- *percent\_used*: Percentage of allocated bytes used.
- *bytes\_allocated*: Number of bytes allocated to this buffer.
- *percent\_alloc*: Percentage of available bytes used; not printed if `ndb_eventbuffer_max_alloc` is equal to 0 (unlimited).
- *bytes\_available*: Number of bytes available; this is 0 if `ndb_eventbuffer_max_alloc` is 0 (unlimited).
- *latest\_consumed\_epoch*: The epoch most recently consumed to completion. (In NDB API applications, this is done by calling `nextEvent()`.)
- *latest\_buffered\_epoch*: The epoch most recently buffered (completely) in the event buffer.
- *report\_reason*: The reason for making the report. Possible reasons are shown later in this section.

The `latest_consumed_epoch` and `latest_buffered_epoch` fields correspond, respectively, to the `apply_gci` and `latest_gci` fields of the old-style event buffer logging messages used prior to NDB 7.5.1.

Possible reasons for reporting are described in the following list:

- ENOUGH\_EVENTBUFFER: The event buffer has sufficient space.

`LOW_FREE_EVENTBUFFER`: The event buffer is running low on free space.

The threshold free percentage level triggering these reports can be adjusted by setting the `ndb_report_thresh_binlog_mem_usage` server variable.

- **BUFFERED\_EPOCHS\_OVER\_THRESHOLD**: Whether the number of buffered epochs has exceeded the configured threshold. This number is the difference between the latest epoch that has been received in its entirety and the epoch that has most recently been consumed (in NDB API applications, this is done by calling `nextEvent()` or `nextEvent2()`). The report is generated every second until the number of buffered epochs goes below the threshold, which can be adjusted by setting the `ndb_report_thresh_binlog_epoch_slip` server variable. You can also adjust the threshold in NDB API applications by calling `setEventBufferQueueEmptyEpoch()`.
- **PARTIALLY\_DISCARDING**: Event buffer memory is exhausted—that is, 100% of `ndb_eventbuffer_max_alloc` has been used. Any partially buffered epoch is buffered to completion even if usage exceeds 100%, but any new epochs received are discarded. This means that a gap has occurred in the event stream.
- **COMPLETELY\_DISCARDING**: No epochs are buffered.
- **PARTIALLY\_BUFFERING**: The buffer free percentage following the gap has risen to the threshold, which can be set in the `mysql` client using the `ndb_eventbuffer_free_percent` server system variable or in NDB API applications by calling `set_eventbuffer_free_percent()`. New epochs are buffered. Epochs that could not be completed due to the gap are discarded.
- **COMPLETELY\_BUFFERING**: All epochs received are being buffered, which means that there is sufficient event buffer memory. The gap in the event stream has been closed.

#### 21.5.2.4 NDB Cluster: NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

|      |                                                                                                  |
|------|--------------------------------------------------------------------------------------------------|
| 0x00 | <b>TE_NO_ERROR</b><br>No error                                                                   |
| 0x01 | <b>TE_ERROR_CLOSING_SOCKET</b><br>Error found during closing of socket                           |
| 0x02 | <b>TE_ERROR_IN_SELECT_BEFORE_ACCEPT</b><br>Error found before accept. The transporter will retry |
| 0x03 | <b>TE_INVALID_MESSAGE_LENGTH</b><br>Error found in message (invalid message length)              |
| 0x04 | <b>TE_INVALID_CHECKSUM</b><br>Error found in message (checksum)                                  |
| 0x05 | <b>TE_COULD_NOT_CREATE_SOCKET</b><br>Error found while creating socket(can't create socket)      |
| 0x06 | <b>TE_COULD_NOT_BIND_SOCKET</b><br>Error found while binding server socket                       |
| 0x07 | <b>TE_LISTEN_FAILED</b><br>Error found while listening to server socket                          |
| 0x08 | <b>TE_ACCEPT_RETURN_ERROR</b>                                                                    |

|      |                                                           |
|------|-----------------------------------------------------------|
|      | Error found during accept(accept return error)            |
| 0x0b | <b>TE_SHM_DISCONNECT</b>                                  |
|      | The remote node has disconnected                          |
| 0x0c | <b>TE_SHM_IPC_STAT</b>                                    |
|      | Unable to check shm segment                               |
| 0x0d | <b>TE_SHM_UNABLE_TO_CREATE_SEGMENT</b>                    |
|      | Unable to create shm segment                              |
| 0x0e | <b>TE_SHM_UNABLE_TO_ATTACH_SEGMENT</b>                    |
|      | Unable to attach shm segment                              |
| 0x0f | <b>TE_SHM_UNABLE_TO_REMOVE_SEGMENT</b>                    |
|      | Unable to remove shm segment                              |
| 0x10 | <b>TE_TOO_SMALL_SIGID</b>                                 |
|      | Sig ID too small                                          |
| 0x11 | <b>TE_TOO_LARGE_SIGID</b>                                 |
|      | Sig ID too large                                          |
| 0x12 | <b>TE_WAIT_STACK_FULL</b>                                 |
|      | Wait stack was full                                       |
| 0x13 | <b>TE_RECEIVE_BUFFER_FULL</b>                             |
|      | Receive buffer was full                                   |
| 0x14 | <b>TE_SIGNAL_LOST_SEND_BUFFER_FULL</b>                    |
|      | Send buffer was full, and trying to force send fails      |
| 0x15 | <b>TE_SIGNAL_LOST</b>                                     |
|      | Send failed for unknown reason(signal lost)               |
| 0x16 | <b>TE_SEND_BUFFER_FULL</b>                                |
|      | The send buffer was full, but sleeping for a while solved |
| 0x21 | <b>TE_SHM_IPC_PERMANENT</b>                               |
|      | Shm ipc Permanent error                                   |

**Note**

Transporter error codes `0x17` through `0x20` and `0x22` are reserved for SCI connections, which are not supported in this version of NDB Cluster, and so are not included here.

### 21.5.3 Event Reports Generated in NDB Cluster

In this section, we discuss the types of event logs provided by NDB Cluster, and the types of events that are logged.

NDB Cluster provides two types of event log:

- The *cluster log*, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where `node_id` is the node ID of the management server) in the management server's `DataDir`.

Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See [Section 21.3.3.5, “Defining an NDB Cluster Management Server”](#), for more information about these parameters.

- *Node logs* are local to each node.

Output generated by node event logging is written to the file `ndb_node_id_out.log` (where `node_id` is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- *Category*: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.
- *Priority*: This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates “most important” and 15 “least important.”
- *Severity Level*: This can be any one of the following values: `ALERT`, `CRITICAL`, `ERROR`, `WARNING`, `INFO`, or `DEBUG`.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

|                                     |                                                         |
|-------------------------------------|---------------------------------------------------------|
| 2007-01-26 19:35:55 [MgmSrvr] INFO  | -- Node 1: Data usage is 2%(60 32K pages of total 2560) |
| 2007-01-26 19:35:55 [MgmSrvr] INFO  | -- Node 1: Index usage is 1%(24 8K pages of total 2336) |

| 2007-01-26 19:39:42 [MgmSrvr] INFO  | -- Node 1: Node 9 Connected                             |
| 2007-01-26 19:39:42 [MgmSrvr] INFO  | -- Node 1: Node 9: API 5.7.33-ndb-7.5.23                |
| 2007-01-26 19:39:42 [MgmSrvr] INFO  | -- Node 2: Node 9 Connected                             |
| 2007-01-26 19:39:42 [MgmSrvr] INFO  | -- Node 2: Node 9: API 5.7.33-ndb-7.5.23                |
| 2007-01-26 19:39:42 [MgmSrvr] INFO  | -- Node 3: Node 9 Connected                             |
| 2007-01-26 19:39:42 [MgmSrvr] INFO  | -- Node 3: Node 9: API 5.7.33-ndb-7.5.23                |
| 2007-01-26 19:39:42 [MgmSrvr] INFO  | -- Node 4: Node 9: API 5.7.33-ndb-7.5.23                |
| 2007-01-26 19:59:22 [MgmSrvr] ALERT | -- Node 2: Node 7 Disconnected                          |
| 2007-01-26 19:59:22 [MgmSrvr] ALERT | -- Node 2: Node 7 Disconnected                          |

Each line in the cluster log contains the following information:

- A timestamp in `YYYY-MM-DD HH:MM:SS` format.
- The type of node which is performing the logging. In the cluster log, this is always `[MgmSrvr]`.
- The severity of the event.
- The ID of the node reporting the event.
- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

### 21.5.3.1 NDB Cluster Logging Management Commands

`ndb_mgm` supports a number of management commands related to the cluster log and node logs. In the listing that follows, `node_id` denotes either a storage node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `CLUSTERLOG ON`

Turns the cluster log on.

- `CLUSTERLOG OFF`

Turns the cluster log off.

- `CLUSTERLOG INFO`

Provides information about cluster log settings.

- `node_id CLUSTERLOG category=threshold`

Logs `category` events with priority less than or equal to `threshold` in the cluster log.

- `CLUSTERLOG FILTER severity_level`

Toggles cluster logging of events of the specified `severity_level`.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

#### Note

Events are reported per data node, and that the threshold can be set to different values on different nodes.

**Table 21.49 Cluster log categories, with default threshold setting**

| Category    | Default threshold (All data nodes) |
|-------------|------------------------------------|
| STARTUP     | 7                                  |
| SHUTDOWN    | 7                                  |
| STATISTICS  | 7                                  |
| CHECKPOINT  | 7                                  |
| NODERESTART | 7                                  |
| CONNECTION  | 7                                  |
| ERROR       | 15                                 |
| INFO        | 7                                  |

The [STATISTICS](#) category can provide a great deal of useful data. See [Section 21.5.3.3, “Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client”](#), for more information.

Thresholds are used to filter events within each category. For example, a [STARTUP](#) event with a priority of 3 is not logged unless the threshold for [STARTUP](#) is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

#### Note

These correspond to Unix [syslog](#) levels, except for [LOG\\_EMERG](#) and [LOG\\_NOTICE](#), which are not used or mapped.

**Table 21.50 Event severity levels**

| Severity Level Value | Severity                 | Description                                                                           |
|----------------------|--------------------------|---------------------------------------------------------------------------------------|
| 1                    | <a href="#">ALERT</a>    | A condition that should be corrected immediately, such as a corrupted system database |
| 2                    | <a href="#">CRITICAL</a> | Critical conditions, such as device errors or insufficient resources                  |
| 3                    | <a href="#">ERROR</a>    | Conditions that should be corrected, such as configuration errors                     |
| 4                    | <a href="#">WARNING</a>  | Conditions that are not errors, but that might require special handling               |
| 5                    | <a href="#">INFO</a>     | Informational messages                                                                |
| 6                    | <a href="#">DEBUG</a>    | Debugging messages used for <a href="#">NDBCLUSTER</a> development                    |

Event severity levels can be turned on or off (using [CLUSTERLOG FILTER](#)—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

#### Important

Cluster log levels are set on a per [ndb\\_mgmd](#), per subscriber basis. This means that, in an NDB Cluster with multiple management servers, using a [CLUSTERLOG](#) command in an instance of [ndb\\_mgm](#) connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

### 21.5.3.2 NDB Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

## CONNECTION Events

These events are associated with connections between Cluster nodes.

**Table 21.51 Events associated with connections between cluster nodes**

| Event               | Priority | Severity Level | Description                             |
|---------------------|----------|----------------|-----------------------------------------|
| Connected           | 8        | INFO           | Data nodes connected                    |
| Disconnected        | 8        | ALERT          | Data nodes disconnected                 |
| CommunicationClosed | 8        | INFO           | SQL node or data node connection closed |
| CommunicationOpened | 8        | INFO           | SQL node or data node connection open   |
| ConnectedApiVersion | 8        | INFO           | Connection using API version            |

## CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

**Table 21.52 Events associated with checkpoints**

| Event                     | Priority | Severity Level | Description                                |
|---------------------------|----------|----------------|--------------------------------------------|
| GlobalCheckpointStarted   | 9        | INFO           | Start of GCP: REDO log is written to disk  |
| GlobalCheckpointCompleted | 10       | INFO           | GCP finished                               |
| LocalCheckpointStarted    | 7        | INFO           | Start of LCP: data written to disk         |
| LocalCheckpointCompleted  | 7        | INFO           | LCP completed normally                     |
| LCPStoppedInCalcKeepGci   | 0        | ALERT          | LCP stopped                                |
| LCPFragmetCompleted       | 11       | INFO           | LCP on a fragment has been completed       |
| UndoLogBlocked            | 7        | INFO           | UNDO logging blocked; buffer near overflow |
| RedoStatus                | 7        | INFO           | Redo status                                |

## STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

**Table 21.53 Events relating to the startup of a node or cluster**

| Event               | Priority | Severity Level | Description                                                                                                                                                       |
|---------------------|----------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NDBStartStarted     | 1        | INFO           | Data node start phases initiated (all nodes starting)                                                                                                             |
| NDBStartCompleted   | 1        | INFO           | Start phases completed, all data nodes                                                                                                                            |

## NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

**Table 21.54 Events relating to restarting a node**

| Event                 | Priority | Severity Level | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

**Table 21.55 Events of a statistical nature**

| Event                                | Priority | Severity Level | Description                                                                                                                                                      |
|--------------------------------------|----------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>TransReportCounters</code>     | 8        | INFO           | Report transaction statistics, including numbers of transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts |
| <code>OperationReportCounters</code> | 8        | INFO           | Number of operations                                                                                                                                             |
| <code>TableCreated</code>            | 7        | INFO           | Report number of tables created                                                                                                                                  |

| Event                 | Priority | Severity Level | Description                                               |
|-----------------------|----------|----------------|-----------------------------------------------------------|
| JobStatistic          | 9        | INFO           | Mean internal job scheduling statistics                   |
| ThreadConfigLoop      | 9        | INFO           | Number of thread configuration loops                      |
| SendBytesStatistic    | 9        | INFO           | Mean number of bytes sent to node <a href="#">X</a>       |
| ReceiveBytesStatistic | 9        | INFO           | Mean number of bytes received from node <a href="#">X</a> |
| MemoryUsage           | 5        | INFO           | Data and index memory usage (80%, 90%, and 100%)          |
| MTSignalStatistics    | 9        | INFO           | Multithreaded signals                                     |

## SCHEMA Events

These events relate to NDB Cluster schema operations.

**Table 21.56 Events relating to NDB Cluster schema operations**

| Event              | Priority | Severity Level | Description           |
|--------------------|----------|----------------|-----------------------|
| CreateSchemaObject | 8        | INFO           | Schema object created |
| AlterSchemaObject  | 8        | INFO           | Schema object updated |
| DropSchemaObject   | 8        | INFO           | Schema object dropped |

## ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

**Table 21.57 Events relating to cluster errors and warnings**

| Event              | Priority | Severity Level | Description                                                      |
|--------------------|----------|----------------|------------------------------------------------------------------|
| TransporterError   | 2        | ERROR          | Transporter error                                                |
| TransporterWarning | 8        | WARNING        | Transporter warning                                              |
| MissedHeartbeat    | 8        | WARNING        | Node <a href="#">X</a> missed heartbeat number <a href="#">Y</a> |
| DeadDueToHeartbeat | 8        | ALERT          | Node <a href="#">X</a> declared “dead” due to missed heartbeat   |
| WarningEvent       | 2        | WARNING        | General warning event                                            |
| SubscriptionStatus | 4        | WARNING        | Change in subscription status                                    |

## INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

**Table 21.58 Information events**

| Event              | Priority | Severity Level | Description                                                  |
|--------------------|----------|----------------|--------------------------------------------------------------|
| SentHeartbeat      | 12       | INFO           | Sent heartbeat                                               |
| CreateLogBytes     | 11       | INFO           | Create log: Log part, log file, size in MB                   |
| InfoEvent          | 2        | INFO           | General informational event                                  |
| EventBufferStatus  | 7        | INFO           | Event buffer status                                          |
| EventBufferStatus2 | 7        | INFO           | Improved event buffer status information; added in NDB 7.5.1 |

**Note**

`SentHeartbeat` events are available only if NDB Cluster was compiled with `VM_TRACE` enabled.

**SINGLEUSER Events**

These events are associated with entering and exiting single user mode.

**Table 21.59 Events relating to single user mode**

| Event                   | Priority | Severity Level | Description                          |
|-------------------------|----------|----------------|--------------------------------------|
| <code>SingleUser</code> | 7        | INFO           | Entering or exiting single user mode |

**BACKUP Events**

These events provide information about backups being created or restored.

**Table 21.60 Backup events**

| Event                            | Priority | Severity Level | Description                     |
|----------------------------------|----------|----------------|---------------------------------|
| <code>BackupStarted</code>       | 7        | INFO           | Backup started                  |
| <code>BackupStatus</code>        | 7        | INFO           | Backup status                   |
| <code>BackupCompleted</code>     | 7        | INFO           | Backup completed                |
| <code>BackupFailedToStart</code> | 7        | ALERT          | Backup failed to start          |
| <code>BackupAborted</code>       | 7        | ALERT          | Backup aborted by user          |
| <code>RestoreStarted</code>      | 7        | INFO           | Started restoring from backup   |
| <code>RestoreMetaData</code>     | 7        | INFO           | Restoring metadata              |
| <code>RestoreData</code>         | 7        | INFO           | Restoring data                  |
| <code>RestoreLog</code>          | 7        | INFO           | Restoring log files             |
| <code>RestoreCompleted</code>    | 7        | INFO           | Completed restoring from backup |
| <code>SavedEvent</code>          | 7        | INFO           | Event saved                     |

**21.5.3.3 Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client**

The `NDB` management client's `CLUSTERLOG STATISTICS` command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

**Transaction coordinator statistics.** Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- By supplying a data placement hint when the transaction is started

**Note**

You can determine which TC selection method is used for transactions started from a given SQL node using the `ndb_optimized_node_selection` system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

#### Note

Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for `Commit count` to be greater than `Trans count`.
- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—1 for the hidden unique index table, and 1 for the table on which the read takes place.
- **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval.
- **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

#### Note

A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero.

Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are *not* counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in `AttrInfoCount`.

- **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

The maximum value that `Concurrent Operations` can have is the maximum number of operations that a TC block can support; currently, this is  $(2 * \text{MaxNoOfConcurrentOperations}) + 16 + \text{MaxNoOfConcurrentTransactions}$ . (For more information about these configuration parameters, see the *Transaction Parameters* section of [Section 21.3.3.6, “Defining NDB Cluster Data Nodes”](#).)

- **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, `Abort count` can sometimes be greater than `Trans count`.
- **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).

