> |
|----------------------------------------------------------------------------------|

Thus, restoring by `N` slices means running `N` instances of `ndb_restore`, all with `--num-slices=N` (along with any other necessary options) and one each with `--slice-id=1`, `--slice-id=2`, `--slice-id=3`, and so on through `slice-id=N-1`.

- `--parallelism=#`, `-p`

|                     |                              |
|---------------------|------------------------------|
| Command-Line Format | <code>--parallelism=#</code> |
| Type                | Numeric                      |
| Default Value       | <code>128</code>             |
| Minimum Value       | <code>1</code>               |
| Maximum Value       | <code>1024</code>            |

`ndb_restore` uses single-row transactions to apply many rows concurrently. This parameter determines the number of parallel transactions (concurrent rows) that an instance of `ndb_restore` tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

The work of performing the inserts is parallelized across the threads in the data nodes involved. This mechanism is employed for restoring bulk data from the `.Data` file—that is, the fuzzy snapshot of the data; it is not used for building or rebuilding indexes. The change log is applied serially; index drops and builds are DDL operations and handled separately. There is no thread-level parallelism on the client side of the restore.

- `--preserve-trailing-spaces`, `-P`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--preserve-trailing-spaces</code> |
|---------------------|-----------------------------------------|

Cause trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a `CHAR` column value to `VARCHAR`, or a `BINARY` column value to `VARBINARY`. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

#### Note

Although you can promote `CHAR` columns to `VARCHAR` and `BINARY` columns to `VARBINARY`, you cannot promote `VARCHAR` columns to `CHAR` or `VARBINARY` columns to `BINARY`.

- `--print`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--print</code> |
| Type                | Boolean              |

|               |              |
|---------------|--------------|
| Default Value | <b>FALSE</b> |
|---------------|--------------|

Causes `ndb_restore` to print all data, metadata, and logs to `stdout`. Equivalent to using the `--print-data`, `--print-meta`, and `--print-log` options together.

**Note**

Use of `--print` or any of the `--print_*` options is in effect performing a dry run. Including one or more of these options causes any output to be redirected to `stdout`; in such cases, `ndb_restore` makes no attempt to restore data or metadata to an NDB Cluster.

- `--print-data`

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>--print-data</code> |
| Type                | Boolean                   |
| Default Value       | <b>FALSE</b>              |

Cause `ndb_restore` to direct its output to `stdout`. Often used together with one or more of `--tab`, `--fields-enclosed-by`, `--fields-optionally-enclosed-by`, `--fields-terminated-by`, `--hex`, and `--append`.

`TEXT` and `BLOB` column values are always truncated. Such values are truncated to the first 256 bytes in the output. This cannot currently be overridden when using `--print-data`.

- `--print-defaults`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--print-log`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--print-log</code> |
| Type                | Boolean                  |
| Default Value       | <b>FALSE</b>             |

Cause `ndb_restore` to output its log to `stdout`.

- `--print-meta`

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>--print-meta</code> |
| Type                | Boolean                   |
| Default Value       | <b>FALSE</b>              |

Print all metadata to `stdout`.

- `print-sql-log`

|                     |                              |
|---------------------|------------------------------|
| Command-Line Format | <code>--print-sql-log</code> |
| Introduced          | 5.7.16-ndb-7.5.4             |
| Type                | Boolean                      |
| Default Value       | <b>FALSE</b>                 |

Log SQL statements to `stdout`. Use the option to enable; normally this behavior is disabled. The option checks before attempting to log whether all the tables being restored have explicitly defined

primary keys; queries on a table having only the hidden primary key implemented by NDB cannot be converted to valid SQL.

This option does not work with tables having `BLOB` columns.

The `--print-sql-log` option was added in NDB 7.5.4. (Bug #13511949)

- `--progress-frequency=N`

|                     |                                     |
|---------------------|-------------------------------------|
| Command-Line Format | <code>--progress-frequency=#</code> |
| Type                | Numeric                             |
| Default Value       | 0                                   |
| Minimum Value       | 0                                   |
| Maximum Value       | 65535                               |

Print a status report each `N` seconds while the backup is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

- `--promote-attributes, -A`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--promote-attributes</code> |
|---------------------|-----------------------------------|

`ndb_restore` supports limited *attribute promotion* in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a `CHAR(20)` column can be restored to a column declared as `VARCHAR(20)`, `VARCHAR(30)`, or `CHAR(30)`; data from a `MEDIUMINT` column can be restored to a column of type `INT` or `BIGINT`. See [Replication of Columns Having Different Data Types](#), for a table of type conversions currently supported by attribute promotion.

Beginning with NDB 7.5.23 and NDB 7.6.19, this option also makes it possible to restore a `NOT NULL` column as `NULL`.

Attribute promotion by `ndb_restore` must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. `ndb_restore` cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using `ALTER TABLE` after restoring the table metadata but before restoring the data.
2. Invoke `ndb_restore` with the `--promote-attributes` option (short form `-A`) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

When converting between character data types and `TEXT` or `BLOB`, only conversions between character types (`CHAR` and `VARCHAR`) and binary types (`BINARY` and `VARBINARY`) can be performed at the same time. For example, you cannot promote an `INT` column to `BIGINT` while promoting a `VARCHAR` column to `TEXT` in the same invocation of `ndb_restore`.

Converting between `TEXT` columns using different character sets is not supported, and is expressly disallowed.

When performing conversions of character or binary types to `TEXT` or `BLOB` with `ndb_restore`, you may notice that it creates and uses one or more staging tables named `table_name$STnode_id`. These tables are not needed afterwards, and are normally deleted by `ndb_restore` following a successful restoration.

- `--rebuild-indexes`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--rebuild-indexes</code> |
|---------------------|--------------------------------|

Enable multithreaded rebuilding of the ordered indexes while restoring a native `NDB` backup. The number of threads used for building ordered indexes by `ndb_restore` with this option is controlled by the `BuildIndexThreads` data node configuration parameter and the number of LDMs.

It is necessary to use this option only for the first run of `ndb_restore`; this causes all ordered indexes to be rebuilt without using `--rebuild-indexes` again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

Building of ordered indices is parallelized with the number of LDMs by default. Offline index builds performed during node and system restarts can be made faster using the `BuildIndexThreads` data node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by `ndb_restore`, which is performed online.

Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwidth can lead to redo buffer overload or log overload errors. In such cases you can run `ndb_restore --rebuild-indexes` again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of `ndb_restore --rebuild-indexes` indefinitely; you may be able to stop such errors by reducing the value of `--parallelism`. If the problem is insufficient space, you can increase the size of the redo log (`FragmentLogFileSize` node configuration parameter), or you can increase the speed at which LCPs are performed (`MaxDiskWriteSpeed` and related parameters), in order to free space more quickly.

- `--remap-column=db.tbl.col:fn:args`

|                     |                                                          |
|---------------------|----------------------------------------------------------|
| Command-Line Format | <code>--remap-column=[db].[tbl].[col]:[fn]:[args]</code> |
| Introduced          | 5.7.29-ndb-7.6.14                                        |
| Type                | String                                                   |
| Default Value       | <code>[none]</code>                                      |

When used together with `--restore-data`, this option applies a function to the value of the indicated column. Values in the argument string are listed here:

- `db`: Database name, following any renames performed by `--rewrite-database`.
- `tbl`: Table name.
- `col`: Name of the column to be updated. This column must be of type `INT` or `BIGINT`. The column can also be but is not required to be `UNSIGNED`.
- `fn`: Function name; currently, the only supported name is `offset`.
- `args`: Arguments supplied to the function. Currently, only a single argument, the size of the offset to be added by the `offset` function, is supported. Negative values are supported. The size of the argument cannot exceed that of the signed variant of the column's type; for example, if `col` is an `INT` column, then the allowed range of the argument passed to the `offset` function is `-2147483648` to `2147483647` (see [Section 11.1.2, “Integer Types \(Exact Value\) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”](#)).

If applying the offset value to the column would cause an overflow or underflow, the restore operation fails. This could happen, for example, if the column is a `BIGINT`, and the option

attempts to apply an offset value of 8 on a row in which the column value is 4294967291, since  
 $4294967291 + 8 = 4294967299 > 4294967295$ .

This option can be useful when you wish to merge data stored in multiple source instances of NDB Cluster (all using the same schema) into a single destination NDB Cluster, using NDB native backup (see [Section 21.5.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#)) and `ndb_restore` to merge the data, where primary and unique key values are overlapping between source clusters, and it is necessary as part of the process to remap these values to ranges that do not overlap. It may also be necessary to preserve other relationships between tables. To fulfill such requirements, it is possible to use the option multiple times in the same invocation of `ndb_restore` to remap columns of different tables, as shown here:

```
shell> ndb_restore --restore-data --remap-column=hr.employee.id:offset:1000 \
 --remap-column=hr.manager.id:offset:1000 --remap-column=hr.firstaiders.id:offset:1000
```

(Other options not shown here may also be used.)

`--remap-column` can also be used to update multiple columns of the same table. Combinations of multiple tables and columns are possible. Different offset values can also be used for different columns of the same table, like this:

```
shell> ndb_restore --restore-data --remap-column=hr.employee.salary:offset:10000 \
 --remap-column=hr.employee.hours:offset:-10
```

When source backups contain duplicate tables which should not be merged, you can handle this by using `--exclude-tables`, `--exclude-databases`, or by some other means in your application.

Information about the structure and other characteristics of tables to be merged can obtained using `SHOW CREATE TABLE`; the `ndb_desc` tool; and `MAX()`, `MIN()`, `LAST_INSERT_ID()`, and other MySQL functions.

Replication of changes from merged to unmerged tables, or from unmerged to merged tables, in separate instances of NDB Cluster is not supported.

- `--restore-data`, `-r`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--restore-data</code> |
| Type                | Boolean                     |
| Default Value       | <code>FALSE</code>          |

Output NDB table data and logs.

- `--restore-epoch`, `-e`

|                     |                              |
|---------------------|------------------------------|
| Command-Line Format | <code>--restore-epoch</code> |
|---------------------|------------------------------|

Add (or restore) epoch information to the cluster replication status table. This is useful for starting replication on an NDB replica cluster. When this option is used, the row in the `mysql.ndb_apply_status` having `0` in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See [Section 21.6.9, “NDB Cluster Backups With NDB Cluster Replication”](#).)

- `--restore-meta`, `-m`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--restore-meta</code> |
| Type                | Boolean                     |

|               |                    |
|---------------|--------------------|
| Default Value | <code>FALSE</code> |
|---------------|--------------------|

This option causes `ndb_restore` to print NDB table metadata.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the `--restore-meta (-m)` option. Restoring the metadata need be done only on a single data node; this is sufficient to restore it to the entire cluster.

In older versions of NDB Cluster, tables whose schemas were restored using this option used the same number of partitions as they did on the original cluster, even if it had a differing number of data nodes from the new cluster. In NDB 7.5.2 and later, when restoring metadata, this is no longer an issue; `ndb_restore` now uses the default number of partitions for the target cluster, unless the number of local data manager threads is also changed from what it was for data nodes in the original cluster.

#### Note

The cluster should have an empty database when starting to restore a backup. (In other words, you should start the data nodes with `--initial` prior to performing the restore.)

- `--restore-privilege-tables`

|                     |                                            |
|---------------------|--------------------------------------------|
| Command-Line Format | <code>--restore-privilege-tables</code>    |
| Type                | Boolean                                    |
| Default Value       | <code>FALSE</code> (If option is not used) |

`ndb_restore` does not by default restore distributed MySQL privilege tables. This option causes `ndb_restore` to restore the privilege tables.

This works only if the privilege tables were converted to NDB before the backup was taken. For more information, see [Section 21.5.12, “Distributed Privileges Using Shared Grant Tables”](#).

- `--rewrite-database=olddb,newdb`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--rewrite-database=olddb,newdb</code> |
| Type                | String                                      |
| Default Value       | <code>none</code>                           |

This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named `products`, you can restore the data it contains to a database named `inventory`, use this option as shown here (omitting any other options that might be required):

```
shell> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of `ndb_restore`. Thus it is possible to restore simultaneously from a database named `db1` to a database named `db2` and from a database named `db3` to one named `db4` using `--rewrite-database=db1,db2 --rewrite-database=db3,db4`. Other `ndb_restore` options may be used between multiple occurrences of `--rewrite-database`.

In the event of conflicts between multiple `--rewrite-database` options, the last `--rewrite-database` option used, reading from left to right, is the one that takes effect. For example, if `--rewrite-database=db1,db2 --rewrite-database=db1,db3` is used, only `--rewrite-database=db1,db3` is honored, and `--rewrite-database=db1,db2` is ignored. It is also possible to restore from multiple databases to a single database, so that `--rewrite-` 3349

`database=db1,db3 --rewrite-database=db2,db3` restores all tables and data from databases `db1` and `db2` into database `db3`.

### Important

When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

- `--skip-broken-objects`

|                     |                                    |
|---------------------|------------------------------------|
| Command-Line Format | <code>--skip-broken-objects</code> |
|---------------------|------------------------------------|

This option causes `ndb_restore` to ignore corrupt tables while reading a native `NDB` backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the `--skip-broken-objects` option works only in the case of missing blob parts tables.

- `--skip-table-check, -s`

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | <code>--skip-table-check</code> |
|---------------------|---------------------------------|

It is possible to restore data without restoring table metadata. By default when doing this, `ndb_restore` fails with an error if a mismatch is found between the table data and the table schema; this option overrides that behavior.

Some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
- Different `STORAGE` settings (`MEMORY`, `DISK`)
- Different default values
- Different distribution key settings
- `--skip-unknown-objects`

|                     |                                     |
|---------------------|-------------------------------------|
| Command-Line Format | <code>--skip-unknown-objects</code> |
|---------------------|-------------------------------------|

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native `NDB` backup. This can be used for restoring a backup made from a cluster running (for example) NDB 7.6 to a cluster running NDB Cluster 7.5.

- `--slice-id=#`

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>--slice-id=#</code> |
| Introduced          | 5.7.29-ndb-7.6.13         |
| Type                | Integer                   |
| Default Value       | 0                         |
| Minimum Value       | 0                         |
| Maximum Value       | 1023                      |

When restoring by slices, this is the ID of the slice to restore. This option is always used together with `--num-slices`, and its value must be always less than that of `--num-slices`.

For more information, see the description of the `--num-slices` elsewhere in this section.

- `--tab=dir_name`, `-T dir_name`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--tab=dir_name</code> |
| Type                | Directory name              |

Causes `--print-data` to create dump files, one per table, each named `tbl_name.txt`. It requires as its argument the path to the directory where the files should be saved; use `.` for the current directory.

- `--usage`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--verbose=#`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--verbose=#</code> |
| Type                | Numeric                  |
| Default Value       | 1                        |
| Minimum Value       | 0                        |
| Maximum Value       | 255                      |

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

- `--version`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

Typical options for this utility are shown here:

```
ndb_restore [-c connection_string] -n node_id -b backup_id \
 [-m] -r --backup-path=/path/to/backup/files
```

Normally, when restoring from an NDB Cluster backup, `ndb_restore` requires at a minimum the `--nodeid` (short form: `-n`), `--backupid` (short form: `-b`), and `--backup-path` options. In addition, when `ndb_restore` is used to restore any tables containing unique indexes, you must include `--disable-indexes` or `--rebuild-indexes`. (Bug #57782, Bug #11764893)

The `-c` option is used to specify a connection string which tells `ndb_restore` where to locate the cluster management server (see [Section 21.3.3.3, “NDB Cluster Connection Strings”](#)). If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one `[api]` or `[mysqld]` section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty `[api]` or `[mysqld]` section in `config.ini` that is not being used for a MySQL server or other application for this reason (see [Section 21.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#)).

You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

**Error reporting.**

`ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may be able to recover from them, and reports `Restore successful, but encountered temporary error, please look at configuration` in such cases.

**Important**

After using `ndb_restore` to initialize an NDB Cluster for use in circular replication, binary logs on the SQL node acting as the replica are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a `SHOW TABLES` statement on that SQL node before running `START SLAVE`. This is a known issue in NDB Cluster.

**21.4.24.1 Restoring an NDB Backup to a Different Version of NDB Cluster**

The following two sections provide information about restoring a native NDB backup to a different version of NDB Cluster from the version in which the backup was taken.

In addition, you should consult [Section 21.2.7, “Upgrading and Downgrading NDB Cluster”](#), for other issues you may encounter when attempting to restore an NDB backup to a cluster running a different version of the NDB software.

It is also advisable to review [What is New in NDB Cluster 8.0](#), as well as [Section 2.11.3, “Changes in MySQL 5.7”](#), for other changes between NDB 8.0 and previous versions of NDB Cluster that may be relevant to your particular circumstances.

**Restoring an NDB backup to a previous version of NDB Cluster**

You may encounter issues when restoring a backup taken from a later version of NDB Cluster to a previous one, due to the use of features which do not exist in the earlier version. Some of these issues are listed here:

- Tables created in NDB 8.0 by default use the `utf8mb4_ai_ci` character set, which is not available in NDB 7.6 and earlier, and so cannot be read by an `ndb_restore` binary from one of these earlier versions. In such cases, it is necessary to alter any tables using `utf8mb4_ai_ci` so that they use a character set supported in the older version prior to performing the backup.
- Due to changes in how the MySQL Server and NDB handle table metadata, tables created or altered using the included MySQL server binary from NDB 8.0.14 or later cannot be restored using `ndb_restore` to an earlier version of NDB Cluster. Such tables use `.sdi` files which are not understood by older versions of `mysqld`.

A backup taken in NDB 8.0.14 or later of tables which were created in NDB 8.0.13 or earlier, and which have not been altered since upgrading to NDB 8.0.14 or later, should be restorable to older versions of NDB Cluster.

Since it is possible to restore metadata and table data separately, you can in such cases restore the table schemas from a dump made using `mysqldump`, or by executing the necessary `CREATE TABLE` statements manually, then import only the table data using `ndb_restore` with the `--restore-data` option.

- Encrypted backups created in NDB 8.0.22 and later cannot be restored using `ndb_restore` from NDB 8.0.21 or earlier.
- The `NDB_STORED_USER` privilege is not supported prior to NDB 8.0.18.
- NDB Cluster 8.0.18 and later supports up to 144 data nodes, while earlier versions support a maximum of only 48 data nodes. See [Restoring to Fewer Nodes Than the Original](#), for information with situations in which this incompatibility causes an issue.

## Restoring an NDB backup to a later version of NDB Cluster

In general, it should be possible to restore a backup created using the `ndb_mgm` client `START BACKUP` command in an older version of NDB to a newer version, provided that you use the `ndb_restore` binary that comes with the newer version. (It may be possible to use the older version of `ndb_restore`, but this is not recommended.) Additional potential issues are listed here:

- When restoring the metadata from a backup (`--restore-meta` option), `ndb_restore` normally attempts to reproduce the captured table schema exactly as it was when the backup was taken.
- Tables created in versions of NDB prior to 8.0.14 use `.frm` files for their metadata. These files can be read by the `mysqld` in NDB 8.0.14 and later, which can use the information contained therein to create the `.sdi` files used by the MySQL data dictionary in later versions.
- When restoring an older backup to a newer version of NDB, it may not be possible to take advantage of newer features such as hashmap partitioning, greater number of hashmap buckets, read backup, and different partitioning layouts. For this reason, it may be preferable to restore older schemas using `mysqldump` and the `mysql` client, which allows NDB to make use of the new schema features.
- Tables using the old temporal types which did not support fractional seconds (used prior to MySQL 5.6.4 and NDB 7.3.31) cannot be restored to NDB 8.0 using `ndb_restore`. You can check such tables using `CHECK TABLE`, and then upgrade them to the newer temporal column format, if necessary, using `REPAIR TABLE` in the `mysql` client; this must be done prior to taking the backup. See [Preparing Your Installation for Upgrade](#), for more information.

You also also restore such tables using a dump created with `mysqldump`.

- Distributed grant tables created in NDB 7.6 and earlier are not supported in NDB 8.0. Such tables can be restored to an NDB 8.0 cluster, but they have no effect on access control.

### 21.4.24.2 Restoring to a different number of data nodes

It is possible to restore from an NDB backup to a cluster having a different number of data nodes than the original from which the backup was taken. The following two sections discuss, respectively, the cases where the target cluster has a lesser or greater number of data nodes than the source of the backup.

#### Restoring to Fewer Nodes Than the Original

You can restore to a cluster having fewer data nodes than the original provided that the larger number of nodes is an even multiple of the smaller number. In the following example, we use a backup taken on a cluster having four data nodes to a cluster having two data nodes.

1. The management server for the original cluster is on host `host10`. The original cluster has four data nodes, with the node IDs and host names shown in the following extract from the management server's `config.ini` file:

```
[ndbd]
NodeId=2
HostName=host2

[ndbd]
NodeId=4
HostName=host4

[ndbd]
NodeId=6
HostName=host6

[ndbd]
NodeId=8
HostName=host8
```

We assume that each data node was originally started with `ndbmttd --ndb-connectstring=host10` or the equivalent.

2. Perform a backup in the normal manner. See [Section 21.5.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#), for information about how to do this.
3. The files created by the backup on each data node are listed here, where `N` is the node ID and `B` is the backup ID.
  - `BACKUP-B-0.N.Data`
  - `BACKUP-B.N.ctl`
  - `BACKUP-B.N.log`

These files are found under `BackupDataDir/BN/BACKUP-B`, on each data node. For the rest of this example, we assume that the backup ID is 1.

Have all of these files available for later copying to the new data nodes (where they can be accessed on the data node's local file system by `ndb_restore`). It is simplest to copy them all to a single location; we assume that this is what you have done.

4. The management server for the target cluster is on host `host20`, and the target has two data nodes, with the node IDs and host names shown, from the management server `config.ini` file on `host20`:

```
[ndbd]
NodeId=3
hostname=host3

[ndbd]
NodeId=5
hostname=host5
```

Each of the data node processes on `host3` and `host5` should be started with `ndbmttd -c host20 --initial` or the equivalent, so that the new (target) cluster starts with clean data node file systems.

5. Copy two different sets of two backup files to each of the target data nodes. For this example, copy the backup files from nodes 2 and 4 from the original cluster to node 3 in the target cluster. These files are listed here:

- `BACKUP-1-0.2.Data`
- `BACKUP-1.2.ctl`
- `BACKUP-1.2.log`
- `BACKUP-1-0.4.Data`
- `BACKUP-1.4.ctl`
- `BACKUP-1.4.log`

Then copy the backup files from nodes 6 and 8 to node 5; these files are shown in the following list:

- `BACKUP-1-0.6.Data`
- `BACKUP-1.6.ctl`
- `BACKUP-1.6.log`
- `BACKUP-1-0.8.Data`

- BACKUP-1.8.ctl
- BACKUP-1.8.log

For the remainder of this example, we assume that the respective backup files have been saved to the directory `/BACKUP-1` on each of nodes 3 and 5.

6. On each of the two target data nodes, you must restore from both sets of backups. First, restore the backups from nodes 2 and 4 to node 3 by invoking `ndb_restore` on `host3` as shown here:

```
shell> ndb_restore -c host20 --nodeid=2 --backupid=1 --restore-data --backup-path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=4 --backupid=1 --restore-data --backup-path=/BACKUP-1
```

Then restore the backups from nodes 6 and 8 to node 5 by invoking `ndb_restore` on `host5`, like this:

```
shell> ndb_restore -c host20 --nodeid=6 --backupid=1 --restore-data --backup-path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=8 --backupid=1 --restore-data --backup-path=/BACKUP-1
```

## Restoring to More Nodes Than the Original

The node ID specified for a given `ndb_restore` command is that of the node in the original backup and not that of the data node to restore it to. When performing a backup using the method described in this section, `ndb_restore` connects to the management server and obtains a list of data nodes in the cluster the backup is being restored to. The restored data is distributed accordingly, so that the number of nodes in the target cluster does not need to be known or calculated when performing the backup.

### Note

When changing the total number of LCP threads or LQH threads per node group, you should recreate the schema from backup created using `mysqldump`.

1. *Create the backup of the data.* You can do this by invoking the `ndb_mgm` client `START BACKUP` command from the system shell, like this:

```
shell> ndb_mgm -e "START BACKUP 1"
```

This assumes that the desired backup ID is 1.

2. Create a backup of the schema. In NDB 7.5.2 and later, this step is necessary only if the total number of LCP threads or LQH threads per node group is changed.

```
shell> mysqldump --no-data --routines --events --triggers --databases > myschema.sql
```

### Important

Once you have created the NDB native backup using `ndb_mgm`, you must not make any schema changes before creating the backup of the schema, if you do so.

3. Copy the backup directory to the new cluster. For example if the backup you want to restore has ID 1 and `BackupDataDir = /backups/node_nodeid`, then the path to the backup on this node is `/backups/node_1/BACKUP/BACKUP-1`. Inside this directory there are three files, listed here:

- BACKUP-1.0.1.Data
- BACKUP-1.1.ctl
- BACKUP-1.1.log

You should copy the entire directory to the new node.

If you needed to create a schema file, copy this to a location on an SQL node where it can be read by `mysqld`.

There is no requirement for the backup to be restored from a specific node or nodes.

To restore from the backup just created, perform the following steps:

1. *Restore the schema.*

- If you created a separate schema backup file using `mysqldump`, import this file using the `mysql` client, similar to what is shown here:

```
shell> mysql < myschema.sql
```

When importing the schema file, you may need to specify the `--user` and `--password` options (and possibly others) in addition to what is shown, in order for the `mysql` client to be able to connect to the MySQL server.

- If you did *not* need to create a schema file, you can re-create the schema using `ndb_restore --restore-meta` (short form `-m`), similar to what is shown here:

```
shell> ndb_restore --nodeid=1 --backupid=1 --restore-meta --backup-path=/backups/node_1/BACKUP/BACKUP
```

`ndb_restore` must be able to contact the management server; add the `--ndb-connectstring` option if and as needed to make this possible.

2. *Restore the data.* This needs to be done once for each data node in the original cluster, each time using that data node's node ID. Assuming that there were 4 data nodes originally, the set of commands required would look something like this:

```
ndb_restore --nodeid=1 --backupid=1 --restore-data --backup-path=/backups/node_1/BACKUP/BACKUP-1 --disable-indexes
ndb_restore --nodeid=2 --backupid=1 --restore-data --backup-path=/backups/node_2/BACKUP/BACKUP-1 --disable-indexes
ndb_restore --nodeid=3 --backupid=1 --restore-data --backup-path=/backups/node_3/BACKUP/BACKUP-1 --disable-indexes
ndb_restore --nodeid=4 --backupid=1 --restore-data --backup-path=/backups/node_4/BACKUP/BACKUP-1 --disable-indexes
```

These can be run in parallel.

Be sure to add the `--ndb-connectstring` option as needed.

3. *Rebuild the indexes.* These were disabled by the `--disable-indexes` option used in the commands just shown. Recreating the indexes avoids errors due to the restore not being consistent at all points. Rebuilding the indexes can also improve performance in some cases. To rebuild the indexes, execute the following command once, on a single node:

```
shell> ndb_restore --nodeid=1 --backupid=1 --backup-path=/backups/node_1/BACKUP/BACKUP-1 --rebuild-indexes
```

As mentioned previously, you may need to add the `--ndb-connectstring` option, so that `ndb_restore` can contact the management server.

## 21.4.25 `ndb_select_all` — Print Rows from an NDB Table

`ndb_select_all` prints all rows from an NDB table to `stdout`.

### Usage

```
ndb_select_all -c connection_string tbl_name -d db_name [> file_name]
```

Options that can be used with `ndb_select_all` are shown in the following table. Additional descriptions follow the table.

**Table 21.41 Command-line options used with the program `ndb_select_all`**

| <b>Format</b>                                    | <b>Description</b>                                                                 | <b>Added, Deprecated, or Removed</b>               |
|--------------------------------------------------|------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--character-sets-dir=path</code>           | Directory containing character sets                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retries=#</code>                 | Number of times to retry connection before giving up                               | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retry-delay=#</code>             | Number of seconds to wait between attempts to contact management server            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-string=connection-string,</code> | Same as --ndb-connectstring                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                  |                                                                                    |                                                    |
| <code>--core-file</code>                         | Write core file on error; used in debugging                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--database=dbname,</code>                  | Name of database in which table is found                                           | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-d</code>                                  |                                                                                    |                                                    |
| <code>--defaults-extra-file=path</code>          | Read given file after global files are read                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-file=path</code>                | Read default options from given file only                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-group-suffix=string</code>      | Also read groups with concat(group, suffix)                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--delimiter=char,</code>                   | Set column delimiter                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-D</code>                                  |                                                                                    |                                                    |
| <code>--descending,</code>                       | Sort resultset in descending order (requires --order)                              | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-z</code>                                  |                                                                                    |                                                    |
| <code>--disk</code>                              | Print disk references (useful only for Disk Data tables having nonindexed columns) | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--gci</code>                               | Include GCI in output                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--gci64</code>                             | Include GCI and row epoch in output                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--header,</code>                           | Print header (set to 0 FALSE to disable headers in output)                         | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-h</code>                                  |                                                                                    |                                                    |
| <code>--lock=#,</code>                           | Lock type                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-l</code>                                  |                                                                                    |                                                    |
| <code>--login-path=path</code>                   | Read given path from login file                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--help,</code>                             | Display help text and exit                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-?</code>                                  |                                                                                    |                                                    |

| Format                                       | Description                                                                                                                                              | Added, Deprecated, or Removed                      |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --ndb-connectstring=connection-string,<br>-c | Set connect string for connecting to ndb_mgmd.<br>Syntax: "[nodeid=id;]<br>[host=]hostname[:port]".<br>Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-mgmd-host=connection-string,<br>-c     | Same as --ndb-connectstring                                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-nodeid=#                               | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-optimized-node-selection               | Enable optimizations for selection of nodes for transactions.<br>Enabled by default; use --skip-ndb-optimized-node-selection to disable                  | (Supported in all NDB releases based on MySQL 5.7) |
| --no-defaults                                | Do not read default options from any option file other than login file                                                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| --nodata                                     | Do not print table column data                                                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --order=index,<br>-o                         | Sort resultset according to index having this name                                                                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| --parallelism=#,<br>-p                       | Degree of parallelism                                                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| --print-defaults                             | Print program argument list and exit                                                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --rowid                                      | Print row ID                                                                                                                                             | (Supported in all NDB releases based on MySQL 5.7) |
| --tupscan,                                   | Scan in tup order                                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| -t                                           |                                                                                                                                                          |                                                    |
| --usage,<br>-?                               | Display help text and exit; same as --help                                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| --useHexFormat,<br>-x                        | Output numbers in hexadecimal format                                                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --version,<br>-v                             | Display version information and exit                                                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- [--connect-retries](#)

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | 12                               |
| Minimum Value       | 0                                |
| Maximum Value       | 12                               |

Number of times to retry connection before giving up.

- [--connect-retry-delay](#)

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 5                                    |

Number of seconds to wait between attempts to contact management server.

- [--connect-string](#)

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | [none]                                          |

Same as [--ndb-connectstring](#).

- [--core-file](#)

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- [--database=dbname, -d dbname](#)

Name of the database in which the table is found. The default value is [TEST\\_DB](#).

- [--descending, -z](#)

Sorts the output in descending order. This option can be used only in conjunction with the [-o \(--order\)](#) option.

- [--defaults-extra-file](#)

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | [none]                                  |

Read given file after global files are read.

- [--defaults-file](#)

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |

|               |        |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | [none]                                      |

Also read groups with concat(group, suffix).

- `--delimiter=character, -D character`

Causes the `character` to be used as a column delimiter. Only table data columns are separated by this delimiter.

The default delimiter is the tab character.

- `--disk`

Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

- `--gci`

Adds a `GCI` column to the output showing the global checkpoint at which each row was last updated. See [Section 21.1, “NDB Cluster Overview”](#), and [Section 21.5.3.2, “NDB Cluster Log Events”](#), for more information about checkpoints.

- `--gci64`

Adds a `ROW$GCI64` column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--lock=lock_type, -l lock_type`

Employs a lock when reading the table. Possible values for `lock_type` are:

- `0`: Read lock
- `1`: Read lock with hold
- `2`: Exclusive read lock

There is no default value for this option.

- `--login-path`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type                | String                         |
| Default Value       | [none]                         |

Read given path from login file.

- `--header=FALSE`

Excludes column headers from the output.

- `--nodata`

Causes any table data to be omitted.

- `--ndb-connectstring`

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |
| Default Value       | <code>[none]</code>                                |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | <code>[none]</code>                            |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | <code>[none]</code>         |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--order=index_name, -o index_name`

Orders the output according to the index named `index_name`.

#### Note

This is the name of an index, not of a column; the index must have been explicitly named when created.

- `parallelism=#, -p #`

Specifies the degree of parallelism.

- `--print-defaults`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--rowid`

Adds a `ROWID` column providing information about the fragments in which rows are stored.

- `--tupscan, -t`

Scan the table in the order of the tuples.

- `--usage`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--useHexFormat -x`

Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- `--version`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

## Sample Output

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+---+-----+
| id | name |
+---+-----+
| 3 | shark |
| 6 | puffer |
| 2 | tuna |
| 4 | manta ray|
| 5 | grouper |
| 1 | guppy |
+---+-----+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id name
3 [shark]
6 [puffer]
2 [tuna]
4 [manta ray]
5 [grouper]
1 [guppy]
6 rows returned

NDBT_ProgramExit: 0 - OK
```