- **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.
- **Local reads.** This is the number of primary-key read operations performed using a transaction coordinator on a node that also holds the primary fragment replica of the record. This count can also be obtained from the `LOCAL_READS` counter in the `ndbinfo.counters` table.
- **Local writes.** This contains the number of primary-key read operations that were performed using a transaction coordinator on a node that also holds the primary fragment replica of the record. This count can also be obtained from the `LOCAL_WRITES` counter in the `ndbinfo.counters` table.

**Local query handler statistics (Operations).** There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

#### Note

A single transaction may operate on data stored in multiple LQH blocks.

The `Operations` statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes. For example, in a cluster having two fragment replicas, the write to the primary fragment replica is recorded in the primary LQH, and the write to the backup is recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does *not* include local operations generated as a result of a table scan or ordered index scan, which are not counted.

**Process scheduler statistics.** In addition to the statistics reported by the transaction coordinator and local query handler, each `ndbd` process has a scheduler which also provides useful metrics relating to the performance of an NDB Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.
- **Mean send size and Mean receive size.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the `NDB` management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

#### Note

Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the NDB Cluster.

For more information about NDB Cluster management client commands relating to logging and reporting, see [Section 21.5.3.1, “NDB Cluster Logging Management Commands”](#).

## 21.5.4 Summary of NDB Cluster Start Phases

This section provides a simplified outline of the steps involved when NDB Cluster data nodes are started. More complete information can be found in [NDB Cluster Start Phases](#), in the [NDB Internals Guide](#).

These phases are the same as those reported in the output from the `node_id STATUS` command in the management client (see [Section 21.5.1, “Commands in the NDB Cluster Management Client”](#)). These start phases are also reported in the `start_phase` column of the `ndbinfo.nodes` table.

**Start types.** There are several different startup types and modes, as shown in the following list:

- **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

### Note

Disk Data files are not removed when restarting a node using `--initial`.

- **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.
- **Node restart.** This is the online restart of a cluster node while the cluster itself is running.
- **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

**Setup and initialization (phase -1).** Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The `NDBFS` and `NDBCNTR` blocks start. Data node file systems are cleared on those data nodes that were started with `--initial` option.
- **Phase 1.** In this stage, all remaining `NDB` kernel blocks are started. NDB Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

### Note

When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible

cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Phase 2.** The `NDBCNTR` kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.
- **Phase 3.** The `DBLQH` and `DBTC` kernel blocks set up communications between them. The startup type is determined; if this is a restart, the `DBDIH` block obtains permission to perform the restart.
- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFile`s.

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint.
- Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.
- **Phase 6.** In this phase, node groups are defined and set up.
- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as `Started`. It is now possible for API nodes (including SQL nodes) to connect to the cluster.
- **Phase 8.** If this is a system restart, all indexes are rebuilt (by `DBDIH`).
- **Phase 9.** The node internal startup variables are reset.
- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as `SUMA handover phase`.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

## 21.5.5 Performing a Rolling Restart of an NDB Cluster

This section discusses how to perform a *rolling restart* of an NDB Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

**Configuration change.**

To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

**NDB Cluster software upgrade or downgrade.** To upgrade the cluster to a newer version of the NDB Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of NDB Cluster).

**Change on node host.** To make changes in the hardware or operating system on which one or more NDB Cluster node processes are running.

**System reset (cluster reset).**

To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (`ndbd` or possibly `ndbmttd`) with the `--initial` option, which forces the data node to clear its file system and to reload all NDB Cluster data and metadata from the other data nodes.
- Create a backup using the `ndb_mgm` client `START BACKUP` command prior to performing the restart. Following the upgrade, restore the node or nodes using `ndb_restore`.

See [Section 21.5.8, “Online Backup of NDB Cluster”](#), and [Section 21.4.24, “`ndb\_restore` — Restore an NDB Cluster Backup”](#), for more information.

- Use `mysqldump` to create a backup prior to the upgrade; afterward, restore the dump using `LOAD DATA`.

**Resource Recovery.**

To free memory previously allocated to a table by successive `INSERT` and `DELETE` operations, for re-use by other NDB Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them. (See [Rolling restarts with multiple management servers](#).)
2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn.

Some node configuration parameters can be updated by issuing `RESTART` for each of the data nodes in the `ndb_mgm` client following the previous step. Other parameters require that the data node be stopped completely using the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndbmttd` executable as appropriate. (A shell command such as `kill` can also be used on most Unix systems to stop a data node process, but the `STOP` command is preferred and usually simpler.)

**Note**

On Windows, you can also use `SC STOP` and `SC START` commands, `NET STOP` and `NET START` commands, or the Windows Service Manager to stop and start nodes which have been installed as Windows services (see [Section 21.2.2.4, “Installing NDB Cluster Processes as Windows Services”](#)).

The type of restart required is indicated in the documentation for each node configuration parameter. See [Section 21.3.3, “NDB Cluster Configuration Files”](#).

3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

NDB Cluster supports a somewhat flexible order for upgrading nodes. When upgrading an NDB Cluster, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes,

data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different NDB Cluster releases is neither intended nor supported for continuous, long-term use in a production setting.
- All management nodes must be upgraded before any data nodes are upgraded. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.
- Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of NDB Cluster in general.)

It is not possible for any API node to perform schema operations (such as data definition statements) during a node restart. Due in part to this limitation, schema operations are also not supported during an online upgrade or downgrade.

**Rolling restarts with multiple management servers.** When performing a rolling restart of an NDB Cluster with multiple management nodes, you should keep in mind that `ndb_mgmd` checks to see if any other management node is running, and, if so, tries to use that node's configuration data. To keep this from occurring, and to force `ndb_mgmd` to re-read its configuration file, perform the following steps:

1. Stop all NDB Cluster `ndb_mgmd` processes.
2. Update all `config.ini` files.
3. Start a single `ndb_mgmd` with `--reload`, `--initial`, or both options as desired.
4. If you started the first `ndb_mgmd` with the `--initial` option, you must also start any remaining `ndb_mgmd` processes using `--initial`.

Regardless of any other options used when starting the first `ndb_mgmd`, you should not start any remaining `ndb_mgmd` processes after the first one using `--reload`.

5. Complete the rolling restarts of the data nodes and API nodes as normal.

When performing a rolling restart to update the cluster's configuration, you can use the `config_generation` column of the `ndbinfo.nodes` table to keep track of which data nodes have been successfully restarted with the new configuration. See [Section 21.5.14.28, “The ndbinfo nodes Table”](#).

## 21.5.6 NDB Cluster Single User Mode

*Single user mode* enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command in the `ndb_mgm` client to see when the cluster has entered single user mode. You can also check the `status` column of the `ndbinfo.nodes` table (see [Section 21.5.14.28, “The ndbinfo nodes Table”](#), for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is 5 becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node is rejected.

#### Note

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:

1. Finish all single user mode transactions
2. Issue the `EXIT SINGLE USER MODE` command
3. Restart the cluster's data nodes

- Method 2:

Restart storage nodes prior to entering single user mode.

## 21.5.7 Adding NDB Cluster Data Nodes Online

This section describes how to add NDB Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process.

#### Important

Currently, you must add new data nodes to an NDB Cluster as part of a new node group. In addition, it is not possible to change the number of fragment replicas (or the number of nodes per node group) online.

### 21.5.7.1 Adding NDB Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding NDB Cluster nodes online.

**Redistribution of Data.** The ability to add new nodes online includes a means to reorganize `NDBCLUSTER` table data and indexes so that they are distributed across all data nodes, including the new ones, by means of the `ALTER TABLE ... REORGANIZE PARTITION` statement. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed).

The redistribution for `NDBCLUSTER` tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

**Partial starts.** It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

**Effects on ongoing operations.** Normal DML operations using NDB Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

**Failure handling.** Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

**Table 21.61 Data node failure handling during node group creation and table reorganization**

| Failure during       | Failure in “Old” data node                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Failure in “New” data node                                                                                                                                                                                                                                                                                                                                                                                                                                                    | System Failure                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Failure during | Failure in “Old” data node           | Failure in “New” data node           | System Failure                                                                                                                                                               |
|----------------|--------------------------------------|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | table reorganization is rolled back. | table reorganization is rolled back. | <b>yet reached the internal commit point:</b> When the cluster is restarted, the data and indexes belonging to <i>table</i> are distributed using only the “old” data nodes. |

**Dropping node groups.** The `ndb_mgm` client supports a `DROP NODEGROUP` command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because the data nodes continue to store the table definitions.

### 21.5.7.2 Adding NDB Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to an NDB Cluster. This procedure applies whether you are using `ndbd` or `ndbmttd` binaries for the data node processes. For a more detailed example, see [Section 21.5.7.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”](#).

Assuming that you already have a running NDB Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. Perform a rolling restart of all NDB Cluster management servers.

#### Important

All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing NDB Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the NDB Cluster.

5. Start the new data nodes.

The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the NDB Cluster management client to create the new node group or node groups to which the new data nodes belong.
7. Redistribute the cluster's data among all data nodes, including the new ones. Normally this is done by issuing an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

*Exception:* For tables created using the `MAX_ROWS` option, this statement does not work; instead, use `ALTER TABLE ... ALGORITHM=INPLACE MAX_ROWS=...` to reorganize such tables. You should also bear in mind that using `MAX_ROWS` to set the number of partitions in this fashion is deprecated in NDB 7.5.4 and later, where you should use `PARTITION_BALANCE` instead; see [Section 13.1.18.9, “Setting NDB\\_TABLE Options”](#), for more information.

#### Note

This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized.

8. `ALTER TABLE ... REORGANIZE PARTITION ALGORITHM=INPLACE` reorganizes partitions but does not reclaim the space freed on the “old” nodes. You can do this by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

This works for space used by variable-width columns of in-memory NDB tables. `OPTIMIZE TABLE` is not supported for fixed-width columns of in-memory tables; it is also not supported for Disk Data tables.

You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster.

### 21.5.7.3 Adding NDB Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new NDB Cluster data nodes online, starting with an NDB Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

**Starting configuration.** For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[mgm]
HostName = 198.51.100.10
Id = 10
```

```
[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

### Note

We have left a gap in the sequence between data node IDs and other nodes. This makes it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=1 @198.51.100.1 (5.7.33-ndb-7.5.23, Nodegroup: 0, *)
id=2 @198.51.100.2 (5.7.33-ndb-7.5.23, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @198.51.100.10 (5.7.33-ndb-7.5.23)

[mysqld(API)] 2 node(s)
id=20 @198.51.100.20 (5.7.33-ndb-7.5.23)
id=21 @198.51.100.21 (5.7.33-ndb-7.5.23)
```

Finally, we assume that the cluster contains a single `NDBCLUSTER` table created as shown here:

```
USE n;

CREATE TABLE ips (
 id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 country_code CHAR(2) NOT NULL,
 type CHAR(4) NOT NULL,
 ip_address VARCHAR(15) NOT NULL,
 addresses BIGINT UNSIGNED DEFAULT NULL,
 date BIGINT UNSIGNED DEFAULT NULL
) ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

### Note

In this example, we show the single-threaded `ndbd` being used for the data node processes. You can also apply this example, if you are using the multithreaded `ndbmt` by substituting `ndbmt` for `ndbd` wherever it appears in the steps that follow.

**Step 1: Update configuration file.** Open the cluster global configuration file in a text editor and add `[ndbd]` sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 198.51.100.3 and 198.51.100.4, respectively.) After you have added the new sections, the contents of the `config.ini` file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
```

```

DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3

[ndbd]
Id = 4
HostName = 198.51.100.4

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21

```

Once you have made the necessary changes, save the file.

**Step 2: Restart the management server.** Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

```

ndb_mgm> 10 STOP
Node 10 has shut down.
Disconnecting to allow Management Server to shutdown

shell>

```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

```

shell> ndb_mgmd -f config.ini --reload
2008-12-08 17:29:23 [MgmSrvr] INFO -- NDB Cluster Management Server. 5.7.33-ndb-7.5.23
2008-12-08 17:29:23 [MgmSrvr] INFO -- Reading cluster configuration from 'config.ini'

```

If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

```

-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=1 @198.51.100.1 (5.7.33-ndb-7.5.23, Nodegroup: 0, *)
id=2 @198.51.100.2 (5.7.33-ndb-7.5.23, Nodegroup: 0)
id=3 (not connected, accepting connect from 198.51.100.3)
id=4 (not connected, accepting connect from 198.51.100.4)

```

```
[ndb_mgmd(MGM)] 1 node(s)
id=10 @198.51.100.10 (5.7.33-ndb-7.5.23)

[mysqld(API)] 2 node(s)
id=20 @198.51.100.20 (5.7.33-ndb-7.5.23)
id=21 @198.51.100.21 (5.7.33-ndb-7.5.23)
```

**Step 3: Perform a rolling restart of the existing data nodes.** This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 7.5.23)
Node 1: Started (version 7.5.23)

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted

ndb_mgm> Node 2: Start initiated (version 7.5.23)

ndb_mgm> Node 2: Started (version 7.5.23)
```

### Important

After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...)` before proceeding any further.

You can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

**Step 4: Perform a rolling restart of all cluster API nodes.** Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL `root` password for a given MySQL server instance:

```
shell> mysqladmin -uroot -ppassword shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=198.51.100.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

**Step 5: Perform an initial start of the new data nodes.** From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```
shell> ndbd -c 198.51.100.10 --initial
```

### Note

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

*Wait until both of the new data nodes have started before proceeding with the next step.* Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
```

```
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=1 @198.51.100.1 (5.7.33-ndb-7.5.23, Nodegroup: 0, *)
id=2 @198.51.100.2 (5.7.33-ndb-7.5.23, Nodegroup: 0)
id=3 @198.51.100.3 (5.7.33-ndb-7.5.23, no nodegroup)
id=4 @198.51.100.4 (5.7.33-ndb-7.5.23, no nodegroup)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @198.51.100.10 (5.7.33-ndb-7.5.23)

[mysqld(API)] 2 node(s)
id=20 @198.51.100.20 (5.7.33-ndb-7.5.23)
id=21 @198.51.100.21 (5.7.33-ndb-7.5.23)
```

**Step 6: Create a new node group.** You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=1 @198.51.100.1 (5.7.33-ndb-7.5.23, Nodegroup: 0, *)
id=2 @198.51.100.2 (5.7.33-ndb-7.5.23, Nodegroup: 0)
id=3 @198.51.100.3 (5.7.33-ndb-7.5.23, Nodegroup: 1)
id=4 @198.51.100.4 (5.7.33-ndb-7.5.23, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @198.51.100.10 (5.7.33-ndb-7.5.23)

[mysqld(API)] 2 node(s)
id=20 @198.51.100.20 (5.7.33-ndb-7.5.23)
id=21 @198.51.100.21 (5.7.33-ndb-7.5.23)
```

**Step 7: Redistribute cluster data.** When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the `Per partition info` section of the output, shown here in bold text):

```
shell> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --
Version: 1
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
```

```

Number of attributes: 6
Number of primary keys: 1
Length of frm data: 340
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex

-- Per partition info --
Partition Row count Commit count Frag fixed memory Frag varsized memory
0 26086 26086 1572864 557056
1 26329 26329 1605632 557056

NDBT_ProgramExit: 0 - OK

```

You can cause the data to be redistributed among all of the data nodes by performing, for each `NDB` table, an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client.

### Important

`ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` does not work on tables that were created with the `MAX_ROWS` option. Instead, use `ALTER TABLE ... ALGORITHM=INPLACE, MAX_ROWS=...` to reorganize such tables.

Keep in mind that using `MAX_ROWS` to set the number of partitions per table is deprecated in NDB 7.5.4 and later, where you should use `PARTITION_BALANCE` instead; see [Section 13.1.18.9, “Setting NDB\\_TABLE Options”](#), for more information.

After issuing the statement `ALTER TABLE ips ALGORITHM=INPLACE, REORGANIZE PARTITION`, you can see using `ndb_desc` that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```

shell> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --
Version: 16777217

3 13093 13093 819200 294912

NDBT_ProgramExit: 0 - OK

```

#### Note

Normally, `ALTER TABLE table_name [ALGORITHM=INPLACE, ] REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new NDB Cluster node group is an exception in this regard; when used in this way, no other keywords or identifiers follow `REORGANIZE PARTITION`.

For more information, see [Section 13.1.8, “ALTER TABLE Statement”](#).

In addition, for each table, the `ALTER TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the `INFORMATION_SCHEMA.TABLES` table:

```

SELECT TABLE_SCHEMA, TABLE_NAME
 FROM INFORMATION_SCHEMA.TABLES
 WHERE ENGINE = 'NDBCLUSTER';

```

#### Note

The `INFORMATION_SCHEMA.TABLES.ENGINE` value for an NDB Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```

ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)

```

#### Note

Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created *after* the new data nodes have been added; data added to such tables is

distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed *prior to* the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER TABLE ... REORGANIZE PARTITION`.

**Alternative procedure, without rolling restart.** It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3
Nodegroup = 65536

[ndbd]
Id = 4
HostName = 198.51.100.4
Nodegroup = 65536

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

The data nodes to be brought online at a later time (nodes 3 and 4) can be configured with `NodeGroup = 65536`, in which case nodes 1 and 2 can each be started as shown here:

```
shell> ndbd -c 198.51.100.10 --initial
```

The data nodes configured with `NodeGroup = 65536` are treated by the management server as though you had started nodes 1 and 2 using `--nowait-nodes=3,4` after waiting for a period of time determined by the setting for the `StartNoNodeGroupTimeout` data node configuration parameter. By default, this is 15 seconds (15000 milliseconds).

### Note

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

```
shell> ndbd -c 198.51.100.10 --initial
```

- 
2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

```
ndb_mgm> CREATE NODEGROUP 3,4
```

3. In the `mysql` client, issue `ALTER TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing NDB Cluster tables cannot use the new nodes for data distribution until this has been done.)

## 21.5.8 Online Backup of NDB Cluster

The next few sections describe how to prepare for and then to create an NDB Cluster backup using the functionality for this purpose found in the `ndb_mgm` management client. To distinguish this type of backup from a backup made using `mysqldump`, we sometimes refer to it as a “native” NDB Cluster backup. (For information about the creation of backups with `mysqldump`, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#).) Restoration of NDB Cluster backups is done using the `ndb_restore` utility provided with the NDB Cluster distribution; for information about `ndb_restore` and its use in restoring NDB Cluster backups, see [Section 21.4.24, “ndb\\_restore — Restore an NDB Cluster Backup”](#).

### 21.5.8.1 NDB Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-backup_id.node_id.ctl`

A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-backup_id-0.node_id.data`

A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-backup_id.node_id.log`

A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing just shown, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the file.

The location of the backup files is determined by the `BackupDataDir` parameter.

### 21.5.8.2 Using The NDB Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See [Section 21.5.8.3, “Configuration for NDB Cluster Backups”](#).)

The `START BACKUP` command is used to create a backup:

```
START BACKUP [backup_id] [wait_option] [snapshot_option]

wait_option:
WAIT {STARTED | COMPLETED} | NOWAIT

snapshot_option:
SNAPSHOTSTART | SNAPSHOTEND
```

Successive backups are automatically identified sequentially, so the `backup_id`, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing `backup_id` value is used, the backup fails with the error `Backup failed: file already exists`. If used, the `backup_id` must follow `START BACKUP` immediately, before any other options are used.

The `wait_option` can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

```
ndb_mgm> START BACKUP NOWAIT
ndb_mgm>
```

In this case, the management client can be used even while it prints progress information from the backup process.

- With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

```
ndb_mgm> START BACKUP WAIT STARTED
Waiting for started, this may take several minutes
Node 2: Backup 3 started from node 1
ndb_mgm>
```

- `WAIT COMPLETED` causes the management client to wait until the backup process is complete before returning control to the user.

`WAIT COMPLETED` is the default.

A `snapshot_option` can be used to determine whether the backup matches the state of the cluster when `START BACKUP` was issued, or when it was completed. `SNAPSHOTSTART` causes the backup to match the state of the cluster when the backup began; `SNAPSHOTEND` causes the backup to reflect the state of the cluster when the backup was finished. `SNAPSHOTEND` is the default, and matches the behavior found in previous NDB Cluster releases.

#### Note

If you use the `SNAPSHOTSTART` option with `START BACKUP`, and the `CompressedBackup` parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a `wait_option` and a `snapshot_option` are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Start the management client (`ndb_mgm`), if it not running already.

2. Execute the **START BACKUP** command. This produces several lines of output indicating the progress of the backup, as shown here:

```
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 2: Backup 1 started from node 1
Node 2: Backup 1 started from node 1 completed
 StartGCP: 177 StopGCP: 180
 #Records: 7362 #LogRecords: 0
 Data: 453648 bytes Log: 0 bytes
ndb_mgm>
```

3. When the backup has started the management client displays this message:

```
Backup backup_id started from node node_id
```

*backup\_id* is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. *node\_id* is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

```
Node 2: Backup 1 started from node 1
```

4. The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

As is the case for the notification that the backup has started, *backup\_id* is the unique identifier for this particular backup, and *node\_id* is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
 StartGCP: 177 StopGCP: 180
 #Records: 7362 #LogRecords: 0
 Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking **ndb\_mgm** with the **-e** or **--execute** option, as shown in this example:

```
shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using **START BACKUP** in this way, you must specify the backup ID.

Cluster backups are created by default in the **BACKUP** subdirectory of the **DataDir** on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the **config.ini** file using the **BackupDataDir** configuration parameter. The backup files created for a backup with a given *backup\_id* are stored in a subdirectory named **BACKUP-*backup\_id*** in the backup directory.

**Cancelling backups.** To cancel or abort a backup that is already in progress, perform the following steps:

1. Start the management client.
2. Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

The number *backup\_id* is the identifier of the backup that was included in the response of the management client when the backup was started (in the message **Backup *backup\_id* started from node *management\_node\_id***).

3. The management client acknowledges the abort request with `Abort of backup backup_id ordered.`

**Note**

At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client reports this fact in a manner similar to what is shown here:

```
Node 1: Backup 3 started from 5 has been aborted.
 Error: 1321 - Backup aborted by user request: Permanent error: User defined error
Node 3: Backup 3 started from 5 has been aborted.
 Error: 1323 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted.
 Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted.
 Error: 1323 - 1323: Permanent error: Internal error
```

In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

**Note**

There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

The `Backup backup_id started from node management_node_id has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

**Note**

If there is no backup having the ID `backup_id` running when an `ABORT BACKUP` is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

### 21.5.8.3 Configuration for NDB Cluster Backups

Five configuration parameters are essential for backup:

- `BackupDataBufferSize`

The amount of memory used to buffer data before it is written to disk.

- `BackupLogBufferSize`

The amount of memory used to buffer log records before these are written to disk.

- `BackupMemory`

The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- `BackupWriteSize`

The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- `BackupMaxWriteSize`

The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

In addition, `CompressedBackup` causes `NDB` to use compression when creating and writing to backup files.

More detailed information about these parameters can be found in [Backup Parameters](#).

You can also set a location for the backup files using the `BackupDataDir` configuration parameter. The default is `FileSystemPath/BACKUP/BACKUP-backup_id`.

#### 21.5.8.4 NDB Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

##### Important

If you have set `BackupDataBufferSize` and `BackupLogBufferSize` and their sum is greater than 4MB, then you must also set `BackupMemory` as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

`NDB` does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring an NDB Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

#### 21.5.9 MySQL Server Usage for NDB Cluster

`mysqld` is the traditional MySQL server process. To be used with NDB Cluster, `mysqld` needs to be built with support for the `NDB` storage engine, as it is in the precompiled binaries available from <https://dev.mysql.com/downloads/>. If you build MySQL from source, you must invoke `CMake` with the `-DWITH_NDBCLUSTER=1` option to include support for `NDB`.

For more information about compiling NDB Cluster from source, see [Section 21.2.1.4, “Building NDB Cluster from Source on Linux”](#), and [Section 21.2.2.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).

(For information about `mysqld` options and variables, in addition to those discussed in this section, which are relevant to NDB Cluster, see [Section 21.3.3.9, “MySQL Server Options and Variables for NDB Cluster”](#).)

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDBCLUSTER` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row

displayed in the output, you are not running an NDB-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connection string either on the command line when starting `mysqld` or in `my.cnf`. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See [Section 21.3.3.3, “NDB Cluster Connection Strings”](#), for more information on connection strings.

Given this information, the MySQL server can act as a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It is fully aware of all cluster data nodes as well as their status, and establishes connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
***** 1. row *****
 Id: 1
 User: system user
 Host:
 db:
Command: Daemon
 Time: 1
 State: Waiting for event from ndbcluster
 Info: NULL
```

### Important

To participate in an NDB Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with NDB tables, *nor is it possible to create any new tables regardless of storage engine*. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as NDB tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in an NDB Cluster, you must restart the server *without* the `--ndbcluster` option.

## 21.5.10 NDB Cluster Disk Data Tables

It is possible to store the nonindexed columns of NDB tables on disk, rather than in RAM.

As part of implementing NDB Cluster Disk Data work, a number of improvements were made in NDB Cluster for the efficient handling of very large amounts (terabytes) of data during node recovery and

restart. These include a “no-steal” algorithm for synchronizing a starting node with very large data sets. For more information, see the paper [Recovery Principles of NDB Cluster 5.1](#), by NDB Cluster developers Mikael Ronström and Jonas Orelund.

NDB Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see [NDB Cluster Disk Data configuration parameters](#) and [NDB Cluster Disk Data storage and GCP Stop errors](#)

The performance of an NDB Cluster that uses Disk Data storage can also be greatly improved by separating data node file systems from undo log files and tablespace data files, which can be done using symbolic links. For more information, see [Section 21.5.10.2, “Using Symbolic Links with Disk Data Objects”](#).

### 21.5.10.1 NDB Cluster Disk Data Objects

NDB Cluster Disk Data storage is implemented using a number of *Disk Data objects*. These include the following:

- *Tablespaces* act as containers for other Disk Data objects.
- *Undo log files* undo information required for rolling back transactions.
- One or more undo log files are assigned to a *log file group*, which is then assigned to a tablespace.
- *Data files* store Disk Data table data. A data file is assigned directly to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the NDB Cluster `config.ini` file, and where `node_id` is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

NDB Cluster tablespaces and log file groups are not implemented as files.

#### Important

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named `dd1`.

Assuming that you have already set up an NDB Cluster with all nodes (including management and SQL nodes), the basic steps for creating an NDB Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undofile*).

#### Note

Undo log files are necessary only for Disk Data tables; they are not used for `NDBCLUSTER` tables that are stored only in memory.

2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.
3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the `mysql` client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named `lg_1` using `CREATE LOGFILE GROUP`. This log file group is to be made up of two undo log files, which we name `undo_1.log` and `undo_2.log`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume

the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.log` to `lg_1` in this `CREATE LOGFILE GROUP` statement:

```
CREATE LOGFILE GROUP lg_1
 ADD UNDOFILE 'undo_1.log'
 INITIAL_SIZE 16M
 UNDO_BUFFER_SIZE 2M
 ENGINE NDBCLUSTER;
```

To add `undo_2.log` to the log file group, use the following `ALTER LOGFILE GROUP` statement:

```
ALTER LOGFILE GROUP lg_1
 ADD UNDOFILE 'undo_2.log'
 INITIAL_SIZE 12M
 ENGINE NDBCLUSTER;
```

Some items of note:

- The `.log` file extension used here is not required. We use it merely to make the log files easily recognizable.
- Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` option. The only permitted values for this option are `NDBCLUSTER` and `NDB`.

### Important

There can exist at most one log file group in the same NDB Cluster at any given time.

- When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER LOGFILE GROUP` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `undo_2.log` and each file is 12 MB in size.
  - `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.
  - For more information about the `CREATE LOGFILE GROUP` statement, see [Section 13.1.15, “CREATE LOGFILE GROUP Statement”](#). For more information about `ALTER LOGFILE GROUP`, see [Section 13.1.5, “ALTER LOGFILE GROUP Statement”](#).
2. Now we can create a tablespace, which contains files to be used by NDB Cluster Disk Data tables for storing their data. A tablespace is also associated with a particular log file group. When creating a new tablespace, you must specify the log file group which it is to use for undo logging; you must also specify a data file. You can add more data files to the tablespace after the tablespace is created; it is also possible to drop data files from a tablespace (an example of dropping data files is provided later in this section).

Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. This tablespace is to contain two data files named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
 ADD DATAFILE 'data_1.dat'
 USE LOGFILE GROUP lg_1
 INITIAL_SIZE 32M
 ENGINE NDBCLUSTER;

ALTER TABLESPACE ts_1
 ADD DATAFILE 'data_2.dat'
```

```
INITIAL_SIZE 48M
ENGINE NDBCLUSTER;
```

The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

Some items of note:

- As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition of data files.
- When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each data file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 data files, 1 each in the data directory of each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in size.
- NDB 7.6 (and later) reserves 4% of each tablespace for use during data node restarts. This space is not available for storing data.
- All `CREATE TABLESPACE` and `ALTER TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. For NDB Cluster tablespaces, the only permitted values for this option are `NDBCLUSTER` and `NDB`.
- For more information about the `CREATE TABLESPACE` and `ALTER TABLESPACE` statements, see [Section 13.1.19, “CREATE TABLESPACE Statement”](#), and [Section 13.1.9, “ALTER TABLESPACE Statement”](#).

3. Now it is possible to create a table whose nonindexed columns are stored on disk in the tablespace `ts_1`:

```
CREATE TABLE dt_1 (
 member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
 last_name VARCHAR(50) NOT NULL,
 first_name VARCHAR(50) NOT NULL,
 dob DATE NOT NULL,
 joined DATE NOT NULL,
 INDEX(last_name, first_name)
)
TABLESPACE ts_1 STORAGE DISK
ENGINE NDBCLUSTER;
```

The `TABLESPACE ... STORAGE DISK` option tells the `NDBCLUSTER` storage engine to use tablespace `ts_1` for disk data storage.

Once table `ts_1` has been created as shown, you can perform `INSERT`, `SELECT`, `UPDATE`, and `DELETE` statements on it just as you would with any other MySQL table.

It is also possible to specify whether an individual column is stored on disk or in memory by using a `STORAGE` clause as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. See [Section 13.1.18, “CREATE TABLE Statement”](#), for more information.

**Indexing of columns implicitly stored on disk.** For table `dt_1` as defined in the example just shown, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. Only nonindexed columns can be held on disk; indexes and indexed column data continue to be

stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

You cannot add an index to a column that has been explicitly declared `STORAGE DISK`, without first changing its storage type to `MEMORY`; any attempt to do so fails with an error. A column which *implicitly* uses disk storage can be indexed; when this is done, the column's storage type is changed to `MEMORY` automatically. By “implicitly”, we mean a column whose storage type is not declared, but which is which inherited from the parent table. In the following CREATE TABLE statement (using the tablespace `ts_1` defined previously), columns `c2` and `c3` use disk storage implicitly:

```
mysql> CREATE TABLE ti (
-> c1 INT PRIMARY KEY,
-> c2 INT,
-> c3 INT,
-> c4 INT
->)
-> STORAGE DISK
-> TABLESPACE ts_1
-> ENGINE NDBCLUSTER;
Query OK, 0 rows affected (1.31 sec)
```

Because `c2`, `c3`, and `c4` are themselves not declared with `STORAGE DISK`, it is possible to index them. Here, we add indexes to `c2` and `c3`, using, respectively, `CREATE INDEX` and `ALTER TABLE`:

```
mysql> CREATE INDEX i1 ON ti(c2);
Query OK, 0 rows affected (2.72 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> ALTER TABLE ti ADD INDEX i2(c3);
Query OK, 0 rows affected (0.92 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

`SHOW CREATE TABLE` confirms that the indexes were added.

```
mysql> SHOW CREATE TABLE ti\G
***** 1. row *****
 Table: ti
Create Table: CREATE TABLE `ti` (
 `c1` int(11) NOT NULL,
 `c2` int(11) DEFAULT NULL,
 `c3` int(11) DEFAULT NULL,
 `c4` int(11) DEFAULT NULL,
 PRIMARY KEY (`c1`),
 KEY `i1` (`c2`),
 KEY `i2` (`c3`)
) /*!50100 TABLESPACE `ts_1` STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

You can see using `ndb_desc` that the indexed columns (emphasized text) now use in-memory rather than on-disk storage:

```
shell> ./ndb_desc -d test t1
-- t1 --
Version: 33554433
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80

i2(c3) - OrderedIndex
PRIMARY(c1) - OrderedIndex
i1(c2) - OrderedIndex

NDBT_ProgramExit: 0 - OK

```

**Performance note.** The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You may use absolute and relative file system paths with [ADD UNDOFILE](#) and [ADD DATAFILE](#). Relative paths are calculated relative to the data node's data directory. You may also use symbolic links; see [Section 21.5.10.2, “Using Symbolic Links with Disk Data Objects”](#), for more information and examples.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. The same is true for dropping any of these objects:

- A log file group cannot be dropped as long as any tablespaces are using it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- It is not possible to drop files created in association with a different tablespace than the one with which the files were created. (Bug #20053)

For example, to drop all the objects created so far in this section, you would use the following statements:

```

mysql> DROP TABLE dt_1;

mysql> ALTER TABLESPACE ts_1
 -> DROP DATAFILE 'data_2.dat'
 -> ENGINE NDBCLUSTER;

mysql> ALTER TABLESPACE ts_1
 -> DROP DATAFILE 'data_1.dat'
 -> ENGINE NDBCLUSTER;

mysql> DROP TABLESPACE ts_1
 -> ENGINE NDBCLUSTER;

mysql> DROP LOGFILE GROUP lg_1
 -> ENGINE NDBCLUSTER;

```

These statements must be performed in the order shown, except that the two [ALTER TABLESPACE ... DROP DATAFILE](#) statements may be executed in either order.

You can obtain information about data files used by Disk Data tables by querying the [FILES](#) table in the [INFORMATION\\_SCHEMA](#) database. An extra “[NULL](#) row” provides additional information about undo

log files. For more information and examples, see [Section 24.3.9, “The INFORMATION\\_SCHEMA FILES Table”](#).

### 21.5.10.2 Using Symbolic Links with Disk Data Objects

The performance of an NDB Cluster that uses Disk Data storage can be greatly improved by separating the data node file system from any tablespace files (undo log files and data files), and placing these on different disks. In early versions of NDB Cluster, there was no direct support for this in NDB Cluster, and it was necessary to achieve this separation using symbolic links. NDB Cluster now supports the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`, which make the use of symbolic links for this purpose unnecessary. For more information about these parameters, see [Disk Data file system parameters](#).

### 21.5.10.3 NDB Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see [Section 11.7, “Data Type Storage Requirements”](#).

You can obtain an estimate the amount of space available in data files and undo log files by querying the `INFORMATION_SCHEMA.FILES` table. For more information and examples, see [Section 24.3.9, “The INFORMATION\\_SCHEMA FILES Table”](#).

#### Note

The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a `TEXT` or `BLOB` column are stored in memory; only the remainder is stored on disk.
- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of `DataMemory` used per row from 4 to 8 bytes.

#### Important

Starting the cluster with the `--initial` option does *not* remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that `DiskPageBufferMemory` is of sufficient size. You can query the `diskpagebuffer` table to help determine whether the value for this parameter needs to be increased.

### 21.5.11 Online Operations with ALTER TABLE in NDB Cluster

MySQL NDB Cluster 7.5 supports online table schema changes using the standard `ALTER TABLE` syntax employed by the MySQL Server (`ALGORITHM=DEFAULT | INPLACE | COPY`), and described elsewhere.

#### Note

Some older releases of NDB Cluster used a syntax specific to `NDB` for online `ALTER TABLE` operations. That syntax has since been removed.

Operations that add and drop indexes on variable-width columns of [NDB](#) tables occur online. Online operations are noncopying; that is, they do not require that indexes be re-created. They do not lock the table being altered from access by other API nodes in an NDB Cluster (but see [Limitations of NDB online operations](#), later in this section). Such operations do not require single user mode for [NDB](#) table alterations made in an NDB cluster with multiple API nodes; transactions can continue uninterrupted during online DDL operations.

`ALGORITHM=INPLACE` can be used to perform online `ADD COLUMN`, `ADD INDEX` (including `CREATE INDEX` statements), and `DROP INDEX` operations on [NDB](#) tables. Online renaming of [NDB](#) tables is also supported.

Currently you cannot add disk-based columns to [NDB](#) tables online. This means that, if you wish to add an in-memory column to an [NDB](#) table that uses a table-level `STORAGE DISK` option, you must declare the new column as using memory-based storage explicitly. For example—assuming that you have already created tablespace `ts1`—suppose that you create table `t1` as follows:

```
mysql> CREATE TABLE t1 (
 > c1 INT NOT NULL PRIMARY KEY,
 > c2 VARCHAR(30)
 >)
 > TABLESPACE ts1 STORAGE DISK
 > ENGINE NDB;
Query OK, 0 rows affected (1.73 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

You can add a new in-memory column to this table online as shown here:

```
mysql> ALTER TABLE t1
 > ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC STORAGE MEMORY,
 > ALGORITHM=INPLACE;
Query OK, 0 rows affected (1.25 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

This statement fails if the `STORAGE MEMORY` option is omitted:

```
mysql> ALTER TABLE t1
 > ADD COLUMN c4 INT COLUMN_FORMAT DYNAMIC,
 > ALGORITHM=INPLACE;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason:
Adding column(s) or add/reorganize partition not supported online. Try
ALGORITHM=COPY.
```

If you omit the `COLUMN_FORMAT DYNAMIC` option, the dynamic column format is employed automatically, but a warning is issued, as shown here:

```
mysql> ALTER ONLINE TABLE t1 ADD COLUMN c4 INT STORAGE MEMORY;
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW WARNINGS\G
***** 1. row *****
 Level: Warning
 Code: 1478
Message: DYNAMIC column c4 with STORAGE DISK is not supported, column will
become FIXED

mysql> SHOW CREATE TABLE t1\G
***** 1. row *****
 Table: t1
Create Table: CREATE TABLE `t1` (
 `c1` int(11) NOT NULL,
 `c2` varchar(30) DEFAULT NULL,
 `c3` int(11) /*!50606 STORAGE MEMORY */ /*!50606 COLUMN_FORMAT DYNAMIC */ DEFAULT NULL,
 `c4` int(11) /*!50606 STORAGE MEMORY */ DEFAULT NULL,
 PRIMARY KEY (`c1`)
) /*!50606 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.03 sec)
```

**Note**

The `STORAGE` and `COLUMN_FORMAT` keywords are supported only in NDB Cluster; in any other version of MySQL, attempting to use either of these keywords in a `CREATE TABLE` or `ALTER TABLE` statement results in an error.

It is also possible to use the statement `ALTER TABLE ... REORGANIZE PARTITION, ALGORITHM=INPLACE` with no `partition_names INTO (partition_definitions)` option on NDB tables. This can be used to redistribute NDB Cluster data among new data nodes that have been added to the cluster online. This does *not* perform any defragmentation, which requires an `OPTIMIZE TABLE` or null `ALTER TABLE` statement. For more information, see [Section 21.5.7, “Adding NDB Cluster Data Nodes Online”](#).

## Limitations of NDB online operations

Online `DROP COLUMN` operations are not supported.

Online `ALTER TABLE`, `CREATE INDEX`, or `DROP INDEX` statements that add columns or add or drop indexes are subject to the following limitations:

- A given online `ALTER TABLE` can use only one of `ADD COLUMN`, `ADD INDEX`, or `DROP INDEX`. One or more columns can be added online in a single statement; only one index may be created or dropped online in a single statement.
- The table being altered is not locked with respect to API nodes other than the one on which an online `ALTER TABLE ADD COLUMN`, `ADD INDEX`, or `DROP INDEX` operation (or `CREATE INDEX` or `DROP INDEX` statement) is run. However, the table is locked against any other operations originating on the *same* API node while the online operation is being executed.
- The table to be altered must have an explicit primary key; the hidden primary key created by the NDB storage engine is not sufficient for this purpose.
- The storage engine used by the table cannot be changed online.
- The tablespace used by the table cannot be changed online. (Bug #99269, Bug #31180526)
- When used with NDB Cluster Disk Data tables, it is not possible to change the storage type (`DISK` or `MEMORY`) of a column online. This means, that when you add or drop an index in such a way that the operation would be performed online, and you want the storage type of the column or columns to be changed, you must use `ALGORITHM=COPY` in the statement that adds or drops the index.

Columns to be added online cannot use the `BLOB` or `TEXT` type, and must meet the following criteria:

- The columns must be dynamic; that is, it must be possible to create them using `COLUMN_FORMAT DYNAMIC`. If you omit the `COLUMN_FORMAT DYNAMIC` option, the dynamic column format is employed automatically.
- The columns must permit `NULL` values and not have any explicit default value other than `NULL`. Columns added online are automatically created as `DEFAULT NULL`, as can be seen here:

```
mysql> CREATE TABLE t2 (
 > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
 >) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2
 > ADD COLUMN c2 INT,
 > ADD COLUMN c3 INT,
 > ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW CREATE TABLE t1\G
***** 1. row *****
Table: t1
```

```
Create Table: CREATE TABLE `t2` (
 `c1` int(11) NOT NULL AUTO_INCREMENT,
 `c2` int(11) DEFAULT NULL,
 `c3` int(11) DEFAULT NULL,
 PRIMARY KEY (`c1`)
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

- The columns must be added following any existing columns. If you attempt to add a column online before any existing columns or using the `FIRST` keyword, the statement fails with an error.
- Existing table columns cannot be reordered online.

For online `ALTER TABLE` operations on NDB tables, fixed-format columns are converted to dynamic when they are added online, or when indexes are created or dropped online, as shown here (repeating the `CREATE TABLE` and `ALTER TABLE` statements just shown for the sake of clarity):

```
mysql> CREATE TABLE t2 (
 > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
 >) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2
 > ADD COLUMN c2 INT,
 > ADD COLUMN c3 INT,
 > ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW WARNINGS;
***** 1. row *****
Level: Warning
Code: 1478
Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN
***** 2. row *****
Level: Warning
Code: 1478
Message: Converted FIXED field 'c3' to DYNAMIC to enable online ADD COLUMN
2 rows in set (0.00 sec)
```

Only the column or columns to be added online must be dynamic. Existing columns need not be; this includes the table's primary key, which may also be `FIXED`, as shown here:

```
mysql> CREATE TABLE t3 (
 > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY COLUMN_FORMAT FIXED
 >) ENGINE=NDB;
Query OK, 0 rows affected (2.10 sec)

mysql> ALTER TABLE t3 ADD COLUMN c2 INT, ALGORITHM=INPLACE;
Query OK, 0 rows affected, 1 warning (0.78 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW WARNINGS;
***** 1. row *****
Level: Warning
Code: 1478
Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN
1 row in set (0.00 sec)
```

Columns are not converted from `FIXED` to `DYNAMIC` column format by renaming operations. For more information about `COLUMN_FORMAT`, see [Section 13.1.18, “CREATE TABLE Statement”](#).

The `KEY`, `CONSTRAINT`, and `IGNORE` keywords are supported in `ALTER TABLE` statements using `ALGORITHM=INPLACE`.

Beginning with NDB Cluster 7.5.7 and 7.6.3, setting `MAX_ROWS` to 0 using an online `ALTER TABLE` statement is disallowed. You must use a copying `ALTER TABLE` to perform this operation. (Bug #21960004)

## 21.5.12 Distributed Privileges Using Shared Grant Tables

NDB Cluster supports distribution of MySQL users and privileges across all SQL nodes in an NDB Cluster. This support is not enabled by default; you should follow the procedure outlined in this section in order to do so.

Normally, each MySQL server's user privilege tables in the `mysql` database must use the `MyISAM` storage engine, which means that a user account and its associated privileges created on one SQL node are not available on the cluster's other SQL nodes. An SQL file `ndb_dist_priv.sql` provided with the NDB Cluster distribution can be found in the `share` directory in the MySQL installation directory.

The first step in enabling distributed privileges is to load this script into a MySQL Server that functions as an SQL node (which we refer to after this as the *target* SQL node or MySQL Server). You can do this by executing the following command from the system shell on the target SQL node after changing to its MySQL installation directory (where `options` stands for any additional options needed to connect to this SQL node):

```
shell> mysql options -uroot < share/ndb_dist_priv.sql
```

Importing `ndb_dist_priv.sql` creates a number of stored routines (six stored procedures and one stored function) in the `mysql` database on the target SQL node. After connecting to the SQL node in the `mysql` client (as the MySQL `root` user), you can verify that these were created as shown here:

```
mysql> SELECT ROUTINE_NAME, ROUTINE_SCHEMA, ROUTINE_TYPE
 -> FROM INFORMATION_SCHEMA.ROUTINES
 -> WHERE ROUTINE_NAME LIKE 'mysql_cluster%'
 -> ORDER BY ROUTINE_TYPE;
+-----+-----+-----+
| ROUTINE_NAME | ROUTINE_SCHEMA | ROUTINE_TYPE |
+-----+-----+-----+
| mysql_cluster_privileges_are_distributed | mysql | FUNCTION |
| mysql_cluster_backup_privileges | mysql | PROCEDURE |
| mysql_cluster_move_grant_tables | mysql | PROCEDURE |
| mysql_cluster_move_privileges | mysql | PROCEDURE |
| mysql_cluster_restore_local_privileges | mysql | PROCEDURE |
| mysql_cluster_restore_privileges | mysql | PROCEDURE |
| mysql_cluster_restore_privileges_from_local | mysql | PROCEDURE |
+-----+-----+-----+
7 rows in set (0.01 sec)
```

The stored procedure named `mysql_cluster_move_privileges` creates backup copies of the existing privilege tables, then converts them to NDB.

`mysql_cluster_move_privileges` performs the backup and conversion in two steps. The first step is to call `mysql_cluster_backup_privileges`, which creates two sets of copies in the `mysql` database:

- A set of local copies that use the `MyISAM` storage engine. Their names are generated by adding the suffix `_backup` to the original privilege table names.
- A set of distributed copies that use the `NDBCLUSTER` storage engine. These tables are named by prefixing `ndb_` and appending `_backup` to the names of the original tables.

After the copies are created, `mysql_cluster_move_privileges` invokes `mysql_cluster_move_grant_tables`, which contains the `ALTER TABLE ... ENGINE = NDB` statements that convert the `mysql` system tables to NDB.

Normally, you should not invoke either `mysql_cluster_backup_privileges` or `mysql_cluster_move_grant_tables` manually; these stored procedures are intended only for use by `mysql_cluster_move_privileges`.

Although the original privilege tables are backed up automatically, it is always a good idea to create backups manually of the existing privilege tables on all affected SQL nodes before proceeding. You can do this using `mysqldump` in a manner similar to what is shown here:

```
shell> mysqldump options -uroot \
 mysql user db tables_priv columns_priv procs_priv proxies_priv > backup_file
```

To perform the conversion, you must be connected to the target SQL node using the `mysql` client (again, as the MySQL `root` user). Invoke the stored procedure like this:

```
mysql> CALL mysql.mysql_cluster_move_privileges();
Query OK, 0 rows affected (22.32 sec)
```

Depending on the number of rows in the privilege tables, this procedure may take some time to execute. If some of the privilege tables are empty, you may see one or more `No data - zero rows fetched, selected, or processed` warnings when `mysql_cluster_move_privileges` returns. In such cases, the warnings may be safely ignored. To verify that the conversion was successful, you can use the stored function `mysql_cluster_privileges_are_distributed` as shown here:

```
mysql> SELECT CONCAT(
 -> 'Conversion ',
 -> IF(mysql.mysql_cluster_privileges_are_distributed(), 'succeeded', 'failed'),
 -> '.')
 -> AS Result;
+-----+
| Result |
+-----+
| Conversion succeeded. |
+-----+
1 row in set (0.00 sec)
```

`mysql_cluster_privileges_are_distributed` checks for the existence of the distributed privilege tables and returns `1` if all of the privilege tables are distributed; otherwise, it returns `0`.

You can verify that the backups have been created using a query such as this one:

```
mysql> SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
 -> WHERE TABLE_SCHEMA = 'mysql' AND TABLE_NAME LIKE '%backup'
 -> ORDER BY ENGINE;
+-----+-----+
| TABLE_NAME | ENGINE |
+-----+-----+
| db_backup | MyISAM |
| user_backup | MyISAM |
| columns_priv_backup | MyISAM |
| tables_priv_backup | MyISAM |
| proxies_priv_backup | MyISAM |
| procs_priv_backup | MyISAM |
| ndb_columns_priv_backup | ndbcluster |
| ndb_user_backup | ndbcluster |
| ndb_tables_priv_backup | ndbcluster |
| ndb_proxies_priv_backup | ndbcluster |
| ndb_procs_priv_backup | ndbcluster |
| ndb_db_backup | ndbcluster |
+-----+-----+
12 rows in set (0.00 sec)
```

Once the conversion to distributed privileges has been made, any time a MySQL user account is created, dropped, or has its privileges updated on any SQL node, the changes take effect immediately on all other MySQL servers attached to the cluster. Once privileges are distributed, any new MySQL Servers that connect to the cluster automatically participate in the distribution.

### Note

For clients connected to SQL nodes at the time that `mysql_cluster_move_privileges` is executed, you may need to execute `FLUSH PRIVILEGES` on those SQL nodes, or to disconnect and then reconnect the clients, in order for those clients to be able to see the changes in privileges.

All MySQL user privileges are distributed across all connected MySQL Servers. This includes any privileges associated with views and stored routines, even though distribution of views and stored routines themselves is not currently supported.

In the event that an SQL node becomes disconnected from the cluster while `mysql_cluster_move_privileges` is running, you must drop its privilege tables after reconnecting to the cluster, using a statement such as `DROP TABLE IF EXISTS mysql.user mysql.db mysql.tables_priv mysql.columns_priv mysql.procs_priv`. This causes the SQL node to use the shared privilege tables rather than its own local versions of them. This is not needed when connecting a new SQL node to the cluster for the first time.

In the event of an initial restart of the entire cluster (all data nodes shut down, then started again with `--initial`), the shared privilege tables are lost. If this happens, you can restore them using the original target SQL node either from the backups made by `mysql_cluster_move_privileges` or from a dump file created with `mysqldump`. If you need to use a new MySQL Server to perform the restoration, you should start it with `--skip-grant-tables` when connecting to the cluster for the first time; after this, you can restore the privilege tables locally, then distribute them again using `mysql_cluster_move_privileges`. After restoring and distributing the tables, you should restart this MySQL Server without the `--skip-grant-tables` option.

You can also restore the distributed tables using `ndb_restore --restore-privilege-tables` from a backup made using `START BACKUP` in the `ndb_mgm` client. (The `MyISAM` tables created by `mysql_cluster_move_privileges` are not backed up by the `START BACKUP` command.) `ndb_restore` does not restore the privilege tables by default; the `--restore-privilege-tables` option causes it to do so.

You can restore the SQL node's local privileges using either of two procedures.

`mysql_cluster_restore_privileges` works as follows:

1. If copies of the `mysql.ndb_*_backup` tables are available, attempt to restore the system tables from these.
2. Otherwise, attempt to restore the system tables from the local backups named `*_backup` (without the `ndb_` prefix).

The other procedure, named `mysql_cluster_restore_local_privileges`, restores the system tables from the local backups only, without checking the `ndb_*` backups.

The system tables re-created by `mysql_cluster_restore_privileges` or `mysql_cluster_restore_local_privileges` use the MySQL server default storage engine; they are not shared or distributed in any way, and do not use NDB Cluster's `NDB` storage engine.

The additional stored procedure `mysql_cluster_restore_privileges_from_local` is intended for the use of `mysql_cluster_restore_privileges` and `mysql_cluster_restore_local_privileges`. It should not be invoked directly.

#### Important

Applications that access NDB Cluster data directly, including NDB API and ClusterJ applications, are not subject to the MySQL privilege system. This means that, once you have distributed the grant tables, they can be freely accessed by such applications, just as they can any other `NDB` tables. In particular, you should keep in mind that *NDB API and ClusterJ applications can read and write user names, host names, password hashes, and any other contents of the distributed grant tables without any restrictions*.

### 21.5.13 NDB API Statistics Counters and Variables

A number of types of statistical counters relating to actions performed by or affecting `Ndb` objects are available. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion

of various operations; and data and events sent and received by `NDBCLUSTER`. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. `mysqld` exposes these counters as system status variables; their values can be read in the output of `SHOW STATUS`, or by querying the `INFORMATION_SCHEMA.SESSION_STATUS` or `INFORMATION_SCHEMA.GLOBAL_STATUS` table. By comparing the values before and after statements operating on NDB tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following `SHOW STATUS` statement:

```
mysql> SHOW STATUS LIKE 'ndb_api%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 0
| Ndb_api_wait_scan_result_count_session | 0
| Ndb_api_wait_meta_request_count_session | 0
| Ndb_api_wait_nanos_count_session | 0
| Ndb_api_bytes_sent_count_session | 0
| Ndb_api_bytes_received_count_session | 0
| Ndb_api_trans_start_count_session | 0
| Ndb_api_trans_commit_count_session | 0
| Ndb_api_trans_abort_count_session | 0
| Ndb_api_trans_close_count_session | 0
| Ndb_api_pk_op_count_session | 0
| Ndb_api_uk_op_count_session | 0
| Ndb_api_table_scan_count_session | 0
| Ndb_api_range_scan_count_session | 0
| Ndb_api_pruned_scan_count_session | 0
| Ndb_api_scan_batch_count_session | 0
| Ndb_api_read_row_count_session | 0
| Ndb_api_trans_local_read_row_count_session | 0
| Ndb_api_event_data_count_injector | 0
| Ndb_api_event_nondata_count_injector | 0
| Ndb_api_event_bytes_count_injector | 0
| Ndb_api_wait_exec_complete_count_slave | 0
| Ndb_api_wait_scan_result_count_slave | 0
| Ndb_api_wait_meta_request_count_slave | 0
| Ndb_api_wait_nanos_count_slave | 0
| Ndb_api_bytes_sent_count_slave | 0
| Ndb_api_bytes_received_count_slave | 0
| Ndb_api_trans_start_count_slave | 0
| Ndb_api_trans_commit_count_slave | 0
| Ndb_api_trans_abort_count_slave | 0
| Ndb_api_trans_close_count_slave | 0
| Ndb_api_pk_op_count_slave | 0
| Ndb_api_uk_op_count_slave | 0
| Ndb_api_table_scan_count_slave | 0
| Ndb_api_range_scan_count_slave | 0
| Ndb_api_pruned_scan_count_slave | 0
| Ndb_api_scan_batch_count_slave | 0
| Ndb_api_read_row_count_slave | 0
| Ndb_api_trans_local_read_row_count_slave | 0
| Ndb_api_wait_exec_complete_count | 2
| Ndb_api_wait_scan_result_count | 3
| Ndb_api_wait_meta_request_count | 27
| Ndb_api_wait_nanos_count | 45612023
| Ndb_api_bytes_sent_count | 992
| Ndb_api_bytes_received_count | 9640
| Ndb_api_trans_start_count | 2
| Ndb_api_trans_commit_count | 1
| Ndb_api_trans_abort_count | 0
| Ndb_api_trans_close_count | 2
| Ndb_api_pk_op_count | 1
| Ndb_api_uk_op_count | 0
| Ndb_api_table_scan_count | 1
| Ndb_api_range_scan_count | 0
| Ndb_api_pruned_scan_count | 0
| Ndb_api_scan_batch_count | 0
| Ndb_api_read_row_count | 1
| Ndb_api_trans_local_read_row_count | 1
```

## NDB API Statistics Counters and Variables

```
| Ndb_api_event_data_count | 0 |
| Ndb_api_event_nodata_count | 0 |
| Ndb_api_event_bytes_count | 0 |
+-----+-----+
60 rows in set (0.02 sec)
```