All string values are enclosed by square brackets ([ ... ]) in the output of `ndb_select_all`. For another example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (
```

```

 id INT(11) NOT NULL AUTO_INCREMENT,
 name VARCHAR(25) NOT NULL,
 breed VARCHAR(50) NOT NULL,
 PRIMARY KEY pk (id),
 KEY ix (name)
)
TABLESPACE ts STORAGE DISK
ENGINE=NDBCCLUSTER;

INSERT INTO dogs VALUES
 ('', 'Lassie', 'collie'),
 ('', 'Scooby-Doo', 'Great Dane'),
 ('', 'Rin-Tin-Tin', 'Alsatian'),
 ('', 'Rosscoe', 'Mutt');

```

This demonstrates the use of several additional `ndb_select_all` options:

```

shell> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI id name breed DISK_REF
834461 2 [Scooby-Doo] [Great Dane] [m_file_no: 0 m_page: 98 m_page_idx: 0]
834878 4 [Rosscoe] [Mutt] [m_file_no: 0 m_page: 98 m_page_idx: 16]
834463 3 [Rin-Tin-Tin] [Alsatian] [m_file_no: 0 m_page: 34 m_page_idx: 0]
835657 1 [Lassie] [Collie] [m_file_no: 0 m_page: 66 m_page_idx: 0]
4 rows returned

NDBT_ProgramExit: 0 - OK

```

## 21.4.26 ndb\_select\_count — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

### Usage

```
ndb_select_count [-c connection_string] -ddb_name tbl_name[, tbl_name2[, ...]]
```

Options that can be used with `ndb_select_count` are shown in the following table. Additional descriptions follow the table.

**Table 21.42 Command-line options used with the program `ndb_select_count`**

| Format                                       | Description                                                             | Added, Deprecated, or Removed                      |
|----------------------------------------------|-------------------------------------------------------------------------|----------------------------------------------------|
| --character-sets-dir= <i>path</i>            | Directory containing character sets                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --connect-retries=#                          | Number of times to retry connection before giving up                    | (Supported in all NDB releases based on MySQL 5.7) |
| --connect-retry-delay=#                      | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 5.7) |
| --connect-string= <i>connection_string</i> , | Same as --ndb-connectstring                                             | (Supported in all NDB releases based on MySQL 5.7) |
| -c                                           |                                                                         |                                                    |
| --core-file                                  | Write core file on error; used in debugging                             | (Supported in all NDB releases based on MySQL 5.7) |
| --database= <i>dbname</i> ,                  | Name of database in which table is found                                | (Supported in all NDB releases based on MySQL 5.7) |
| -d                                           |                                                                         |                                                    |

| Format                                    | Description                                                                                                                                     | Added, Deprecated, or Removed                      |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --defaults-extra-file=path                | Read given file after global files are read                                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-file=path                      | Read default options from given file only                                                                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-group-suffix=string            | Also read groups with concat(group, suffix)                                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --help,                                   | Display help text and exit                                                                                                                      | (Supported in all NDB releases based on MySQL 5.7) |
| -?                                        |                                                                                                                                                 |                                                    |
| --lock=#, -l                              | Lock type                                                                                                                                       | (Supported in all NDB releases based on MySQL 5.7) |
| --login-path=path                         | Read given path from login file                                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-connectstring=connection-string, -c | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;] [host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-mgmd-host=connection-string, -c     | Same as --ndb-connectstring                                                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-nodeid=#                            | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-optimized-node-selection            | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable            | (Supported in all NDB releases based on MySQL 5.7) |
| --no-defaults                             | Do not read default options from any option file other than login file                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| --parallelism=#, -p                       | Degree of parallelism                                                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --print-defaults                          | Print program argument list and exit                                                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| --usage, -?                               | Display help text and exit; same as --help                                                                                                      | (Supported in all NDB releases based on MySQL 5.7) |
| --version, -V                             | Display version information and exit                                                                                                            | (Supported in all NDB releases based on MySQL 5.7) |

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | 12                               |
| Minimum Value       | 0                                |
| Maximum Value       | 12                               |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 5                                    |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | [none]                                          |

Same as `--ndb-connectstring`.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | [none]                            |

Read default options from given file only.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | [none]                                  |

Read given file after global files are read.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |

|               |        |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

Also read groups with concat(group, suffix).

- [--login-path](#)

|                     |                   |
|---------------------|-------------------|
| Command-Line Format | --login-path=path |
| Type                | String            |
| Default Value       | [none]            |

Read given path from login file.

- [--help](#)

|                     |        |
|---------------------|--------|
| Command-Line Format | --help |
|---------------------|--------|

Display help text and exit.

- [--ndb-connectstring](#)

|                     |                                       |
|---------------------|---------------------------------------|
| Command-Line Format | --ndb-connectstring=connection-string |
| Type                | String                                |
| Default Value       | [none]                                |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- [--ndb-mgmd-host](#)

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | --ndb-mgmd-host=connection-string |
| Type                | String                            |
| Default Value       | [none]                            |

Same as [--ndb-connectstring](#).

- [--ndb-optimized-node-selection](#)

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | --ndb-optimized-node-selection |
|---------------------|--------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use [--skip-ndb-optimized-node-selection](#) to disable.

- [--ndb-nodeid](#)

|                     |                |
|---------------------|----------------|
| Command-Line Format | --ndb-nodeid=# |
| Type                | Integer        |
| Default Value       | [none]         |

Set node ID for this node, overriding any ID set by [--ndb-connectstring](#).

- [--no-defaults](#)

|                     |               |
|---------------------|---------------|
| Command-Line Format | --no-defaults |
|---------------------|---------------|

Do not read default options from any option file other than login file.

- [--print-defaults](#)

|                     |                  |
|---------------------|------------------|
| Command-Line Format | --print-defaults |
|---------------------|------------------|

Print program argument list and exit.

- --usage

|                     |         |
|---------------------|---------|
| Command-Line Format | --usage |
|---------------------|---------|

Display help text and exit; same as --help.

- --version

|                     |           |
|---------------------|-----------|
| Command-Line Format | --version |
|---------------------|-----------|

Display version information and exit.

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

## Sample Output

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs

NDBT_ProgramExit: 0 - OK
```

## 21.4.27 ndb\_setup.py — Start browser-based Auto-Installer for NDB Cluster (DEPRECATED)

### Note

This feature is deprecated and should be avoided. It is subject to removal in a future version of NDB Cluster.

`ndb_setup.py` starts the NDB Cluster Auto-Installer and opens the installer's Start page in the default Web browser.

### Important

This program is intended to be invoked as a normal user, and not with the `mysql`, system `root` or other administrative account.

This section describes usage of and program options for the command-line tool only. For information about using the Auto-Installer GUI that is spawned when `ndb_setup.py` is invoked, see [Section 21.2.8, “The NDB Cluster Auto-Installer \(NDB 7.5\) \(No longer supported\)”.](#)

## Usage

All platforms:

```
ndb_setup.py [options]
```

Additionally, on Windows platforms only:

```
setup.bat [options]
```

The following table includes all options that are supported by the NDB Cluster installation and configuration program `ndb_setup.py`. Additional descriptions follow the table.

**Table 21.43 Command-line options used with the program `ndb_setup.py`**

| Format                                      | Description                                                                                  | Added, Deprecated, or Removed                      |
|---------------------------------------------|----------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--browser-start-page=filename,</code> | Page that web browser opens when starting                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-s</code>                             |                                                                                              |                                                    |
| <code>--ca-certs-file=filename,</code>      | File containing list of client certificates allowed to connect to server                     | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-a</code>                             |                                                                                              |                                                    |
| <code>--cert-file=filename,</code>          | File containing X509 certificate identifying server                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                             |                                                                                              |                                                    |
| <code>--debug-level=level,</code>           | Python logging module debug level; one of DEBUG, INFO, WARNING (default), ERROR, or CRITICAL | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--help,</code>                        | Print help message                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-h</code>                             |                                                                                              |                                                    |
| <code>--key-file=file,</code>               | Specify file containing private key (if not included in --cert-file)                         | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-k</code>                             |                                                                                              |                                                    |
| <code>--no-browser,</code>                  | Do not open start page in browser, merely start tool                                         | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-n</code>                             |                                                                                              |                                                    |
| <code>--port=#, -p</code>                   | Specify port used by web server                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--server-log-file=file,</code>        | Log requests to this file; use '-' to force logging to stderr instead                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-o</code>                             |                                                                                              |                                                    |
| <code>--server-name=name,</code>            | Name of server to connect to                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-N</code>                             |                                                                                              |                                                    |
| <code>--use-http,</code>                    | Use unencrypted (HTTP) client/server connection                                              | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-H</code>                             |                                                                                              |                                                    |
| <code>--use-https,</code>                   | Use encrypted (HTTPS) client/server connection                                               | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-S</code>                             |                                                                                              |                                                    |

- `--browser-start-page=file, -s`

|                     |                                            |
|---------------------|--------------------------------------------|
| Command-Line Format | <code>--browser-start-page=filename</code> |
| Type                | String                                     |
| Default Value       | <code>index.html</code>                    |

Specify the file to open in the browser as the installation and configuration Start page. The default is `index.html`.