These status variables are also available from the `SESSION_STATUS` and `GLOBAL_STATUS` tables of the `INFORMATION_SCHEMA` database, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
-> WHERE VARIABLE_NAME LIKE 'ndb_api%';
+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE |
+-----+-----+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT_SESSION | 2 |
| NDB_API_WAIT_SCAN_RESULT_COUNT_SESSION | 0 |
| NDB_API_WAIT_META_REQUEST_COUNT_SESSION | 1 |
| NDB_API_WAIT_NANOS_COUNT_SESSION | 8144375 |
| NDB_API_BYTES_SENT_COUNT_SESSION | 68 |
| NDB_API_BYTES_RECEIVED_COUNT_SESSION | 84 |
| NDB_API_TRANS_START_COUNT_SESSION | 1 |
| NDB_API_TRANS_COMMIT_COUNT_SESSION | 1 |
| NDB_API_TRANS_ABORT_COUNT_SESSION | 0 |
| NDB_API_TRANS_CLOSE_COUNT_SESSION | 1 |
| NDB_API_PK_OP_COUNT_SESSION | 1 |
| NDB_API_UK_OP_COUNT_SESSION | 0 |
| NDB_API_TABLE_SCAN_COUNT_SESSION | 0 |
| NDB_API_RANGE_SCAN_COUNT_SESSION | 0 |
| NDB_API_PRUNED_SCAN_COUNT_SESSION | 0 |
| NDB_API_SCAN_BATCH_COUNT_SESSION | 0 |
| NDB_API_READ_ROW_COUNT_SESSION | 1 |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT_SESSION | 1 |
| NDB_API_EVENT_DATA_COUNT_INJECTOR | 0 |
| NDB_API_EVENT_NODATA_COUNT_INJECTOR | 0 |
| NDB_API_EVENT_BYTES_COUNT_INJECTOR | 0 |
| NDB_API_WAIT_EXEC_COMPLETE_COUNT_SLAVE | 0 |

| NDB_API_EVENT_NONDATA_COUNT | 0 |
| NDB_API_EVENT_BYTES_COUNT | 0 |
+-----+-----+
60 rows in set (0.00 sec)

```

Each `Ndb` object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multithreaded clients which use more than one `Ndb` object concurrently, it is also possible to obtain a summed view of counters from all `Ndb` objects belonging to a given `Ndb_cluster_connection`.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. *This is in spite of the fact that their values can be obtained as either session or global status variables in the mysql client.* This means that specifying the `SESSION` or `GLOBAL` keyword with `SHOW STATUS` has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the `SESSION_STATUS` or the `GLOBAL_STATUS` table.

- *Session counters (session specific)*

Session counters relate to the `Ndb` objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as “`_session` variables”, with a leading underscore.

- *Replica counters (global)*

This set of counters relates to the `Ndb` objects used by the replicat SQL thread, if any. If this `mysqld` does not act as a replica, or does not use `NDB` tables, then all of these counts are 0.

We refer to the related status variables as “`_slave` variables” (with a leading underscore).

- *Injector counters (global)*

Injector counters relate to the `Ndb` object used to listen to cluster events by the binary log injector thread. Even when not writing a binary log, `mysqld` processes attached to an NDB Cluster continue to listen for some events, such as schema changes.

We refer to the status variables that correspond to NDB API injector counters as “`_injector` variables” (with a leading underscore).

- *Server (Global) counters (global)*

This set of counters relates to all `Ndb` objects currently used by this `mysqld`. This includes all MySQL client applications, the replica SQL thread (if any), the binlog injector, and the `NDB` utility thread.

We refer to the status variables that correspond to these counters as “global variables” or “`mysqld`-level variables”.

You can obtain values for a particular set of variables by additionally filtering for the substring `session`, `slave`, or `injector` in the variable name (along with the common prefix `Ndb_api`). For `_session` variables, this can be done as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%session';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 2 |
| Ndb_api_wait_scan_result_count_session | 0 |
| Ndb_api_wait_meta_request_count_session | 1 |
| Ndb_api_wait_nanos_count_session | 8144375|
| Ndb_api_bytes_sent_count_session | 68 |
| Ndb_api_bytes_received_count_session | 84 |
| Ndb_api_trans_start_count_session | 1 |
| Ndb_api_trans_commit_count_session | 1 |
| Ndb_api_trans_abort_count_session | 0 |
| Ndb_api_trans_close_count_session | 1 |
```

## NDB API Statistics Counters and Variables

```
| Ndb_api_pk_op_count_session | 1 |
| Ndb_api_uk_op_count_session | 0 |
| Ndb_api_table_scan_count_session | 0 |
| Ndb_api_range_scan_count_session | 0 |
| Ndb_api_pruned_scan_count_session | 0 |
| Ndb_api_scan_batch_count_session | 0 |
| Ndb_api_read_row_count_session | 1 |
| Ndb_api_trans_local_read_row_count_session | 1 |
+-----+
18 rows in set (0.50 sec)
```

To obtain a listing of the NDB API `mysqld`-level status variables, filter for variable names beginning with `ndb_api` and ending in `_count`, like this:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
-> WHERE VARIABLE_NAME LIKE 'ndb_api%count';
+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE |
+-----+-----+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT | 4 |
| NDB_API_WAIT_SCAN_RESULT_COUNT | 3 |
| NDB_API_WAIT_META_REQUEST_COUNT | 28 |
| NDB_API_WAIT_NANOS_COUNT | 53756398 |
| NDB_API_BYTES_SENT_COUNT | 1060 |
| NDB_API_BYTES_RECEIVED_COUNT | 9724 |
| NDB_API_TRANS_START_COUNT | 3 |
| NDB_API_TRANS_COMMIT_COUNT | 2 |
| NDB_API_TRANS_ABORT_COUNT | 0 |
| NDB_API_TRANS_CLOSE_COUNT | 3 |
| NDB_API_PK_OP_COUNT | 2 |
| NDB_API_UK_OP_COUNT | 0 |
| NDB_API_TABLE_SCAN_COUNT | 1 |
| NDB_API_RANGE_SCAN_COUNT | 0 |
| NDB_API_PRUNED_SCAN_COUNT | 0 |
| NDB_API_SCAN_BATCH_COUNT | 0 |
| NDB_API_READ_ROW_COUNT | 2 |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT | 2 |
| NDB_API_EVENT_DATA_COUNT | 0 |
| NDB_API_EVENT_NONDATA_COUNT | 0 |
| NDB_API_EVENT_BYTES_COUNT | 0 |
+-----+
21 rows in set (0.09 sec)
```

Not all counters are reflected in all 4 sets of status variables. For the event counters `DataEventsRecvCount`, `NondataEventsRecvCount`, and `EventBytesRecvCount`, only `_injector` and `mysqld`-level NDB API status variables are available:

```
mysql> SHOW STATUS LIKE 'ndb_api%event%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_event_data_count_injector | 0 |
| Ndb_api_event_nodata_count_injector | 0 |
| Ndb_api_event_bytes_count_injector | 0 |
| Ndb_api_event_data_count | 0 |
| Ndb_api_event_nodata_count | 0 |
| Ndb_api_event_bytes_count | 0 |
+-----+
6 rows in set (0.00 sec)
```

`_injector` status variables are not implemented for any other NDB API counters, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%injector%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_event_data_count_injector | 0 |
| Ndb_api_event_nodata_count_injector | 0 |
| Ndb_api_event_bytes_count_injector | 0 |
+-----+
3 rows in set (0.00 sec)
```

The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.

**Table 21.62 NDB API statistics counters**

| Counter Name          | Description                                                                                                                                                                                                                            | Status Variables (by statistic type):                                                                                                                                                                                                   |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       |                                                                                                                                                                                                                                        | <ul style="list-style-type: none"> <li>• <b>Session</b></li> <li>• <b>Slave (replica)</b></li> <li>• <b>Injector</b></li> <li>• <b>Server</b></li> </ul>                                                                                |
| WaitExecCompleteCount | Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all <code>execute()</code> calls as well as implicit executes for blob operations and auto-increment not visible to clients. | <ul style="list-style-type: none"> <li>• <code>Ndb_api_wait_exec_complete_count</code></li> <li>• <code>Ndb_api_wait_exec_complete_count</code></li> <li>• [none]</li> <li>• <code>Ndb_api_wait_exec_complete_count</code></li> </ul>   |
| WaitScanResultCount   | Number of times thread has been blocked while waiting for a scan-based signal, such waiting for additional results, or for a scan to close.                                                                                            | <ul style="list-style-type: none"> <li>• <code>Ndb_api_wait_scan_result_count</code></li> <li>• <code>Ndb_api_wait_scan_result_count</code></li> <li>• [none]</li> <li>• <code>Ndb_api_wait_scan_result_count</code></li> </ul>         |
| WaitMetaRequestCount  | Number of times thread has been blocked waiting for a metadata-based signal; this can occur when waiting for a DDL operation or for an epoch to be started (or ended).                                                                 | <ul style="list-style-type: none"> <li>• <code>Ndb_api_wait_meta_request_count</code></li> <li>• <code>Ndb_api_wait_meta_request_count</code></li> <li>• [none]</li> <li>• <code>Ndb_api_wait_meta_request_count</code></li> </ul>      |
| WaitNanosCount        | Total time (in nanoseconds) spent waiting for some type of signal from the data nodes.                                                                                                                                                 | <ul style="list-style-type: none"> <li>• <code>Ndb_api_wait_nanos_count_session</code></li> <li>• <code>Ndb_api_wait_nanos_count_slave</code></li> <li>• [none]</li> <li>• <code>Ndb_api_wait_nanos_count</code></li> </ul>             |
| BytesSentCount        | Amount of data (in bytes) sent to the data nodes                                                                                                                                                                                       | <ul style="list-style-type: none"> <li>• <code>Ndb_api_bytes_sent_count_session</code></li> <li>• <code>Ndb_api_bytes_sent_count_slave</code></li> <li>• [none]</li> <li>• <code>Ndb_api_bytes_sent_count</code></li> </ul>             |
| BytesRecvCount        | Amount of data (in bytes) received from the data nodes                                                                                                                                                                                 | <ul style="list-style-type: none"> <li>• <code>Ndb_api_bytes_received_count_session</code></li> <li>• <code>Ndb_api_bytes_received_count_slave</code></li> <li>• [none]</li> <li>• <code>Ndb_api_bytes_received_count</code></li> </ul> |
| TransStartCount       | Number of transactions started.                                                                                                                                                                                                        | <ul style="list-style-type: none"> <li>• <code>Ndb_api_trans_start_count_session</code></li> </ul>                                                                                                                                      |

|                                        |                                                                                                                       | <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_range_scan_count_slave</a></li> <li>• [none]</li> <li>• <a href="#">Ndb_api_range_scan_count</a></li> </ul>                                                                                          |
| <a href="#">PrunedScanCount</a>        | Number of scans that have been pruned to a single partition.                                                          | <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_pruned_scan_count_session</a></li> <li>• <a href="#">Ndb_api_pruned_scan_count_slave</a></li> <li>• [none]</li> <li>• <a href="#">Ndb_api_pruned_scan_count</a></li> </ul>                           |
| <a href="#">ScanBatchCount</a>         | Number of batches of rows received. (A <i>batch</i> in this context is a set of scan results from a single fragment.) | <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_scan_batch_count_session</a></li> <li>• <a href="#">Ndb_api_scan_batch_count_slave</a></li> <li>• [none]</li> <li>• <a href="#">Ndb_api_scan_batch_count</a></li> </ul>                              |
| <a href="#">ReadRowCount</a>           | Total number of rows that have been read. Includes rows read using primary key, unique key, and scan operations.      | <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_read_row_count_session</a></li> <li>• <a href="#">Ndb_api_read_row_count_slave</a></li> <li>• [none]</li> <li>• <a href="#">Ndb_api_read_row_count</a></li> </ul>                                    |
| <a href="#">TransLocalReadRowCount</a> | Number of rows read from the data same node on which the transaction was being run.                                   | <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_trans_local_read_row_count</a></li> <li>• <a href="#">Ndb_api_trans_local_read_row_count_slave</a></li> <li>• [none]</li> <li>• <a href="#">Ndb_api_trans_local_read_row_count_inject</a></li> </ul> |
| <a href="#">DataEventsRecvCount</a>    | Number of row change events received.                                                                                 | <ul style="list-style-type: none"> <li>• [none]</li> <li>• [none]</li> <li>• <a href="#">Ndb_api_event_data_count_inject</a></li> <li>• <a href="#">Ndb_api_event_data_count</a></li> </ul>                                                                       |
| <a href="#">NondataEventsRecvCount</a> | Number of events received, other than row change events.                                                              | <ul style="list-style-type: none"> <li>• [none]</li> <li>• [none]</li> <li>• <a href="#">Ndb_api_event_nodata_count_inject</a></li> <li>• <a href="#">Ndb_api_event_nodata_count</a></li> </ul>                                                                   |
| <a href="#">EventBytesRecvCount</a>    | Number of bytes of events received.                                                                                   | <ul style="list-style-type: none"> <li>• [none]</li> <li>• [none]</li> </ul>                                                                                                                                                                                      |

| Counter Name | Description | Status Variables (by statistic type):                                                                                                           |
|--------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
|              |             | <ul style="list-style-type: none"> <li>• Session</li> <li>• Slave (replica)</li> <li>• Injector</li> <li>• Server</li> </ul>                    |
|              |             | <ul style="list-style-type: none"> <li>• <code>Ndb_api_event_bytes_count_in</code></li> <li>• <code>Ndb_api_event_bytes_count</code></li> </ul> |

To see all counts of committed transactions—that is, all `TransCommitCount` counter status variables—you can filter the results of `SHOW STATUS` for the substring `trans_commit_count`, like this:

```
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_trans_commit_count_session | 1 |
| Ndb_api_trans_commit_count_slave | 0 |
| Ndb_api_trans_commit_count | 2 |
+-----+-----+
3 rows in set (0.00 sec)
```

From this you can determine that 1 transaction has been committed in the current `mysql` client session, and 2 transactions have been committed on this `mysqld` since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding `_session` status variables immediately before and after performing the statement. In this example, after getting the initial values from `SHOW STATUS`, we create in the `test` database an `NDB` table, named `t`, that has a single column:

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----+-----+
| Variable_name | value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 2 |
| Ndb_api_wait_scan_result_count_session | 0 |
| Ndb_api_wait_meta_request_count_session | 3 |
| Ndb_api_wait_nanos_count_session | 820705 |
| Ndb_api_bytes_sent_count_session | 132 |
| Ndb_api_bytes_received_count_session | 372 |
| Ndb_api_trans_start_count_session | 1 |
| Ndb_api_trans_commit_count_session | 1 |
| Ndb_api_trans_abort_count_session | 0 |
| Ndb_api_trans_close_count_session | 1 |
| Ndb_api_pk_op_count_session | 1 |
| Ndb_api_uk_op_count_session | 0 |
| Ndb_api_table_scan_count_session | 0 |
| Ndb_api_range_scan_count_session | 0 |
| Ndb_api_pruned_scan_count_session | 0 |
| Ndb_api_scan_batch_count_session | 0 |
| Ndb_api_read_row_count_session | 1 |
| Ndb_api_trans_local_read_row_count_session | 1 |
+-----+-----+
18 rows in set (0.00 sec)

mysql> USE test;
Database changed
mysql> CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
Query OK, 0 rows affected (0.85 sec)
```

Now you can execute a new `SHOW STATUS` statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
```

## NDB API Statistics Counters and Variables

```
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 8 |
| Ndb_api_wait_scan_result_count_session | 0 |
| Ndb_api_wait_meta_request_count_session | 17 |
| Ndb_api_wait_nanos_count_session | 706871709 |
| Ndb_api_bytes_sent_count_session | 2376 |
| Ndb_api_bytes_received_count_session | 3844 |
| Ndb_api_trans_start_count_session | 4 |
| Ndb_api_trans_commit_count_session | 4 |
| Ndb_api_trans_abort_count_session | 0 |
| Ndb_api_trans_close_count_session | 4 |
| Ndb_api_pk_op_count_session | 6 |
| Ndb_api_uk_op_count_session | 0 |
| Ndb_api_table_scan_count_session | 0 |
| Ndb_api_range_scan_count_session | 0 |
| Ndb_api_pruned_scan_count_session | 0 |
| Ndb_api_scan_batch_count_session | 0 |
| Ndb_api_read_row_count_session | 2 |
| Ndb_api_trans_local_read_row_count_session | 1 |
+-----+-----+
18 rows in set (0.00 sec)
```

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into `t`: Insert the row, then run the same `SHOW STATUS` statement used in the previous example, as shown here:

```
mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)

mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 11 |
| Ndb_api_wait_scan_result_count_session | 6 |
| Ndb_api_wait_meta_request_count_session | 20 |
| Ndb_api_wait_nanos_count_session | 707370418 |
| Ndb_api_bytes_sent_count_session | 2724 |
| Ndb_api_bytes_received_count_session | 4116 |
| Ndb_api_trans_start_count_session | 7 |
| Ndb_api_trans_commit_count_session | 6 |
| Ndb_api_trans_abort_count_session | 0 |
| Ndb_api_trans_close_count_session | 7 |
| Ndb_api_pk_op_count_session | 8 |
| Ndb_api_uk_op_count_session | 0 |
| Ndb_api_table_scan_count_session | 1 |
| Ndb_api_range_scan_count_session | 0 |
| Ndb_api_pruned_scan_count_session | 0 |
| Ndb_api_scan_batch_count_session | 0 |
| Ndb_api_read_row_count_session | 3 |
| Ndb_api_trans_local_read_row_count_session | 2 |
+-----+-----+
18 rows in set (0.00 sec)
```

We can make a number of observations from these results:

- Although we created `t` with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the “before” and “after” values of `Ndb_api_pk_op_count_session`, or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the `NDB` storage engine.
- By comparing successive values for `Ndb_api_wait_nanos_count_session`, we can see that the NDB API operations implementing the `CREATE TABLE` statement waited much longer (706871709 - 820705 = 706051004 nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the `INSERT` (707370418 - 706871709 = 498709 ns or roughly .0005 second). The execution times reported for these statements in the `mysql` client correlate roughly with these figures.

On platforms without sufficient (nanosecond) time resolution, small changes in the value of the `WaitNanosCount` NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of `Ndb_api_wait_nanos_count_session`, `Ndb_api_wait_nanos_count_slave`, or `Ndb_api_wait_nanos_count`.

- The `INSERT` statement incremented both the `RowCount` and `TransLocalRowCount` NDB API statistics counters, as reflected by the increased values of `Ndb_api_read_row_count_session` and `Ndb_api_trans_local_read_row_count_session`.

## 21.5.14 ndbinfo: The NDB Cluster Information Database

`ndbinfo` is a database containing information specific to NDB Cluster.

This database contains a number of tables, each providing a different sort of data about NDB Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

`ndbinfo` is included with NDB Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that `ndbinfo` support is active in a given MySQL Server instance using `SHOW PLUGINS`; if `ndbinfo` support is enabled, you should see a row containing `ndbinfo` in the `Name` column and `ACTIVE` in the `Status` column, as shown here (emphasized text):

| Name                       | Status | Type               | Library | License |
|----------------------------|--------|--------------------|---------|---------|
| binlog                     | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| mysql_native_password      | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| sha256_password            | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| MRG_MYISAM                 | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MEMORY                     | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| CSV                        | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MyISAM                     | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| InnoDB                     | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| INNODB_TRX                 | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_LOCKS               | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_LOCK_WAITS          | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP                 | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP_RESET           | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMPMEM              | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMPMEM_RESET        | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP_PER_INDEX       | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP_PER_INDEX_RESET | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_BUFFER_PAGE         | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_BUFFER_PAGE_LRU     | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_BUFFER_POOL_STATS   | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_TEMP_TABLE_INFO     | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_METRICS             | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_FT_DEFAULT_STOPWORD | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_FT_DELETED          | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_FT_BEING_DELETED    | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_FT_CONFIG           | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_FT_INDEX_CACHE      | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_FT_INDEX_TABLE      | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_TABLES          | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_TABLESTATS      | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_INDEXES         | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |

| INNODB_SYS_FOREIGN_COLS    | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_TABLESPACES     | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_DATAFILES       | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_VIRTUAL         | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| PERFORMANCE_SCHEMA         | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |

## ndbinfo: The NDB Cluster Information Database

```
| ndbCluster | ACTIVE | STORAGE ENGINE | NULL | GPL |
| ndbinfo | ACTIVE | STORAGE ENGINE | NULL | GPL |
| ndb_transid_mysql_connection_map | ACTIVE | INFORMATION SCHEMA | NULL | GPL |
| BLACKHOLE | ACTIVE | STORAGE ENGINE | NULL | GPL |
| ARCHIVE | ACTIVE | STORAGE ENGINE | NULL | GPL |
| partition | ACTIVE | STORAGE ENGINE | NULL | GPL |
| ngram | ACTIVE | FTPPARSER | NULL | GPL |
+-----+-----+-----+-----+-----+
46 rows in set (0.00 sec)
```

You can also do this by checking the output of `SHOW ENGINES` for a line including `ndbinfo` in the `Engine` column and `YES` in the `Support` column, as shown here (emphasized text):

```
mysql> SHOW ENGINES\G
***** 1. row *****
 Engine: ndbcluster
 Support: YES
 Comment: Clustered, fault-tolerant tables
Transactions: YES
 XA: NO
 Savepoints: NO
***** 2. row *****

***** 10. row *****
Engine: MEMORY
Support: YES
Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
XA: NO
Savepoints: NO
10 rows in set (0.00 sec)

```

If `ndbinfo` support is enabled, then you can access `ndbinfo` using SQL statements in `mysql` or another MySQL client. For example, you can see `ndbinfo` listed in the output of `SHOW DATABASES`, as shown here (emphasized text):

```

mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| information_schema |
| mysql |
| /ndbinfo |
| performance_schema |
| sys |
+-----+
5 rows in set (0.04 sec)

```

If the `mysqld` process was not started with the `--ndbcluster` option, `ndbinfo` is not available and is not displayed by `SHOW DATABASES`. If `mysqld` was formerly connected to an NDB Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), `ndbinfo` and its tables remain visible, but an attempt to access any tables (other than `blocks` or `config_params`) fails with `Got error 157 'Connection to NDB failed' from NDBINFO`.

With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` “tables” are actually views generated from internal `NDB` tables not normally visible to the MySQL Server.

All `ndbinfo` tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on `ndbinfo` tables; so joining large `ndbinfo` tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a `WHERE` clause.

`ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```

mysql> USE ndbinfo;
Database changed

mysql> SHOW TABLES;
+-----+
| Tables_in_ndbinfo |
+-----+
| arbitrator_validity_detail |
| arbitrator_validity_summary |
| blocks |
| cluster_locks |
| cluster_operations |
| cluster_transactions |
| config_nodes |
+-----+

```

```

| config_params
| config_values
| counters
| cpustat
| cpustat_1sec
| cpustat_20sec
| cpustat_50ms
| dict_obj_info
| dict_obj_types
| disk_write_speed_aggregate
| disk_write_speed_aggregate_node
| disk_write_speed_base
| diskpagebuffer
| error_messages
| locks_per_fragment
| logbuffers
| logspaces
| membership
| memory_per_fragment
| memoryusage
| nodes
| operations_per_fragment
| processes
| resources
| restart_info
| server_locks
| server_operations
| server_transactions
| table_distribution_status
| table_fragments
| table_info
| table_replicas
| tc_time_track_stats
| threadblocks
| threads
| threadstat
| transporters
+-----+
44 rows in set (0.00 sec)

```

In NDB 7.5.0 (and later), all `ndbinfo` tables use the `NDB` storage engine; however, an `ndbinfo` entry still appears in the output of `SHOW ENGINES` and `SHOW PLUGINS` as described previously.

The `config_values` table was added in NDB 7.5.0.

The `cpustat`, `cpustat_50ms`, `cpustat_1sec`, `cpustat_20sec`, and `threads` tables were added in NDB 7.5.2.

The `cluster_locks`, `locks_per_fragment`, and `server_locks` tables were added in NDB 7.5.3.

The `dict_obj_info`, `table_distribution_status`, `table_fragments`, `table_info`, and `table_replicas` tables were added in NDB 7.5.4.

The `config_nodes` and `processes` tables were added in NDB 7.5.7 and NDB 7.6.2.

The `error_messages` table was added in NDB 7.6.4.

You can execute `SELECT` statements against these tables, just as you would normally expect:

```

mysql> SELECT * FROM memoryusage;
+-----+-----+-----+-----+-----+-----+
| node_id | memory_type | used | used_pages | total | total_pages |
+-----+-----+-----+-----+-----+-----+
| 5 | Data memory | 753664 | 23 | 1073741824 | 32768 |
| 5 | Index memory | 163840 | 20 | 1074003968 | 131104 |
| 5 | Long message buffer| 2304 | 9 | 67108864 | 262144 |
| 6 | Data memory | 753664 | 23 | 1073741824 | 32768 |
| 6 | Index memory | 163840 | 20 | 1074003968 | 131104 |
| 6 | Long message buffer| 2304 | 9 | 67108864 | 262144 |
+-----+-----+-----+-----+-----+-----+

```

```
6 rows in set (0.02 sec)
```

More complex queries, such as the two following `SELECT` statements using the `memoryusage` table, are possible:

```
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
 > FROM memoryusage
 > WHERE memory_type = 'Data memory';
+-----+
| Data Memory Used, All Nodes |
+-----+
| 6460 |
+-----+
1 row in set (0.37 sec)

mysql> SELECT SUM(max) as 'Total IndexMemory Available'
 > FROM memoryusage
 > WHERE memory_type = 'Index memory';
+-----+
| Total IndexMemory Available |
+-----+
| 25664 |
+-----+
1 row in set (0.33 sec)
```

`ndbinfo` table and column names are case-sensitive (as is the name of the `ndbinfo` database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```
mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+
| node_id | uptime | status | start_phase |
+-----+-----+-----+-----+
| 1 | 13602 | STARTED | 0 |
| 2 | 16 | STARTED | 0 |
+-----+-----+-----+-----+
2 rows in set (0.04 sec)

mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): Table 'ndbinfo.Nodes' doesn't exist
```

`mysqldump` ignores the `ndbinfo` database entirely, and excludes it from any output. This is true even when using the `--databases` or `--all-databases` option.

NDB Cluster also maintains tables in the `INFORMATION_SCHEMA` information database, including the `FILES` table which contains information about files used for NDB Cluster Disk Data storage, and the `ndb_transid_mysql_connection_map` table, which shows the relationships between transactions, transaction coordinators, and NDB Cluster API nodes. For more information, see the descriptions of the tables or [Section 21.5.15, “INFORMATION\\_SCHEMA Tables for NDB Cluster”](#).

#### 21.5.14.1 The `ndbinfo arbitrator_validity_detail` Table

The `arbitrator_validity_detail` table shows the view that each data node in the cluster has of the arbitrator. It is a subset of the `membership` table.

The `arbitrator_validity_detail` table contains the following columns:

- `node_id`

This node's node ID

- `arbitrator`

Node ID of arbitrator

- `arb_ticket`

Internal identifier used to track arbitration

- `arb_connected`

Whether this node is connected to the arbitrator; either of `Yes` or `No`

- `arb_state`

Arbitration state

## Notes

The node ID is the same as that reported by `ndb_mgm -e "SHOW"`.

All nodes should show the same `arbitrator` and `arb_ticket` values as well as the same `arb_state` value. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether the current node is connected to the `arbitrator`.

### 21.5.14.2 The `ndbinfo arbitrator_validity_summary` Table

The `arbitrator_validity_summary` table provides a composite view of the arbitrator with regard to the cluster's data nodes.

The `arbitrator_validity_summary` table contains the following columns:

- `arbitrator`

Node ID of arbitrator

- `arb_ticket`

Internal identifier used to track arbitration

- `arb_connected`

Whether this arbitrator is connected to the cluster; either of `Yes` or `No`

- `consensus_count`

Number of data nodes that see this node as arbitrator

## Notes

In normal operations, this table should have only 1 row for any appreciable length of time. If it has more than 1 row for longer than a few moments, then either not all nodes are connected to the arbitrator, or all nodes are connected, but do not agree on the same arbitrator.

The `arbitrator` column shows the arbitrator's node ID.

`arb_ticket` is the internal identifier used by this arbitrator.

`arb_connected` shows whether this node is connected to the cluster as an arbitrator.

### 21.5.14.3 The `ndbinfo blocks` Table

The `blocks` table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see [NDB Kernel Blocks](#)). It is for use by the other `ndbinfo` tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The `blocks` table contains the following columns:

- `block_number`

Block number

- `block_name`

Block name

## Notes

To obtain a list of all block names, simply execute `SELECT block_name FROM ndbinfo.blocks`. Although this is a static table, its content can vary between different NDB Cluster releases.

### 21.5.14.4 The `ndbinfo cluster_locks` Table

The `cluster_locks` table provides information about current lock requests holding and waiting for locks on `NDB` tables in an NDB Cluster, and is intended as a companion table to `cluster_operations`. Information obtain from the `cluster_locks` table may be useful in investigating stalls and deadlocks.

The `cluster_locks` table contains the following columns:

- `node_id`

ID of reporting node

- `block_instance`

ID of reporting LDM instance

- `tableid`

ID of table containing this row

- `fragmentid`

ID of fragment containing locked row

- `rowid`

ID of locked row

- `transid`

Transaction ID

- `mode`

Lock request mode

- `state`

Lock state

- `detail`

Whether this is first holding lock in row lock queue

- `op`

Operation type

- `duration_millis`  
Milliseconds spent waiting or holding lock
- `lock_num`  
ID of lock object
- `waiting_for`  
Waiting for lock with this ID

## Notes

The table ID (`tableid` column) is assigned internally, and is the same as that used in other `ndbinfo` tables. It is also shown in the output of `ndb_show_tables`.

The transaction ID (`transid` column) is the identifier generated by the NDB API for the transaction requesting or holding the current lock.

The `mode` column shows the lock mode; this is always one of `S` (indicating a shared lock) or `X` (an exclusive lock). If a transaction holds an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The `state` column shows the lock state. Its value is always one of `H` (holding) or `W` (waiting). A waiting lock request waits for a lock held by a different transaction.

When the `detail` column contains a `*` (asterisk character), this means that this lock is the first holding lock in the affected row's lock queue; otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The `op` column shows the type of operation requesting the lock. This is always one of the values `READ`, `INSERT`, `UPDATE`, `DELETE`, `SCAN`, or `REFRESH`.

The `duration_millis` column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (`lockid` column) is unique to this node and block instance.

The lock state is shown in the `lock_state` column; if this is `W`, the lock is waiting to be granted, and the `waiting_for` column shows the lock ID of the lock object this request is waiting for. Otherwise, the `waiting_for` column is empty. `waiting_for` can refer only to locks on the same row, as identified by `node_id`, `block_instance`, `tableid`, `fragmentid`, and `rowid`.

The `cluster_locks` table was added in NDB 7.5.3.

## 21.5.14.5 The `ndbinfo cluster_operations` Table

The `cluster_operations` table provides a per-operation (stateful primary key op) view of all activity in the NDB Cluster from the point of view of the local data management (LQH) blocks (see [The DBLQH Block](#)).

The `cluster_operations` table contains the following columns:

- `node_id`  
Node ID of reporting LQH block
- `block_instance`  
LQH block instance
- `transid`

### Transaction ID

- `operation_type`

Operation type (see text for possible values)

- `state`

Operation state (see text for possible values)

- `tableid`

Table ID

- `fragmentid`

Fragment ID

- `client_node_id`

Client node ID

- `client_block_ref`

Client block reference

- `tc_node_id`

Transaction coordinator node ID

- `tc_block_no`

Transaction coordinator block number

- `tc_block_instance`

Transaction coordinator block instance

### Notes

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED RECEIVED COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dblqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an `NDB` table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide, respectively, the `DBLQH` and `DBTC` block instance numbers. You can use these along with the block names to obtain information about specific threads from the `threadblocks` table.

## 21.5.14.6 The ndbinfo cluster\_transactions Table

The `cluster_transactions` table shows information about all ongoing transactions in an NDB Cluster.

The `cluster_transactions` table contains the following columns:

- `node_id`  
Node ID of transaction coordinator
- `block_instance`  
TC block instance
- `transid`  
Transaction ID
- `state`  
Operation state (see text for possible values)
- `count_operations`  
Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations)
- `outstanding_operations`  
Operations still being executed in local data management blocks
- `inactive_seconds`  
Time spent waiting for API
- `client_node_id`  
Client node ID
- `client_block_ref`  
Client block reference

## Notes

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_CONNECTED`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`, `CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb $dbtc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `tc_block_instance` column provides the `DBTC` block instance number. You can use this along with the block name to obtain information about specific threads from the `threadblocks` table.

#### 21.5.14.7 The `ndbinfo config_nodes` Table

The `config_nodes` table shows nodes configured in an NDB Cluster `config.ini` file. For each node, the table displays a row containing the node ID, the type of node (management node, data node, or API node), and the name or IP address of the host on which the node is configured to run.

This table does not indicate whether a given node is actually running, or whether it is currently connected to the cluster. Information about nodes connected to an NDB Cluster can be obtained from the `nodes` and `processes` table.

The `config_nodes` table contains the following columns:

- `node_id`  
The node's ID
- `node_type`  
The type of node
- `node_hostname`  
The name or IP address of the host on which the node resides

#### Notes

The `node_id` column shows the node ID used in the `config.ini` file for this node; if none is specified, the node ID that would be assigned automatically to this node is displayed.

The `node_type` column displays one of the following three values:

- `MGM`: Management node.
- `NDB`: Data node.
- `API`: API node; this includes SQL nodes.

The `node_hostname` column shows the node host as specified in the `config.ini` file. This can be empty for an API node, if `HostName` has not been set in the cluster configuration file. If `HostName` has not been set for a data node in the configuration file, `localhost` is used here. `localhost` is also used if `HostName` has not been specified for a management node.

The `config_nodes` table was added in NDB 7.5.7 and NDB 7.6.2.

#### 21.5.14.8 The `ndbinfo config_params` Table

The `config_params` table is a static table which provides the names and internal ID numbers of and other information about NDB Cluster configuration parameters.

The `config_params` table contains the following columns:

- `param_number`

The parameter's internal ID number

- `param_name`

The name of the parameter

- `param_description`

A brief description of the parameter

- `param_type`

The parameter's data type

- `param_default`

The parameter's default value, if any

- `param_min`

The parameter's maximum value, if any

- `param_max`

The parameter's minimum value, if any

- `param_mandatory`

This is 1 if the parameter is required, otherwise 0

- `param_status`

Currently unused

## Notes

In NDB Cluster 7.5 (and later), this table is read-only. The `param_description`, `param_type`, `param_default`, `param_min`, `param_max`, `param_mandatory`, and `param_status` columns were all added in NDB 7.5.0.

Although this is a static table, its content can vary between NDB Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

### 21.5.14.9 The `ndbinfo config_values` Table

The `config_values` table, implemented in NDB 7.5.0, provides information about the current state of node configuration parameter values. Each row in the table corresponds to the current value of a parameter on a given node.

- `node_id`

ID of the node in the cluster

- `config_param`

The parameter's internal ID number

- [config\\_value](#)

Current value of the parameter

## Notes

This table's [config\\_param](#) column and the [config\\_params](#) table's [param\\_number](#) column use the same parameter identifiers. By joining the two tables on these columns, you can obtain detailed information about desired node configuration parameters. The query shown here provides the current values for all parameters on each data node in the cluster, ordered by node ID and parameter name:

```
SELECT v.node_id AS 'Node Id',
 p.param_name AS 'Parameter',
 v.config_value AS 'Value'
 FROM config_values v
 JOIN config_params p
 ON v.config_param=p.param_number
 WHERE p.param_name NOT LIKE '__%'
 ORDER BY v.node_id, p.param_name;
```

Partial output from the previous query when run on a small example cluster used for simple testing:

| Node Id | Parameter                           | Value          |
|---------|-------------------------------------|----------------|
| 2       | Arbitration                         | 1              |
| 2       | ArbitrationTimeout                  | 7500           |
| 2       | BackupDataBufferSize                | 16777216       |
| 2       | BackupDataDir                       | /home/jon/data |
| 2       | BackupDiskWriteSpeedPct             | 50             |
| 2       | BackupLogBufferSize                 | 16777216       |
| ...     |                                     |                |
| 3       | TotalSendBufferMemory               | 0              |
| 3       | TransactionBufferMemory             | 1048576        |
| 3       | TransactionDeadlockDetectionTimeout | 1200           |
| 3       | TransactionInactiveTimeout          | 4294967039     |
| 3       | TwoPassInitialNodeRestartCopy       | 0              |
| 3       | UndoDataBuffer                      | 16777216       |
| 3       | UndoIndexBuffer                     | 2097152        |

248 rows in set (0.02 sec)

The [WHERE](#) clause filters out parameters whose names begin with a double underscore (\_); these parameters are reserved for testing and other internal uses by the NDB developers, and are not intended for use in a production NDB Cluster.