- `--ca-certs-file=file, -a`

|                     |                                       |
|---------------------|---------------------------------------|
| Command-Line Format | <code>--ca-certs-file=filename</code> |
| Type                | File name                             |
| Default Value       | [none]                                |

Specify a file containing a list of client certificates which are allowed to connect to the server. The default is an empty string, which means that no client authentication is used.

- `--cert-file=file, -c`

|                     |                                           |
|---------------------|-------------------------------------------|
| Command-Line Format | <code>--cert-file=filename</code>         |
| Type                | File name                                 |
| Default Value       | <code>/usr/share/mysql/mcc/cfg.pem</code> |

Specify a file containing an X.509 certificate which identifies the server. It is possible for the certificate to be self-signed. The default is `cfg.pem`.

- `--debug-level=level, -d`

|                     |                                                                                                                |
|---------------------|----------------------------------------------------------------------------------------------------------------|
| Command-Line Format | <code>--debug-level=level</code>                                                                               |
| Type                | Enumeration                                                                                                    |
| Default Value       | <code>WARNING</code>                                                                                           |
| Valid Values        | <code>WARNING</code><br><code>DEBUG</code><br><code>INFO</code><br><code>ERROR</code><br><code>CRITICAL</code> |

Set the Python logging module debug level. This is one of `DEBUG`, `INFO`, `WARNING`, `ERROR`, or `CRITICAL`. `WARNING` is the default.

- `--help, -h`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Print a help message.

- `--key-file=file, -d`

|                     |                              |
|---------------------|------------------------------|
| Command-Line Format | <code>--key-file=file</code> |
| Type                | File name                    |
| Default Value       | [none]                       |

Specify a file containing the private key if this is not included in the X.509 certificate file (`--cert-file`). The default is an empty string, which means that no such file is used.

- `--no-browser, -n`

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>--no-browser</code> |
|---------------------|---------------------------|

Start the installation and configuration tool, but do not open the Start page in a browser.

- `--port=#, -p`

|                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>--port=#</code> |
| Type                | Numeric               |
| Default Value       | 8081                  |
| Minimum Value       | 1                     |
| Maximum Value       | 65535                 |

Set the port used by the web server. The default is 8081.

- `--server-log-file=file`, `-o`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--server-log-file=file</code>             |
| Type                | File name                                       |
| Default Value       | <code>ndb_setup.log</code>                      |
| Valid Values        | <code>ndb_setup.log</code><br>- (Log to stderr) |

Log requests to this file. The default is `ndb_setup.log`. To specify logging to `stderr`, rather than to a file, use a `-` (dash character) for the file name.

- `--server-name=host`, `-N`

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | <code>--server-name=name</code> |
| Type                | String                          |
| Default Value       | <code>localhost</code>          |

Specify the host name or IP address for the browser to use when connecting. The default is `localhost`.

- `--use-http`, `-H`

|                     |                         |
|---------------------|-------------------------|
| Command-Line Format | <code>--use-http</code> |
|---------------------|-------------------------|

Make the browser use HTTP to connect with the server. This means that the connection is unencrypted and not secured in any way.

This option was added in NDB 7.6.

- `--use-https`, `-S`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--use-https</code> |
|---------------------|--------------------------|

Make the browser use a secure (HTTPS) connection with the server.

## 21.4.28 ndb\_show\_tables — Display List of NDB Tables

`ndb_show_tables` displays a list of all NDB database objects in the cluster. By default, this includes not only both user-created tables and NDB system tables, but NDB-specific indexes, internal triggers, and NDB Cluster Disk Data objects as well.

Options that can be used with `ndb_show_tables` are shown in the following table. Additional descriptions follow the table.

**Table 21.44 Command-line options used with the program `ndb_show_tables`**

| <b>Format</b>                                       | <b>Description</b>                                                                                                                                 | <b>Added, Deprecated, or Removed</b>               |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--character-sets-dir=path</code>              | Directory containing character sets                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retries=#</code>                    | Number of times to retry connection before giving up                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-retry-delay=#</code>                | Number of seconds to wait between attempts to contact management server                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--connect-string=connection-string,</code>    | Same as --ndb-connectstring                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     |                                                                                                                                                    |                                                    |
| <code>--core-file</code>                            | Write core file on error; used in debugging                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--database=string,</code>                     | Specifies database in which table is found; database name must be followed by table name                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-d</code>                                     |                                                                                                                                                    |                                                    |
| <code>--defaults-extra-file=path</code>             | Read given file after global files are read                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-file=path</code>                   | Read default options from given file only                                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-group-suffix=string</code>         | Also read groups with concat(group, suffix)                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--login-path=path</code>                      | Read given path from login file                                                                                                                    | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--loops=#,</code>                             | Number of times to repeat output                                                                                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-l</code>                                     |                                                                                                                                                    |                                                    |
| <code>--help,</code>                                | Display help text and exit                                                                                                                         | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-?</code>                                     |                                                                                                                                                    |                                                    |
| <code>--ndb-connectstring=connection-string,</code> | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;]<br>[host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     |                                                                                                                                                    |                                                    |
| <code>--ndb-mgmd-host=connection-string,</code>     | Same as --ndb-connectstring                                                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>-c</code>                                     |                                                                                                                                                    |                                                    |
| <code>--ndb-nodeid=#</code>                         | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--ndb-optimized-node-selection</code>         | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-                                                      | (Supported in all NDB releases based on MySQL 5.7) |

| Format               | Description                                                                                                                    | Added, Deprecated, or Removed                      |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --no-defaults        | ndb-optimized-node-selection to disable                                                                                        | (Supported in all NDB releases based on MySQL 5.7) |
| --parsable,<br>-p    | Do not read default options from any option file other than login file<br>Return output suitable for MySQL LOAD DATA statement | (Supported in all NDB releases based on MySQL 5.7) |
| --print-defaults     | Print program argument list and exit                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --show-temp-status   | Show table temporary flag                                                                                                      | (Supported in all NDB releases based on MySQL 5.7) |
| --type=#,<br>-t      | Limit output to objects of this type                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --unqualified,<br>-u | Do not qualify table names                                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --usage,<br>-?       | Display help text and exit; same as --help                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --version,<br>-v     | Display version information and exit                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |

## Usage

```
ndb_show_tables [-c connection_string]
```

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | 12                               |
| Minimum Value       | 0                                |
| Maximum Value       | 12                               |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 5                                    |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | <code>[none]</code>                             |

Same as `--ndb-connectstring`.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database, -d`

Specifies the name of the database in which the desired table is found. If this option is given, the name of a table must follow the database name.

If this option has not been specified, and no tables are found in the `TEST_DB` database, `ndb_show_tables` issues a warning.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | <code>[none]</code>                     |

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | <code>[none]</code>               |

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | <code>[none]</code>                         |

Also read groups with concat(group, suffix).

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

- [--login-path](#)

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type                | String                         |
| Default Value       | [none]                         |

Read given path from login file.

- [--loops, -l](#)

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- [--ndb-connectstring](#)

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |
| Default Value       | [none]                                             |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- [--ndb-mgmd-host](#)

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | [none]                                         |

Same as [--ndb-connectstring](#).

- [--ndb-nodeid](#)

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | [none]                      |

Set node ID for this node, overriding any ID set by [--ndb-connectstring](#).

- [--ndb-optimized-node-selection](#)

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use [--skip-ndb-optimized-node-selection](#) to disable.

- [--no-defaults](#)

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- [--parsable, -p](#)

---

Using this option causes the output to be in a format suitable for use with [LOAD DATA](#).

- `--print-defaults`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--show-temp-status`

If specified, this causes temporary tables to be displayed.

- `--type`, `-t`

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- 1: System table
- 2: User-created table
- 3: Unique hash index

Any other value causes all `NDB` database objects to be listed (the default).

- `--unqualified`, `-u`

If specified, this causes unqualified object names to be displayed.

- `--usage`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--version`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

#### Note

Only user-created NDB Cluster tables may be accessed from MySQL; system tables such as `SYSTAB_0` are not visible to `mysqld`. However, you can examine the contents of system tables using `NDB` API applications such as `ndb_select_all` (see Section 21.4.25, “`ndb_select_all` — Print Rows from an NDB Table”).

Prior to NDB 7.5.18 and 7.6.14, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the `NDBT` testing library. This dependency is has now been removed, eliminating the extraneous output.

## 21.4.29 `ndb_size.pl` — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the `NDBCLUSTER` storage engine. Unlike the other utilities discussed in this section, it does not require access to an NDB Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

### Requirements

- A running MySQL server. The server instance does not have to provide support for NDB Cluster.

- A working installation of Perl.
- The `DBI` module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using `GRANT USAGE ON db_name.*`—where `db_name` is the name of the database to be examined—is sufficient for this purpose.

`ndb_size.pl` can also be found in the MySQL sources in `storage/ndb/tools`.

Options that can be used with `ndb_size.pl` are shown in the following table. Additional descriptions follow the table.

**Table 21.45 Command-line options used with the program `ndb_size.pl`**

| Format                                | Description                                                                                                  | Added, Deprecated, or Removed                      |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <code>--database=dbname</code>        | Database or databases to examine; a comma-delimited list; default is ALL (use all databases found on server) | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--hostname[:port]</code>        | Specify host and optional port as host[:port]                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--socket=file_name</code>       | Specify socket to connect to                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--user=string</code>            | Specify MySQL user name                                                                                      | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--password=string</code>        | Specify MySQL user password                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--format=string</code>          | Set output format (text or HTML)                                                                             | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--excludetables=tbl_list</code> | Skip any tables in comma-separated list                                                                      | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--excludedbs=db_list</code>     | Skip any databases in comma-separated list                                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--savequeries=file</code>       | Saves all queries on database into file specified                                                            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--loadqueries=file</code>       | Loads all queries from file specified; does not connect to database                                          | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--real_table_name=table</code>  | Designates table to handle unique index size calculations                                                    | (Supported in all NDB releases based on MySQL 5.7) |

## Usage

```
perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] \
 [--user=user] [--password=password] \
 [--help|-h] [--format={html|text}] \
 [--loadqueries=file_name] [--savequeries=file_name]
```

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the `--database` option; the default behavior can be made explicit by using `ALL` for the name of the database. You can also exclude one or more databases by using the `--excludedbs` option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the

optional `--excludetables` option. A host name can be specified using `--hostname`; the default is `localhost`. You can specify a port in addition to the host using `host:port` format for the value of `--hostname`. The default port number is 3306. If necessary, you can also specify a socket; the default is `/var/lib/mysql.sock`. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the `--format` option; this can take either of the values `html` or `text`, with `text` being the default. An example of the text output is shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)

Connected to: DBI:mysql:host=localhost;mysql_socket=/tmp/mysql.sock

Including information for versions: 4.1, 5.0, 5.1

test.t1

DataMemory for Columns (* means varsized DataMemory):
 Column Name Type Varsized Key 4.1 5.0 5.1

|                |      |   |   |   |
|----------------|------|---|---|---|
| NoOfAttributes | 1000 | 3 | 3 | 3 |
| NoOfTriggers   | 768  | 5 | 5 | 5 |

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using `--savequeries`; a file containing such arrays to be read during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.)

The output from this script includes the following information:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The `IndexMemory` and `DataMemory` required per table and table row.

## 21.4.30 ndb\_top — View CPU usage information for NDB threads

`ndb_top` displays running information in the terminal about CPU usage by NDB threads on an NDB Cluster data node. Each thread is represented by two rows in the output, the first showing system statistics, the second showing the measured statistics for the thread.

`ndb_top` is available beginning with MySQL NDB Cluster 7.6.3.

### Usage

```
ndb_top [-h hostname] [-t port] [-u user] [-p pass] [-n node_id]
```

`ndb_top` connects to a MySQL Server running as an SQL node of the cluster. By default, it attempts to connect to a `mysqld` running on `localhost` and port 3306, as the MySQL `root` user with no password specified. You can override the default host and port using, respectively, `--host (-h)` and `--port (-t)`. To specify a MySQL user and password, use the `--user (-u)` and `--passwd (-p)` options. This user must be able to read tables in the `ndbinfo` database (`ndb_top` uses information from `ndbinfo.cpustat` and related tables).

For more information about MySQL user accounts and passwords, see [Section 6.2, “Access Control and Account Management”](#).

Output is available as plain text or an ASCII graph; you can specify this using the `--text (-x)` and `--graph (-g)` options, respectively. These two display modes provide the same information; they can be used concurrently. At least one display mode must be in use.

Color display of the graph is supported and enabled by default (`--color` or `-c` option). With color support enabled, the graph display shows OS user time in blue, OS system time in green, and idle time as blank. For measured load, blue is used for execution time, yellow for send time, red for time spent in send buffer full waits, and blank spaces for idle time. The percentage shown in the graph display is the sum of percentages for all threads which are not idle. Colors are not currently configurable; you can use grayscale instead by using `--skip-color`.

The sorted view (`--sort`, `-r`) is based on the maximum of the measured load and the load reported by the OS. Display of these can be enabled and disabled using the `--measured-load (-m)` and `--os-load (-o)` options. Display of at least one of these loads must be enabled.

The program tries to obtain statistics from a data node having the node ID given by the `--node-id (-n)` option; if unspecified, this is 1. `ndb_top` cannot provide information about other types of nodes.

The view adjusts itself to the height and width of the terminal window; the minimum supported width is 76 characters.

Once started, `ndb_top` runs continuously until forced to exit; you can quit the program using `Ctrl-C`. The display updates once per second; to set a different delay interval, use `--sleep-time (-s)`.

#### Note

`ndb_top` is available on macOS, Linux, and Solaris. It is not currently supported on Windows platforms.

The following table includes all options that are specific to the NDB Cluster program `ndb_top`. Additional descriptions follow the table.

**Table 21.46 Command-line options used with the program `ndb_top`**

| Format                                                  | Description                                                            | Added, Deprecated, or Removed                      |
|---------------------------------------------------------|------------------------------------------------------------------------|----------------------------------------------------|
| <code>--color</code> ,<br><code>-c</code>               | Show ASCII graphs in color; use <code>--skip-colors</code> to disable  | ADDED: NDB 7.6.3                                   |
| <code>--defaults-extra-file=path</code>                 | Read given file after global files are read                            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-file=path</code>                       | Read default options from given file only                              | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--defaults-group-suffix=string</code>             | Also read groups with concat(group, suffix)                            | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--graph</code> ,<br><code>-g</code>               | Display data using graphs; use <code>--skip-graphs</code> to disable   | ADDED: NDB 7.6.3                                   |
| <code>--help</code>                                     | Show program usage information                                         | ADDED: NDB 7.6.3                                   |
| <code>--host[=name]</code> ,<br><code>-h</code>         | Host name or IP address of MySQL Server to connect to                  | ADDED: NDB 7.6.3                                   |
| <code>--login-path=path</code>                          | Read given path from login file                                        | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--measured-load</code> ,<br><code>-m</code>       | Show measured load by thread                                           | ADDED: NDB 7.6.3                                   |
| <code>--no-defaults</code>                              | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.7) |
| <code>--node-id[=#]</code> ,<br><code>-n</code>         | Watch node having this node ID                                         | ADDED: NDB 7.6.3                                   |
| <code>--os-load</code> ,<br><code>-o</code>             | Show load measured by operating system                                 | ADDED: NDB 7.6.3                                   |
| <code>--passwd[=password]</code> ,<br><code>-p</code>   | Connect using this password (same as <code>--password</code> option)   | ADDED: NDB 7.6.3                                   |
| <code>--password[=password]</code> ,<br><code>-p</code> | Connect using this password                                            | REMOVED: NDB 7.6.4<br>ADDED: NDB 7.6.6             |

| Format                                       | Description                                        | Added, Deprecated, or Removed                      |
|----------------------------------------------|----------------------------------------------------|----------------------------------------------------|
| --port[=#],<br>-t (<=7.6.5),<br>-P (>=7.6.6) | Port number to use when connecting to MySQL Server | ADDED: NDB 7.6.3                                   |
| --print-defaults                             | Print program argument list and exit               | (Supported in all NDB releases based on MySQL 5.7) |
| --sleep-time[=seconds],<br>-s                | Time to wait between display refreshes, in seconds | ADDED: NDB 7.6.3                                   |
| --socket,<br>-S                              | Socket file to use for connection                  | ADDED: NDB 7.6.6                                   |
| --sort,<br>-r                                | Sort threads by usage; use --skip-sort to disable  | ADDED: NDB 7.6.3                                   |
| --text,<br>-x (<=7.6.5),<br>-t (>=7.6.6)     | Display data using text                            | ADDED: NDB 7.6.3                                   |
| --usage                                      | Show program usage information; same as --help     | ADDED: NDB 7.6.3                                   |
| --user[=name],<br>-u                         | Connect as this MySQL user                         | ADDED: NDB 7.6.3                                   |

## Additional Options

- `--color, -c`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--color</code> |
| Introduced          | 5.7.19-ndb-7.6.3     |
| Type                | Boolean              |
| Default Value       | <code>TRUE</code>    |

Show ASCII graphs in color; use `--skip-colors` to disable.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | <code>[none]</code>                     |

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | <code>[none]</code>               |

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | <code>[none]</code>                         |

Also read groups with concat(group, suffix).

- `--graph, -g`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--graph</code> |
| Introduced          | 5.7.19-ndb-7.6.3     |
| Type                | Boolean              |
| Default Value       | <code>TRUE</code>    |

Display data using graphs; use `--skip-graphs` to disable. This option or `--text` must be true; both options may be true.

- `--help, -?`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
| Introduced          | 5.7.19-ndb-7.6.3    |
| Type                | Boolean             |
| Default Value       | <code>TRUE</code>   |

Show program usage information.

- `--host [=name], -h`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--host [=name]</code> |
| Introduced          | 5.7.19-ndb-7.6.3            |
| Type                | String                      |
| Default Value       | <code>localhost</code>      |

Host name or IP address of MySQL Server to connect to.

- `--login-path`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type                | String                         |
| Default Value       | <code>[none]</code>            |

Read given path from login file.

- `--measured-load, -m`

|                     |                              |
|---------------------|------------------------------|
| Command-Line Format | <code>--measured-load</code> |
| Introduced          | 5.7.19-ndb-7.6.3             |
| Type                | Boolean                      |
| Default Value       | <code>FALSE</code>           |

Show measured load by thread. This option or [--os-load](#) must be true; both options may be true.

- [--no-defaults](#)

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <a href="#">--no-defaults</a> |
|---------------------|-------------------------------|

Do not read default options from any option file other than login file.

- [--node-id\[=#\]](#), [-n](#)

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <a href="#">--node-id[=#]</a> |
| Introduced          | 5.7.19-ndb-7.6.3              |
| Type                | Integer                       |
| Default Value       | <a href="#">1</a>             |

Watch the data node having this node ID.

- [--os-load](#), [-o](#)

|                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <a href="#">--os-load</a> |
| Introduced          | 5.7.19-ndb-7.6.3          |
| Type                | Boolean                   |
| Default Value       | <a href="#">TRUE</a>      |

Show load measured by operating system. This option or [--measured-load](#) must be true; both options may be true.

- [--passwd\[=password\]](#), [-p](#)

|                     |                                     |
|---------------------|-------------------------------------|
| Command-Line Format | <a href="#">--passwd[=password]</a> |
| Introduced          | 5.7.19-ndb-7.6.3                    |
| Removed             | 5.7.20-ndb-7.6.4                    |
| Type                | Boolean                             |
| Default Value       | <a href="#">NULL</a>                |

Connect to a MySQL Server using this password and the MySQL user specified by [--user](#).  
Synonym for [--password](#).

This password is associated with a MySQL user account only, and is not related in any way to the password used with encrypted [NDB](#) backups.

- [--password\[=password\]](#), [-p](#)

|                     |                                       |
|---------------------|---------------------------------------|
| Command-Line Format | <a href="#">--password[=password]</a> |
| Introduced          | 5.7.22-ndb-7.6.6                      |
| Type                | Boolean                               |
| Default Value       | <a href="#">NULL</a>                  |

Connect to a MySQL Server using this password and the MySQL user specified by [--user](#).

This password is associated with a MySQL user account only, and is not related in any way to the password used with encrypted [NDB](#) backups.

- [--port\[=#\]](#), [-P](#)

|                     |                         |
|---------------------|-------------------------|
| Command-Line Format | <code>--port[=#]</code> |
| Introduced          | 5.7.19-ndb-7.6.3        |
| Type                | Integer                 |
| Default Value       | 3306                    |

Port number to use when connecting to MySQL Server.

(Formerly, the short form for this option was `-t`, which was repurposed as the short form of `--text`.)

- `--print-defaults`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--sleep-time[=seconds]`, `-s`

|                     |                                     |
|---------------------|-------------------------------------|
| Command-Line Format | <code>--sleep-time[=seconds]</code> |
| Introduced          | 5.7.19-ndb-7.6.3                    |
| Type                | Integer                             |
| Default Value       | 1                                   |

Time to wait between display refreshes, in seconds.

- `--socket=path/to/file`, `-S`

|                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>--socket</code> |
| Introduced          | 5.7.22-ndb-7.6.6      |
| Type                | Path name             |
| Default Value       | [none]                |

Use the specified socket file for the connection.

- `--sort`, `-r`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--sort</code> |
| Introduced          | 5.7.19-ndb-7.6.3    |
| Type                | Boolean             |
| Default Value       | TRUE                |

Sort threads by usage; use `--skip-sort` to disable.

- `--text`, `-t`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--text</code> |
| Introduced          | 5.7.19-ndb-7.6.3    |
| Type                | Boolean             |
| Default Value       | FALSE               |

Display data using text. This option or `--graph` must be true; both options may be true.

(The short form for this option was `-x` in previous versions of NDB Cluster, but this is no longer supported.)

- [--usage](#)

|                     |                         |
|---------------------|-------------------------|
| Command-Line Format | <a href="#">--usage</a> |
| Introduced          | 5.7.19-ndb-7.6.3        |
| Type                | Boolean                 |
| Default Value       | <a href="#">TRUE</a>    |

Display help text and exit; same as [--help](#).

- [--user\[=name\]](#), [-u](#)

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <a href="#">--user[=name]</a> |
| Introduced          | 5.7.19-ndb-7.6.3              |
| Type                | String                        |
| Default Value       | <a href="#">root</a>          |

Connect as this MySQL user. Normally requires a password supplied by the [--password](#) option.

**Sample Output.** The next figure shows [ndb\\_top](#) running in a terminal window on a Linux system with an [ndbmttd](#) data node under a moderate load. Here, the program has been invoked using [ndb\\_top -n8 -x](#) to provide both text and graph output:

**Figure 21.38** [ndb\\_top](#) Running in Terminal

### 21.4.31 [ndb\\_waiter](#) — Wait for NDB Cluster to Reach a Given Status

[ndb\\_waiter](#) repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the [--timeout](#) limit is exceeded, then exits. By default, it waits for the cluster to achieve [STARTED](#) status, in which all nodes have started and connected to the cluster. This can be overridden using the [--no-contact](#) and [--not-started](#) options.

The node states reported by this utility are as follows:

- [NO\\_CONTACT](#): The node cannot be contacted.
- [UNKNOWN](#): The node can be contacted, but its status is not yet known. Usually, this means that the node has received a [START](#) or [RESTART](#) command from the management server, but has not yet acted on it.

- **NOT\_STARTED**: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's **RESTART** command.
- **STARTING**: The node's **ndbd** process has started, but the node has not yet joined the cluster.
- **STARTED**: The node is operational, and has joined the cluster.
- **SHUTTING\_DOWN**: The node is shutting down.
- **SINGLE\_USER\_MODE**: This is shown for all cluster data nodes when the cluster is in single user mode.

Options that can be used with **ndb\_waiter** are shown in the following table. Additional descriptions follow the table.

**Table 21.47 Command-line options used with the program **ndb\_waiter****

| Format                                 | Description                                                                                                                                                              | Added, Deprecated, or Removed                      |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --character-sets-dir=path              | Directory containing character sets                                                                                                                                      | (Supported in all NDB releases based on MySQL 5.7) |
| --connect-retries=#                    | Number of times to retry connection before giving up                                                                                                                     | (Supported in all NDB releases based on MySQL 5.7) |
| --connect-retry-delay=#                | Number of seconds to wait between attempts to contact management server                                                                                                  | (Supported in all NDB releases based on MySQL 5.7) |
| --connect-string=connection-string,    | Same as --ndb-connectstring                                                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| -c                                     |                                                                                                                                                                          |                                                    |
| --core-file                            | Write core file on error; used in debugging                                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-extra-file=path             | Read given file after global files are read                                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-file=path                   | Read default options from given file only                                                                                                                                | (Supported in all NDB releases based on MySQL 5.7) |
| --defaults-group-suffix=string         | Also read groups with concat(group, suffix)                                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --help,                                | Display help text and exit                                                                                                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| -?                                     |                                                                                                                                                                          |                                                    |
| --login-path=path                      | Read given path from login file                                                                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-connectstring=connection-string, | Set connect string for connecting to <b>ndb_mgmd</b> . Syntax: "[nodeid=id;]<br>[host=]hostname[:port]". Overrides entries in <b>NDB_CONNECTSTRING</b> and <b>my.cnf</b> | (Supported in all NDB releases based on MySQL 5.7) |
| -c                                     |                                                                                                                                                                          |                                                    |
| --ndb-mgmd-host=connection-string,     | Same as --ndb-connectstring                                                                                                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| -c                                     |                                                                                                                                                                          |                                                    |

| Format                         | Description                                                                                                                          | Added, Deprecated, or Removed                      |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| --ndb-nodeid=#                 | Set node ID for this node, overriding any ID set by --ndb-connectstring                                                              | (Supported in all NDB releases based on MySQL 5.7) |
| --ndb-optimized-node-selection | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.7) |
| --no-contact,<br>-n            | Wait for cluster to reach NO CONTACT state                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --no-defaults                  | Do not read default options from any option file other than login file                                                               | (Supported in all NDB releases based on MySQL 5.7) |
| --not-started                  | Wait for cluster to reach NOT STARTED state                                                                                          | (Supported in all NDB releases based on MySQL 5.7) |
| --nowait-nodes=list            | List of nodes not to be waited for                                                                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| --print-defaults               | Print program argument list and exit                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| --single-user                  | Wait for cluster to enter single user mode                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --timeout=#,<br>-t             | Wait this many seconds, then exit whether or not cluster has reached desired state                                                   | (Supported in all NDB releases based on MySQL 5.7) |
| --usage,<br>-?                 | Display help text and exit; same as --help                                                                                           | (Supported in all NDB releases based on MySQL 5.7) |
| --version,<br>-V               | Display version information and exit                                                                                                 | (Supported in all NDB releases based on MySQL 5.7) |
| --wait-nodes=list,<br>-w       | List of nodes to be waited for                                                                                                       | (Supported in all NDB releases based on MySQL 5.7) |

## Usage

```
ndb_waiter [-c connection_string]
```

## Additional Options

- `--character-sets-dir`

|                     |                                        |
|---------------------|----------------------------------------|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|----------------------------------------|

Directory containing character sets.

- `--connect-retries`

|                     |                                  |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type                | Integer                          |
| Default Value       | 12                               |
| Minimum Value       | 0                                |

|               |    |
|---------------|----|
| Maximum Value | 12 |
|---------------|----|

Number of times to retry connection before giving up.

- `--connect-retry-delay`

|                     |                                      |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type                | Integer                              |
| Default Value       | 5                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 5                                    |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

|                     |                                                 |
|---------------------|-------------------------------------------------|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type                | String                                          |
| Default Value       | [none]                                          |

Same as `--ndb-connectstring`.

- `--core-file`

|                     |                          |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--defaults-extra-file`

|                     |                                         |
|---------------------|-----------------------------------------|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type                | String                                  |
| Default Value       | [none]                                  |

Read given file after global files are read.

- `--defaults-file`

|                     |                                   |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type                | String                            |
| Default Value       | [none]                            |

Read default options from given file only.

- `--defaults-group-suffix`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type                | String                                      |
| Default Value       | [none]                                      |

Also read groups with concat(group, suffix).

- `--login-path`

|                     |                                |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
|---------------------|--------------------------------|

|               |        |
|---------------|--------|
| Type          | String |
| Default Value | [none] |

Read given path from login file.

- `--help`

|                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--ndb-connectstring`

|                     |                                                    |
|---------------------|----------------------------------------------------|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type                | String                                             |
| Default Value       | [none]                                             |

Set connect string for connecting to ndb\_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB\_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

|                     |                                                |
|---------------------|------------------------------------------------|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type                | String                                         |
| Default Value       | [none]                                         |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

|                     |                             |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type                | Integer                     |
| Default Value       | [none]                      |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

|                     |                                             |
|---------------------|---------------------------------------------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---------------------------------------------|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-contact, -n`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NO_CONTACT` status before exiting.

- `--no-defaults`

|                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--not-started`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NOT_STARTED` status before exiting.

- `--nowait-nodes=list`

When this option is used, `ndb_waiter` does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --nowait-nodes=1,3,7-9
```

#### Important

Do *not* use this option together with the `--wait-nodes` option.

- `--print-defaults`

|                     |                               |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--timeout=seconds, -t seconds`

Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- `--single-user`

The program waits for the cluster to enter single user mode.

- `--usage`

|                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--version`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

- `--wait-nodes=list, -w list`

When this option is used, `ndb_waiter` waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --wait-nodes=2,4-6,10
```

#### Important

Do *not* use this option together with the `--nowait-nodes` option.

**Sample Output.** Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by `...`) are omitted.

```
shell> ./ndb_waiter -c localhost
Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
```

```

...
State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED

...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...
State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...
State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED

```

### Note

If no connection string is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

Prior to NDB 7.5.18 and 7.6.14, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the `NDBT` testing library. This dependency has now been removed, eliminating the extraneous output.

## 21.5 Management of NDB Cluster

Managing an NDB Cluster involves a number of tasks, the first of which is to configure and start NDB Cluster. This is covered in [Section 21.3, “Configuration of NDB Cluster”](#), and [Section 21.4, “NDB Cluster Programs”](#).

The next few sections cover the management of a running NDB Cluster.

For information about security issues relating to management and deployment of an NDB Cluster, see [Section 21.5.17, “NDB Cluster Security Issues”](#).

There are essentially two methods of actively managing a running NDB Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement.

More detailed information about NDB Cluster operations is available in real time through an SQL interface using the `ndbinfo` database. For more information, see [Section 21.5.14, “ndbinfo: The NDB Cluster Information Database”](#).

NDB statistics counters provide improved monitoring using the `mysql` client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting `Ndb` objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by NDB Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

`mysqld` exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (`Ndb_api_`). The values of these variables can be read in the `mysql` client from the output of a `SHOW STATUS` statement, or by querying either the `SESSION_STATUS` table or the `GLOBAL_STATUS` table (in the `INFORMATION_SCHEMA` database). By comparing the values of the status variables before and after the execution of an SQL statement that acts on `NDB` tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of NDB Cluster.

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex NDB Cluster management tasks, such as starting, stopping, or restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to NDB Cluster. See [MySQL™ Cluster Manager 1.4.8 User Manual](#), for more information.

## 21.5.1 Commands in the NDB Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in [Section 21.5.3, “Event Reports Generated in NDB Cluster”](#); commands for creating backups and restoring from them are provided in [Section 21.5.8, “Online Backup of NDB Cluster”](#).

**Using `ndb_mgm` with MySQL Cluster Manager.** MySQL Cluster Manager handles starting and stopping processes and tracks their states internally, so it is not necessary to use `ndb_mgm` for these tasks for an NDB Cluster that is under MySQL Cluster Manager control. It is recommended *not* to use the `ndb_mgm` command-line client that comes with the NDB Cluster distribution to perform operations that involve starting or stopping nodes. These include but are not limited to the `START`, `STOP`, `RESTART`, and `SHUTDOWN` commands. For more information, see [MySQL Cluster Manager Process Commands](#).

The management client has the following basic commands. In the listing that follows, `node_id` denotes either a data node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- **HELP**

Displays information on all available commands.

- **CONNECT *connection-string***

Connects to the management server indicated by the connection string. If the client is already connected to this server, the client reconnects.

- **SHOW**

Displays information on the cluster's status. Possible node status values include `UNKNOWN`, `NO_CONTACT`, `NOT_STARTED`, `STARTING`, `STARTED`, `SHUTTING_DOWN`, and `RESTARTING`. The output from this command also indicates when the cluster is in single user mode (status `SINGLE USER MODE`).

- ***node\_id* START**

Brings online the data node identified by `node_id` (or all data nodes).

`ALL START` works on all data nodes only, and does not affect management nodes.

**Important**

To use this command to bring a data node online, the data node must have been started using `--nostart` or `-n`.

- ***node\_id* STOP [-a] [-f]**

Stops the data or management node identified by `node_id`.

**Note**

`ALL STOP` works to stop all data nodes only, and does not affect management nodes.

A node affected by this command disconnects from the cluster, and its associated `ndbd` or `ndb_mgmd` process terminates.

The `-a` option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

Normally, `STOP` fails if the result would cause an incomplete cluster. The `-f` option forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

**Warning**

Use of the `-a` option also disables the safety check otherwise performed when `STOP` is invoked to insure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the `-a` option with the `STOP` command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in `NDB`.

- ***node\_id* RESTART [-n] [-i] [-a] [-f]**

Restarts the data node identified by `node_id` (or all data nodes).

Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell.

**Note**

Backup files and Disk Data files are not removed when this option is used.

Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

Normally, `RESTART` fails if taking the node offline would result in an incomplete cluster. The `-f` option forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

- `node_id STATUS`

Displays status information for the data node identified by `node_id` (or for all data nodes).

The output from this command also indicates when the cluster is in single user mode.

- `node_id REPORT report-type`

Displays a report of type `report-type` for the data node identified by `node_id`, or for all data nodes using `ALL`.

Currently, there are three accepted values for `report-type`:

- `BackupStatus` provides a status report on a cluster backup in progress
- `MemoryUsage` displays how much data memory and index memory is being used by each data node as shown in this example:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
```

This information is also available from the `ndbinfo.memoryusage` table.

- `EventLog` reports events from the event log buffers of one or more data nodes.

`report-type` is case-insensitive and “fuzzy”; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.

- `ENTER SINGLE USER MODE node_id`

Enters single user mode, whereby only the MySQL server identified by the node ID `node_id` is permitted to access the database.

- [EXIT SINGLE USER MODE](#)

Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the database.

**Note**

It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

- [QUIT, EXIT](#)

Terminates the management client.

This command does not affect any nodes connected to the cluster.

- [SHUTDOWN](#)

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

- [CREATE NODEGROUP \*nodeid\[, nodeid, ...\]\*](#)

Creates a new NDB Cluster node group and causes data nodes to join it.

This command is used after adding new data nodes online to an NDB Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started, and that are to join the new node group. The list must contain no duplicate IDs; beginning with NDB 7.5.23 and NDB 7.6.19, the presence of any duplicates causes the command to return an error. The number of nodes in the list must be the same as the number of nodes in each node group that is already part of the cluster (each NDB Cluster node group must have the same number of nodes). In other words, if the NDB Cluster consists of 2 node groups having 2 data nodes each, then the new node group must also have 2 data nodes.

The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

For more information, see [Section 21.5.7, “Adding NDB Cluster Data Nodes Online”](#).

- [DROP NODEGROUP \*nodegroup\\_id\*](#)

Drops the NDB Cluster node group with the given `nodegroup_id`.

This command can be used to drop a node group from an NDB Cluster. `DROP NODEGROUP` takes as its sole argument the node group ID of the node group to be dropped.

`DROP NODEGROUP` acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client `SHOW` command with `no nodegroup` in place of the node group ID, like this (indicated using bold text):

```
id=3 @10.100.2.67 (5.7.33-ndb-7.5.23, no nodegroup)
```

`DROP NODEGROUP` works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using `ndb_mgm` or

the `mysql` client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because this removes only the table data; the data nodes continue to store an `NDBCLUSTER` table's definition until a `DROP TABLE` statement is issued that causes the table metadata to be dropped.

For more information about `DROP NODEGROUP`, see [Section 21.5.7, “Adding NDB Cluster Data Nodes Online”](#).

- `PROMPT [prompt]`

Changes the prompt shown by `ndb_mgm` to the string literal `prompt`.

`prompt` should not be quoted (unless you want the prompt to include the quotation marks). Unlike the case with the `mysql` client, special character sequences and escapes are not recognized. If called without an argument, the command resets the prompt to the default value (`ndb_mgm>`).

Some examples are shown here:

```
ndb_mgm> PROMPT mgm#1:
mgm#1: SHOW
Cluster Configuration
...
mgm#1: PROMPT mymgm >
mymgm > PROMPT 'mymgm:' '
'mymgm:' PROMPT mymgm:
mymgm: PROMPT
ndb_mgm> EXIT
jon@valhaj:~/bin>
```

Note that leading spaces and spaces within the `prompt` string are not trimmed. Trailing spaces are removed.

The `PROMPT` command was added in NDB 7.5.0.

- `node_id NODELOG DEBUG {ON|OFF}`

Toggles debug logging in the node log, as though the effected data node or nodes had been started with the `--verbose` option. `NODELOG DEBUG ON` starts debug logging; `NODELOG DEBUG OFF` switches debug logging off.

This command was added in NDB 7.6.4.

**Additional commands.** A number of other commands available in the `ndb_mgm` client are described elsewhere, as shown in the following list:

- `START BACKUP` is used to perform an online backup in the `ndb_mgm` client; the `ABORT BACKUP` command is used to cancel a backup already in progress. For more information, see [Section 21.5.8, “Online Backup of NDB Cluster”](#).
- The `CLUSTERLOG` command is used to perform various logging functions. See [Section 21.5.3, “Event Reports Generated in NDB Cluster”](#), for more information and examples. NDB 7.6.4 adds `NODELOG DEBUG` to activate or deactivate debug printouts in node logs, as described previously in this section.
- For testing and diagnostics work, the client supports a `DUMP` command which can be used to execute internal commands on the cluster. It should never be used in a production setting unless directed to do so by MySQL Support. For more information, see [MySQL NDB Cluster Internals Manual](#).

## 21.5.2 NDB Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on [NDB transporter errors](#).

### 21.5.2.1 NDB Cluster: Messages in the Cluster Log

The following table lists the most common [NDB](#) cluster log messages. For information about the cluster log, log events, and event types, see [Section 21.5.3, “Event Reports Generated in NDB Cluster”](#). These log messages also correspond to log event types in the MGM API; see [The Ndb\\_logevent\\_type Type](#), for related information of interest to Cluster API developers.

**Table 21.48 Common NDB cluster log messages**

| Log Message                                                                                   | Description                                                                                                                                                                        | Event Name          | Event Type | Priority | Severity |
|-----------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|------------|----------|----------|
| Node<br><i>mgm_node_id</i> :<br>Node<br><i>data_node_id</i><br>Connected                      | The data node having node ID <i>node_id</i> has connected to the management server (node <i>mgm_node_id</i> ).                                                                     | Connected           | Connection | 8        | INFO     |
| Node<br><i>mgm_node_id</i> :<br>Node<br><i>data_node_id</i><br>Disconnected                   | The data node having node ID <i>data_node_id</i> has disconnected from the management server (node <i>mgm_node_id</i> ).                                                           | Disconnected        | Connection | 8        | ALERT    |

### 21.5.2.2 NDB Cluster Log Startup Messages

Possible startup messages with descriptions are provided in the following list:

- Initial start, waiting for %s to connect, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting until nodes: %s connects, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting %u sec for nodes %s to connect, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]
- Waiting %u sec for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]
- Initial start with nodes %s [ missing: %s no-wait: %s ]
- Start with all nodes %s
- Start with nodes %s [ missing: %s no-wait: %s ]
- Start potentially partitioned with nodes %s [ missing: %s no-wait: %s ]
- Unknown startreport: 0x%x [ %s %s %s %s ]

### 21.5.2.3 Event Buffer Reporting in the Cluster Log

NDB uses one or more memory buffers for events received from the data nodes. There is one such buffer for each Ndb object subscribing to table events, which means that there are usually two buffers for each mysqld performing binary logging (one buffer for schema events, and one for data events). Each buffer contains epochs made up of events. These events consist of operation types (insert, update, delete) and row data (before and after images plus metadata).

NDB generates messages in the cluster log to describe the state of these buffers. Although these reports appear in the cluster log, they refer to buffers on API nodes (unlike most other cluster log messages, which are generated by data nodes). These messages and the data structures underlying them were changed significantly in NDB 7.5.1, with the addition of the NDB\_LE\_EventBufferStatus2 event type and the `ndb_logevent_EventBufferStatus2` data structure (see [The Ndb\\_logevent\\_type Type](#)). The remainder of this discussion focuses on the implementation based on `NDB_LE_EventBufferStatus2`.

Event buffer logging reports in the cluster log use the format shown here:

```
Node node_id: Event buffer status (object_id):
used=bytes_used (percent_used% of alloc)
alloc=bytes_allocated (percent_alloc% of max) max=bytes_available
latest_consumed_epoch=latest_consumed_epoch
latest_buffered_epoch=latest_buffered_epoch
report_reason=report_reason
```

The fields making up this report are listed here, with descriptions:

- *node\_id*: ID of the node where the report originated.
- *object\_id*: ID of the Ndb object where the report originated.
- *bytes\_used*: Number of bytes used by the buffer.