You can obtain output that is more specific, more detailed, or both by issuing the proper queries. This example provides all types of available information about the [NodeId](#), [NoOfReplicas](#), [HostName](#), [DataMemory](#), [IndexMemory](#), and [TotalSendBufferMemory](#) parameters as currently set for all data nodes in the cluster:

```
SELECT p.param_name AS Name,
 v.node_id AS Node,
 p.param_type AS Type,
 p.param_default AS 'Default',
 p.param_min AS Minimum,
 p.param_max AS Maximum,
 CASE p.param_mandatory WHEN 1 THEN 'Y' ELSE 'N' END AS 'Required',
 v.config_value AS Current
 FROM config_params p
 JOIN config_values v
 ON p.param_number = v.config_param
 WHERE p.param_name
```

```
IN ('NodeId', 'NoOfReplicas', 'HostName',
'DataMemory', 'IndexMemory', 'TotalSendBufferMemory')\G
```

The output from this query when run on a small NDB Cluster with 2 data nodes used for simple testing is shown here:

```
***** 1. row *****
 Name: NodeId

### 21.5.14.10 The `ndbinfo counters` Table

The `counters` table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The `counters` table contains the following columns:

- `node_id`

The data node ID

- `block_name`

Name of the associated NDB kernel block (see [NDB Kernel Blocks](#)).

- `block_instance`

Block instance

- `counter_id`

The counter's internal ID number; normally an integer between 1 and 10, inclusive.

- `counter_name`

The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated.

- `val`

The counter's value

### Notes

Each counter is associated with a particular NDB kernel block.

The `OPERATIONS` counter is associated with the `DBLQH` (local query handler) kernel block (see [The DBLQH Block](#)). A primary-key read counts as one operation, as does a primary-key update. For reads,

there is one operation in [DBLQH](#) per operation in [DBTC](#). For writes, there is one operation counted per fragment replica.

The [ATTRINFO](#), [TRANSACTIONS](#), [COMMITS](#), [READS](#), [LOCAL\\_READS](#), [SIMPLE\\_READS](#), [WRITES](#), [LOCAL\\_WRITES](#), [ABORTS](#), [TABLE\\_SCANS](#), and [RANGE\\_SCANS](#) counters are associated with the DBTC (transaction co-ordinator) kernel block (see [The DBTC Block](#)).

[LOCAL\\_WRITES](#) and [LOCAL\\_READS](#) are primary-key operations using a transaction coordinator in a node that also holds the primary fragment replica of the record.

The [READS](#) counter includes all reads. [LOCAL\\_READS](#) includes only those reads of the primary fragment replica on the same node as this transaction coordinator. [SIMPLE\\_READS](#) includes only those reads in which the read operation is the beginning and ending operation for a given transaction. Simple reads do not hold locks but are part of a transaction, in that they observe uncommitted changes made by the transaction containing them but not of any other uncommitted transactions. Such reads are "simple" from the point of view of the TC block; since they hold no locks they are not durable, and once [DBTC](#) has routed them to the relevant LQH block, it holds no state for them.

[ATTRINFO](#) keeps a count of the number of times an interpreted program is sent to the data node. See [NDB Protocol Messages](#), for more information about [ATTRINFO](#) messages in the [NDB](#) kernel.

The [LOCAL\\_TABLE\\_SCANS\\_SENT](#), [READS\\_RECEIVED](#), [PRUNED\\_RANGE\\_SCANS\\_RECEIVED](#), [RANGE\\_SCANS\\_RECEIVED](#), [LOCAL\\_READS\\_SENT](#), [CONST\\_PRUNED\\_RANGE\\_SCANS\\_RECEIVED](#), [LOCAL\\_RANGE\\_SCANS\\_SENT](#), [REMOTE\\_READS\\_SENT](#), [REMOTE\\_RANGE\\_SCANS\\_SENT](#), [READS\\_NOT\\_FOUND](#), [SCAN\\_BATCHES\\_RETURNED](#), [TABLE\\_SCANS\\_RECEIVED](#), and [SCAN\\_ROWS\\_RETURNED](#) counters are associated with the [DBSPJ](#) (select push-down join) kernel block (see [The DBSPJ Block](#)).

The [block\\_name](#) and [block\\_instance](#) columns provide, respectively, the applicable NDB kernel block name and instance number. You can use these to obtain information about specific threads from the [threadblocks](#) table.

A number of counters provide information about transporter overload and send buffer sizing when troubleshooting such issues. For each LQH instance, there is one instance of each counter in the following list:

- [LQHKEY\\_OVERLOAD](#): Number of primary key requests rejected at the LQH block instance due to transporter overload
- [LQHKEY\\_OVERLOAD\\_TC](#): Count of instances of [LQHKEY\\_OVERLOAD](#) where the TC node transporter was overloaded
- [LQHKEY\\_OVERLOAD\\_READER](#): Count of instances of [LQHKEY\\_OVERLOAD](#) where the API reader (reads only) node was overloaded.
- [LQHKEY\\_OVERLOAD\\_NODE\\_PEER](#): Count of instances of [LQHKEY\\_OVERLOAD](#) where the next backup data node (writes only) was overloaded
- [LQHKEY\\_OVERLOAD\\_SUBSCRIBER](#): Count of instances of [LQHKEY\\_OVERLOAD](#) where a event subscriber (writes only) was overloaded.
- [LQHSCAN\\_SLOWDOWNS](#): Count of instances where a fragment scan batch size was reduced due to scanning API transporter overload.

## 21.5.14.11 The `ndbinfo cpustat` Table

The [cpustat](#) table provides per-thread CPU statistics gathered each second, for each thread running in the [NDB](#) kernel.

The [cpustat](#) table contains the following columns:

- `node_id`  
ID of the node where the thread is running
- `thr_no`  
Thread ID (specific to this node)
- `OS_user`  
OS user time
- `OS_system`  
OS system time
- `OS_idle`  
OS idle time
- `thread_exec`  
Thread execution time
- `thread_sleeping`  
Thread sleep time
- `thread_spinning`  
Thread spin time
- `thread_send`  
Thread send time
- `thread_buffer_full`  
Thread buffer full time
- `elapsed_time`  
Elapsed time

## Notes

This table was added in NDB 7.5.2.

### 21.5.14.12 The `ndbinfo cpustat_50ms` Table

The `cpustat_50ms` table provides raw, per-thread CPU data obtained each 50 milliseconds for each thread running in the `NDB` kernel.

Like `cpustat_1sec` and `cpustat_20sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_50ms` provides 1 second of history.

The `cpustat_50ms` table contains the following columns:

- `node_id`  
ID of the node where the thread is running
- `thr_no`

Thread ID (specific to this node)

- [OS\\_user\\_time](#)  
OS user time
- [OS\\_system\\_time](#)  
OS system time
- [OS\\_idle\\_time](#)  
OS idle time
- [exec\\_time](#)  
Thread execution time
- [sleep\\_time](#)  
Thread sleep time
- [spin\\_time](#)  
Thread spin time
- [send\\_time](#)  
Thread send time
- [buffer\\_full\\_time](#)  
Thread buffer full time
- [elapsed\\_time](#)  
Elapsed time

## Notes

This table was added in NDB 7.5.2.

### 21.5.14.13 The `ndbinfo cpustat_1sec` Table

The `cpustat-1sec` table provides raw, per-thread CPU data obtained each second for each thread running in the NDB kernel.

Like `cpustat_50ms` and `cpustat_20sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_1sec` provides 20 seconds of history.

The `cpustat_1sec` table contains the following columns:

- [node\\_id](#)  
ID of the node where the thread is running
- [thr\\_no](#)  
Thread ID (specific to this node)
- [OS\\_user\\_time](#)  
OS user time

- `OS_system_time`

OS system time

- `OS_idle_time`

OS idle time

- `exec_time`

Thread execution time

- `sleep_time`

Thread sleep time

- `spin_time`

Thread spin time

- `send_time`

Thread send time

- `buffer_full_time`

Thread buffer full time

- `elapsed_time`

Elapsed time

## Notes

This table was added in NDB 7.5.2.

### 21.5.14.14 The `ndbinfo cpustat_20sec` Table

The `cpustat_20sec` table provides raw, per-thread CPU data obtained each 20 seconds, for each thread running in the `NDB` kernel.

Like `cpustat_50ms` and `cpustat_1sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_20sec` provides 400 seconds of history.

The `cpustat_20sec` table contains the following columns:

- `node_id`

ID of the node where the thread is running

- `thr_no`

Thread ID (specific to this node)

- `OS_user_time`

OS user time

- `OS_system_time`

OS system time

- `OS_idle_time`

OS idle time

- `exec_time`

Thread execution time

- `sleep_time`

Thread sleep time

- `spin_time`

Thread spin time

- `send_time`

Thread send time

- `buffer_full_time`

Thread buffer full time

- `elapsed_time`

Elapsed time

## Notes

This table was added in NDB 7.5.2.

### 21.5.14.15 The `ndbinfo dict_obj_info` Table

The `dict_obj_info` table provides information about NDB data dictionary (`DICT`) objects such as tables and indexes. (The `dict_obj_types` table can be queried for a list of all the types.) This information includes the object's type, state, parent object (if any), and fully qualified name.

The `dict_obj_info` table contains the following columns:

- `type`

Type of `DICT` object; join on `dict_obj_types` to obtain the name

- `id`

Object identifier; for Disk Data undo log files and data files, this is the same as the value shown in the `LOGFILE_GROUP_NUMBER` column of the `INFORMATION_SCHEMA.FILES` table

- `version`

Object version

- `state`

Object state

- `parent_obj_type`

Parent object's type (a `dict_obj_types` type ID); 0 indicates that the object has no parent

- `parent_obj_id`

Parent object ID (such as a base table); 0 indicates that the object has no parent

- `fq_name`

Fully qualified object name; for a table, this has the form `database_name/def/table_name`, for a primary key, the form is `sys/def/table_id/PRIMARY`, and for a unique key it is `sys/def/table_id/uk_name$unique`

## Notes

This table was added in NDB 7.5.4.

### 21.5.14.16 The `ndbinfo dict_obj_types` Table

The `dict_obj_types` table is a static table listing possible dictionary object types used in the NDB kernel. These are the same types defined by `Object::Type` in the NDB API.

The `dict_obj_types` table contains the following columns:

- `type_id`

The type ID for this type

- `type_name`

The name of this type

### 21.5.14.17 The `ndbinfo disk_write_speed_base` Table

The `disk_write_speed_base` table provides base information about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_base` table contains the following columns:

- `node_id`

Node ID of this node

- `thr_no`

Thread ID of this LDM thread

- `millis_ago`

Milliseconds since this reporting period ended

- `millis_passed`

Milliseconds elapsed in this reporting period

- `backup_lcp_bytes_written`

Number of bytes written to disk by local checkpoints and backup processes during this period

- `redo_bytes_written`

Number of bytes written to REDO log during this period

- `target_disk_write_speed`

Actual speed of disk writes per LDM thread (base data)

### 21.5.14.18 The `ndbinfo disk_write_speed_aggregate` Table

The `disk_write_speed_aggregate` table provides aggregated information about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_aggregate` table contains the following columns:

- `node_id`  
Node ID of this node
- `thr_no`  
Thread ID of this LDM thread
- `backup_lcp_speed_last_sec`  
Number of bytes written to disk by backup and LCP processes in the last second
- `redo_speed_last_sec`  
Number of bytes written to REDO log in the last second
- `backup_lcp_speed_last_10sec`  
Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds
- `redo_speed_last_10sec`  
Number of bytes written to REDO log per second, averaged over the last 10 seconds
- `std_dev_backup_lcp_speed_last_10sec`  
Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds
- `std_dev_redo_speed_last_10sec`  
Standard deviation in number of bytes written to REDO log per second, averaged over the last 10 seconds
- `backup_lcp_speed_last_60sec`  
Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds
- `redo_speed_last_60sec`  
Number of bytes written to REDO log per second, averaged over the last 10 seconds
- `std_dev_backup_lcp_speed_last_60sec`  
Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds
- `std_dev_redo_speed_last_60sec`  
Standard deviation in number of bytes written to REDO log per second, averaged over the last 60 seconds
- `slowdowns_due_to_io_lag`  
Number of seconds since last node start that disk writes were slowed due to REDO log I/O lag
- `slowdowns_due_to_high_cpu`  
Number of seconds since last node start that disk writes were slowed due to high CPU usage

- `disk_write_speed_set_to_min`

Number of seconds since last node start that disk write speed was set to minimum

- `current_target_disk_write_speed`

Actual speed of disk writes per LDM thread (aggregated)

#### 21.5.14.19 The `ndbinfo disk_write_speed_aggregate_node` Table

The `disk_write_speed_aggregate_node` table provides aggregated information per node about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_aggregate_node` table contains the following columns:

- `node_id`

Node ID of this node

- `backup_lcp_speed_last_sec`

Number of bytes written to disk by backup and LCP processes in the last second

- `redo_speed_last_sec`

Number of bytes written to REDO log in the last second

- `backup_lcp_speed_last_10sec`

Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- `redo_speed_last_10sec`

Number of bytes written to REDO log per second, averaged over the last 10 seconds

- `backup_lcp_speed_last_60sec`

Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- `redo_speed_last_60sec`

Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

#### 21.5.14.20 The `ndbinfo diskpagebuffer` Table

The `diskpagebuffer` table provides statistics about disk page buffer usage by NDB Cluster Disk Data tables.

The `diskpagebuffer` table contains the following columns:

- `node_id`

The data node ID

- `block_instance`

Block instance

- `pages_written`

Number of pages written to disk.

- [pages\\_written\\_lcp](#)

Number of pages written by local checkpoints.

- [pages\\_read](#)

Number of pages read from disk

- [log\\_waits](#)

Number of page writes waiting for log to be written to disk

- [page\\_requests\\_direct\\_return](#)

Number of requests for pages that were available in buffer

- [page\\_requests\\_wait\\_queue](#)

Number of requests that had to wait for pages to become available in buffer

- [page\\_requests\\_wait\\_io](#)

Number of requests that had to be read from pages on disk (pages were unavailable in buffer)

## Notes

You can use this table with NDB Cluster Disk Data tables to determine whether [DiskPageBufferMemory](#) is sufficiently large to allow data to be read from the buffer rather than from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from [DiskPageBufferMemory](#) to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```
SELECT
 node_id,
 100 * page_requests_direct_return /
 (page_requests_direct_return + page_requests_wait_io)
 AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

| node_id | hit_ratio |
|---------|-----------|
| 5       | 97.6744   |
| 6       | 97.6879   |
| 7       | 98.1776   |
| 8       | 98.1343   |

4 rows in set (0.00 sec)

[hit\\_ratio](#) values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for [DiskPageBufferMemory](#) needs to be increased in the [config.ini](#) file.

### Note

A change in [DiskPageBufferMemory](#) requires a rolling restart of all of the cluster's data nodes before it takes effect.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table. Using this information, you can obtain information about disk page buffer metrics relating to individual threads; an example query using `LIMIT 1` to limit the output to a single thread is shown here:

```
mysql> SELECT
 > node_id, thr_no, block_name, thread_name, pages_written,
 > pages_written_lcp, pages_read, log_waits,
 > page_requests_direct_return, page_requests_wait_queue,
 > page_requests_wait_io
 > FROM ndbinfo.diskpagebuffer
 > INNER JOIN ndbinfo.threadblocks USING (node_id, block_instance)
 > INNER JOIN ndbinfo.threads USING (node_id, thr_no)
 > WHERE block_name = 'PGMAN' LIMIT 1\G

1. row ****
 node_id: 1
 thr_no: 1
 block_name: PGMAN
 thread_name: rep
 pages_written: 0
 pages_written_lcp: 0
 pages_read: 1
 log_waits: 0
page_requests_direct_return: 4
 page_requests_wait_queue: 0
 page_requests_wait_io: 1
1 row in set (0.01 sec)
```

### 21.5.14.21 The `ndbinfo error_messages` Table

The `error_messages` table provides information about

The `error_messages` table contains the following columns:

- `error_code`
  - Numeric error code
- `error_description`
  - Description of error
- `error_status`
  - Error status code
- `error_classification`
  - Error classification code

#### Notes

`error_code` is a numeric NDB error code. This is the same error code that can be supplied to `ndb_perror` or `perror --ndb`.

`error_description` provides a basic description of the condition causing the error.

The `error_status` column provides status information relating to the error. Possible values for this column are listed here:

- `No error`
- `Illegal connect string`
- `Illegal server handle`

- `Illegal reply from server`
- `Illegal number of nodes`
- `Illegal node status`
- `Out of memory`
- `Management server not connected`
- `Could not connect to socket`
- `Start failed`
- `Stop failed`
- `Restart failed`
- `Could not start backup`
- `Could not abort backup`
- `Could not enter single user mode`
- `Could not exit single user mode`
- `Failed to complete configuration change`
- `Failed to get configuration`
- `Usage error`
- `Success`
- `Permanent error`
- `Temporary error`
- `Unknown result`
- `Temporary error, restart node`
- `Permanent error, external action needed`
- `Ndbd file system error, restart node initial`
- `Unknown`

The `error_classification` column shows the error classification. See [NDB Error Classifications](#), for information about classification codes and their meanings.

The `error_messages` table was added in NDB 7.6.4.

#### 21.5.14.22 The `ndbinfo locks_per_fragment` Table

The `locks_per_fragment` table provides information about counts of lock claim requests, and the outcomes of these requests on a per-fragment basis, serving as a companion table to `operations_per_fragment` and `memory_per_fragment`. This table also shows the total time spent waiting for locks successfully and unsuccessfully since fragment or table creation, or since the most recent restart.

The `locks_per_fragment` table contains the following columns:

- `fq_name`

Fully qualified table name

- `parent_fq_name`

Fully qualified name of parent object

- `type`

Table type; see text for possible values

- `table_id`

Table ID

- `node_id`

Reporting node ID

- `block_instance`

LDM instance ID

- `fragment_num`

Fragment identifier

- `ex_req`

Exclusive lock requests started

- `ex_imm_ok`

Exclusive lock requests immediately granted

- `ex_wait_ok`

Exclusive lock requests granted following wait

- `ex_wait_fail`

Exclusive lock requests not granted

- `sh_req`

Shared lock requests started

- `sh_imm_ok`

Shared lock requests immediately granted

- `sh_wait_ok`

Shared lock requests granted following wait

- `sh_wait_fail`

Shared lock requests not granted

- `wait_ok_millis`

Time spent waiting for lock requests that were granted, in milliseconds

- `wait_fail_millis`

Time spent waiting for lock requests that failed, in milliseconds

## Notes

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

`fq_name` is a fully qualified database object name in `database/schema/name` format, such as `test/def/t1` or `sys/def/10/b$unique`.

`parent_fq_name` is the fully qualified name of this object's parent object (table).

`table_id` is the table's internal ID generated by NDB. This is the same internal table ID shown in other `ndbinfo` tables; it is also visible in the output of `ndb_show_tables`.

The `type` column shows the type of table. This is always one of `System table`, `User table`, `Unique hash index`, `Hash index`, `Unique ordered index`, `Ordered index`, `Hash index trigger`, `Subscription trigger`, `Read only constraint`, `Index trigger`, `Reorganize trigger`, `Tablespace`, `Log file group`, `Data file`, `Undo file`, `Hash map`, `Foreign key definition`, `Foreign key parent trigger`, `Foreign key child trigger`, or `Schema transaction`.

The values shown in all of the columns `ex_req`, `ex_req_imm_ok`, `ex_wait_ok`, `ex_wait_fail`, `sh_req`, `sh_req_imm_ok`, `sh_wait_ok`, and `sh_wait_fail` represent cumulative numbers of requests since the table or fragment was created, or since the last restart of this node, whichever of these occurred later. This is also true for the time values shown in the `wait_ok_millis` and `wait_fail_millis` columns.

Every lock request is considered either to be in progress, or to have completed in some way (that is, to have succeeded or failed). This means that the following relationships are true:

```
ex_req >= (ex_req_imm_ok + ex_wait_ok + ex_wait_fail)
sh_req >= (sh_req_imm_ok + sh_wait_ok + sh_wait_fail)
```

The number of requests currently in progress is the current number of incomplete requests, which can be found as shown here:

```
[exclusive lock requests in progress] =
 ex_req - (ex_req_imm_ok + ex_wait_ok + ex_wait_fail)

[shared lock requests in progress] =
 sh_req - (sh_req_imm_ok + sh_wait_ok + sh_wait_fail)
```

A failed wait indicates an aborted transaction, but the abort may or may not be caused by a lock wait timeout. You can obtain the total number of aborts while waiting for locks as shown here:

```
[aborts while waiting for locks] = ex_wait_fail + sh_wait_fail
```

The `locks_per_fragment` table was added in NDB 7.5.3.

### 21.5.14.23 The `ndbinfo logbuffers` Table

The `logbuffer` table provides information on NDB Cluster log buffer usage.

The `logbuffers` table contains the following columns:

- `node_id`

The ID of this data node.

- `log_type`

Type of log. Prior to NDB 7.6.6, one of: [REDO](#) or [DD-UNDO](#). In NDB 7.6.6 and later, one of: [REDO](#), [DD-UNDO](#), [BACKUP-DATA](#), or [BACKUP-LOG](#).

- [log\\_id](#)

The log ID; for Disk Data undo log files, this is the same as the value shown in the [LOGFILE\\_GROUP\\_NUMBER](#) column of the [INFORMATION\\_SCHEMA.FILES](#) table as well as the value shown for the [log\\_id](#) column of the [ndbinfo logspaces](#) table

- [log\\_part](#)

The log part number

- [total](#)

Total space available for this log

- [used](#)

Space used by this log

## Notes

Beginning with NDB 7.6.6, [logbuffers](#) table rows reflecting two additional log types are available when performing an NDB backup. One of these rows has the log type [BACKUP-DATA](#), which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type [BACKUP-LOG](#), which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these [log\\_type](#) rows is shown in the [logbuffers](#) table for each data node in the cluster. These rows are not present unless an NDB backup is currently being performed. (Bug #25822988)

### 21.5.14.24 The [ndbinfo logspaces](#) Table

This table provides information about NDB Cluster log space usage.

The [logspaces](#) table contains the following columns:

- [node\\_id](#)

The ID of this data node.

- [log\\_type](#)

Type of log; one of: [REDO](#) or [DD-UNDO](#).

- [log\\_id](#)

The log ID; for Disk Data undo log files, this is the same as the value shown in the [LOGFILE\\_GROUP\\_NUMBER](#) column of the [INFORMATION\\_SCHEMA.FILES](#) table as well as the value shown for the [log\\_id](#) column of the [ndbinfo logbuffers](#) table

- [log\\_part](#)

The log part number.

- [total](#)

Total space available for this log.

- [used](#)

Space used by this log.

## 21.5.14.25 The `ndbinfo membership` Table

The `membership` table describes the view that each data node has of all the others in the cluster, including node group membership, president node, arbitrator, arbitrator successor, arbitrator connection states, and other information.

The `membership` table contains the following columns:

- `node_id`

This node's node ID

- `group_id`

Node group to which this node belongs

- `left_node`

Node ID of the previous node

- `right_node`

Node ID of the next node

- `president`

President's node ID

- `successor`

Node ID of successor to president

- `succession_order`

Order in which this node succeeds to presidency

- `Conf_HB_order`

-

- `arbitrator`

Node ID of arbitrator

- `arb_ticket`

Internal identifier used to track arbitration

- `arb_state`

Arbitration state

- `arb_connected`

Whether this node is connected to the arbitrator; either of `Yes` or `No`

- `connected_rank1_arbs`

Connected arbitrators of rank 1

- `connected_rank2_arbs`

Connected arbitrators of rank 1

## Notes

The node ID and node group ID are the same as reported by `ndb_mgm -e "SHOW"`.

`left_node` and `right_node` are defined in terms of a model that connects all data nodes in a circle, in order of their node IDs, similar to the ordering of the numbers on a clock dial, as shown here:

**Figure 21.39 Circular Arrangement of NDB Cluster Nodes**

In this example, we have 8 data nodes, numbered 5, 6, 7, 8, 12, 13, 14, and 15, ordered clockwise in a circle. We determine “left” and “right” from the interior of the circle. The node to the left of node 5 is node 15, and the node to the right of node 5 is node 6. You can see all these relationships by running the following query and observing the output:

```
mysql> SELECT node_id, left_node, right_node
-> FROM ndbinfo.membership;
+-----+-----+-----+
| node_id | left_node | right_node |
+-----+-----+-----+
| 5 | 15 | 6 |
| 6 | 5 | 7 |
| 7 | 6 | 8 |
| 8 | 7 | 12 |
| 12 | 8 | 13 |
| 13 | 12 | 14 |
| 14 | 13 | 15 |
| 15 | 14 | 5 |
+-----+-----+-----+
8 rows in set (0.00 sec)
```

The designations “left” and “right” are used in the event log in the same way.

The `president` node is the node viewed by the current node as responsible for setting an arbitrator (see [NDB Cluster Start Phases](#)). If the president fails or becomes disconnected, the current node expects the node whose ID is shown in the `successor` column to become the new president. The `succession_order` column shows the place in the succession queue that the current node views itself as having.

In a normal NDB Cluster, all data nodes should see the same node as `president`, and the same node (other than the president) as its `successor`. In addition, the current president should see itself as `1` in the order of succession, the `successor` node should see itself as `2`, and so on.

All nodes should show the same `arb_ticket` values as well as the same `arb_state` values. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether this node is connected to the node shown as this node's `arbitrator`.

The `connected_rank1_arbs` and `connected_rank2_arbs` columns each display a list of 0 or more arbitrators having an `ArbitrationRank` equal to 1, or to 2, respectively.

**Note**

Both management nodes and API nodes are eligible to become arbitrators.

### 21.5.14.26 The `ndbinfo memoryusage` Table

Querying this table provides information similar to that provided by the `ALL REPORT MemoryUsage` command in the `ndb_mgm` client, or logged by `ALL DUMP 1000`.

The `memoryusage` table contains the following columns:

- `node_id`

The node ID of this data node.

- `memory_type`

One of `Data memory`, `Index memory`, or `Long message buffer`.

- `used`

Number of bytes currently used for data memory or index memory by this data node.

- `used_pages`

Number of pages currently used for data memory or index memory by this data node; see text.

- `total`

Total number of bytes of data memory or index memory available for this data node; see text.

- `total_pages`

Total number of memory pages available for data memory or index memory on this data node; see text.

### Notes

The `total` column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the `config.ini` file.

Suppose that the cluster has 2 data nodes having node IDs 5 and 6, and the `config.ini` file contains the following:

```
[ndbd default]
DataMemory = 1G
IndexMemory = 1G
```

Suppose also that the value of the `LongMessageBuffer` configuration parameter is allowed to assume its default (64 MB).

The following query shows approximately the same values:

```
mysql> SELECT node_id, memory_type, total
 > FROM ndbinfo.memoryusage;
+-----+-----+-----+
| node_id | memory_type | total |
+-----+-----+-----+
| 5 | Data memory | 1073741824 |
| 5 | Index memory | 1074003968 |
| 5 | Long message buffer | 67108864 |
| 6 | Data memory | 1073741824 |
| 6 | Index memory | 1074003968 |
| 6 | Long message buffer | 67108864 |
```

```
+-----+-----+-----+
6 rows in set (0.00 sec)
```

In this case, the `total` column values for index memory are slightly higher than the value set of `IndexMemory` due to internal rounding.

For the `used_pages` and `total_pages` columns, resources are measured in pages, which are 32K in size for `DataMemory` and 8K for `IndexMemory`. For long message buffer memory, the page size is 256 bytes.

#### 21.5.14.27 The `ndbinfo memory_per_fragment` Table

The `memory_per_fragment` table provides information about the usage of memory by individual fragments.

The `memory_per_fragment` table contains the following columns:

- `fq_name`  
Name of this fragment
- `parent_fq_name`  
Name of this fragment's parent
- `type`  
Type of object; see text for possible values
- `table_id`  
Table ID for this table
- `node_id`  
Node ID for this node
- `block_instance`  
Kernel block instance ID
- `fragment_num`  
Fragment ID (number)
- `fixed_elem_alloc_bytes`  
Number of bytes allocated for fixed-sized elements
- `fixed_elem_free_bytes`  
Free bytes remaining in pages allocated to fixed-size elements
- `fixed_elem_size_bytes`  
Length of each fixed-size element in bytes
- `fixed_elem_count`  
Number of fixed-size elements
- `fixed_elem_free_count`  
Number of free rows for fixed-size elements

- `var_elem_alloc_bytes`  
Number of bytes allocated for variable-size elements
- `var_elem_free_bytes`  
Free bytes remaining in pages allocated to variable-size elements
- `var_elem_count`  
Number of variable-size elements
- `hash_index_alloc_bytes`  
Number of bytes allocated to hash indexes

## Notes

The `type` column from this table shows the dictionary object type used for this fragment (`Object::Type`, in the NDB API), and can take any one of the values shown in the following list:

- System table
- User table
- Unique hash index
- Hash index
- Unique ordered index
- Ordered index
- Hash index trigger
- Subscription trigger
- Read only constraint
- Index trigger
- Reorganize trigger
- Tablespace
- Log file group
- Data file
- Undo file
- Hash map
- Foreign key definition
- Foreign key parent trigger
- Foreign key child trigger
- Schema transaction

You can also obtain this list by executing `SELECT * FROM ndbinfo.dict_obj_types` in the `mysql` client.

The `block_instance` column provides the NDB kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

### 21.5.14.28 The `ndbinfo nodes` Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The `nodes` table contains the following columns:

- `node_id`

The data node's unique node ID in the cluster.

- `uptime`

Time since the node was last started, in seconds.

- `status`

Current status of the data node; see text for possible values.

- `start_phase`

If the data node is starting, the current start phase.

- `config_generation`

The version of the cluster configuration file in use on this data node.

### Notes

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a `BIGINT` value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmttd` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a nonzero value.

The `status` column shows the node's current status. This is one of: `NOTHING`, `CVMWI`, `STARTING`, `STARTED`, `SINGLEUSER`, `STOPPING_1`, `STOPPING_2`, `STOPPING_3`, or `STOPPING_4`. When the status is `STARTING`, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see [Section 21.5.6, “NDB Cluster Single User Mode”](#)). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state. For example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The `start_phase` column uses the same range of values as those used in the output of the `ndb_mgm` client `node_id STATUS` command (see [Section 21.5.1, “Commands in the NDB Cluster Management Client”](#)). If the node is not currently starting, then this column shows `0`. For a listing of NDB Cluster start phases with descriptions, see [Section 21.5.4, “Summary of NDB Cluster Start Phases”](#).

The `config_generation` column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following `SELECT` statement, you can see that node 3 is not yet using the latest version of the cluster configuration (6) although nodes 1, 2, and 4 are doing so:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+
| node_id | uptime | status | start_phase | config_generation |
+-----+-----+-----+-----+
```

|   | node_id | status  | start_phase | config_generation |
|---|---------|---------|-------------|-------------------|
| 1 | 10462   | STARTED | 0           | 6                 |
| 2 | 10460   | STARTED | 0           | 6                 |
| 3 | 10457   | STARTED | 0           | 5                 |
| 4 | 10455   | STARTED | 0           | 6                 |

2 rows in set (0.04 sec)

Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

Nodes that are stopped are not accounted for in this table. Suppose that you have an NDB Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+
| node_id | uptime | status | start_phase | config_generation |
+-----+-----+-----+-----+
| 1 | 11776 | STARTED | 0 | 6 |
| 2 | 11774 | STARTED | 0 | 6 |
| 3 | 11771 | STARTED | 0 | 6 |
| 4 | 11769 | STARTED | 0 | 6 |
+-----+-----+-----+-----+
4 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this `SELECT` statement, as shown here:

```
ndb_mgm> 2 STOP
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.

mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+
| node_id | uptime | status | start_phase | config_generation |
+-----+-----+-----+-----+
| 1 | 11807 | STARTED | 0 | 6 |
| 3 | 11802 | STARTED | 0 | 6 |
| 4 | 11800 | STARTED | 0 | 6 |
+-----+-----+-----+-----+
3 rows in set (0.02 sec)
```

### 21.5.14.29 The `ndbinfo operations_per_fragment` Table

The `operations_per_fragment` table provides information about the operations performed on individual fragments and fragment replicas, as well as about some of the results from these operations.

The `operations_per_fragment` table contains the following columns:

- `fq_name`
  - Name of this fragment
- `parent_fq_name`
  - Name of this fragment's parent
- `type`
  - Type of object; see text for possible values
- `table_id`
  - Table ID for this table

- `node_id`  
Node ID for this node
- `block_instance`  
Kernel block instance ID
- `fragment_num`  
Fragment ID (number)
- `tot_key_reads`  
Total number of key reads for this fragment replica
- `tot_key_inserts`  
Total number of key inserts for this fragment replica
- `tot_key_updates`  
total number of key updates for this fragment replica
- `tot_key_writes`  
Total number of key writes for this fragment replica
- `tot_key_deletes`  
Total number of key deletes for this fragment replica
- `tot_key_refs`  
Number of key operations refused
- `tot_key_attrinfo_bytes`  
Total size of all `attrinfo` attributes
- `tot_key_keyinfo_bytes`  
Total size of all `keyinfo` attributes
- `tot_key_prog_bytes`  
Total size of all interpreted programs carried by `attrinfo` attributes
- `tot_key_inst_exec`  
Total number of instructions executed by interpreted programs for key operations
- `tot_key_bytes_returned`  
Total size of all data and metadata returned from key read operations
- `tot_frag_scans`  
Total number of scans performed on this fragment replica
- `tot_scan_rows_examined`  
Total number of rows examined by scans
- `tot_scan_rows_returned`

Total number of rows returned to client

- `tot_scan_bytes_returned`

Total size of data and metadata returned to the client

- `tot_scan_prog_bytes`

Total size of interpreted programs for scan operations

- `tot_scan_bound_bytes`

Total size of all bounds used in ordered index scans

- `tot_scan_inst_exec`

Total number of instructions executed for scans

- `tot_qd_frag_scans`

Number of times that scans of this fragment replica have been queued

- `conc_frag_scans`

Number of scans currently active on this fragment replica (excluding queued scans)

- `conc_qd_frag_scans`

Number of scans currently queued for this fragment replica

- `tot_commits`

Total number of row changes committed to this fragment replica

## Notes

The `fq_name` contains the fully qualified name of the schema object to which this fragment replica belongs. This currently has the following formats:

- Base table: `DbName/def/TblName`
- BLOB table: `DbName/def/NDB$BLOB_BaseTblId_ColNo`
- Ordered index: `sys/def/BaseTblId/IndexName`
- Unique index: `sys/def/BaseTblId/IndexName$unique`

The `$unique` suffix shown for unique indexes is added by `mysqld`; for an index created by a different NDB API client application, this may differ, or not be present.

The syntax just shown for fully qualified object names is an internal interface which is subject to change in future releases.

Consider a table `t1` created and modified by the following SQL statements:

```
CREATE DATABASE mydb;

USE mydb;

CREATE TABLE t1 (
 a INT NOT NULL,
 b INT NOT NULL,
 t TEXT NOT NULL,
```

```

PRIMARY KEY (b)
) ENGINE=ndbcluster;

CREATE UNIQUE INDEX ix1 ON t1(b) USING HASH;

```

If `t1` is assigned table ID 11, this yields the `fq_name` values shown here:

- Base table: `mydb/def/t1`
- `BLOB` table: `mydb/def/NDB$BLOB_11_2`
- Ordered index (primary key): `sys/def/11/PRIMARY`
- Unique index: `sys/def/11/ix1$unique`

For indexes or `BLOB` tables, the `parent_fq_name` column contains the `fq_name` of the corresponding base table. For base tables, this column is always `NULL`.

The `type` column shows the schema object type used for this fragment, which can take any one of the values `System table`, `User table`, `Unique hash index`, or `Ordered index`. `BLOB` tables are shown as `User table`.

The `table_id` column value is unique at any given time, but can be reused if the corresponding object has been deleted. The same ID can be seen using the `ndb_show_tables` utility.

The `block_instance` column shows which LDM instance this fragment replica belongs to. You can use this to obtain information about specific threads from the `threadblocks` table. The first such instance is always numbered 0.

Since there are typically two replicas, and assuming that this is so, each `fragment_num` value should appear twice in the table, on two different data nodes from the same node group.

Since `NDB` does not use single-key access for ordered indexes, the counts for `tot_key_reads`, `tot_key_inserts`, `tot_key_updates`, `tot_key_writes`, and `tot_key_deletes` are not incremented by ordered index operations.

#### Note

When using `tot_key_writes`, you should keep in mind that a write operation in this context updates the row if the key exists, and inserts a new row otherwise. (One use of this is in the `NDB` implementation of the `REPLACE` SQL statement.)

The `tot_key_refs` column shows the number of key operations refused by the LDM. Generally, such a refusal is due to duplicate keys (inserts), `Key not found` errors (updates, deletes, and reads), or the operation was rejected by an interpreted program used as a predicate on the row matching the key.

The `attrinfo` and `keyinfo` attributes counted by the `tot_key_attrinfo_bytes` and `tot_key_keyinfo_bytes` columns are attributes of an `LQHKEYREQ` signal (see [The NDB Communication Protocol](#)) used to initiate a key operation by the LDM. An `attrinfo` typically contains tuple field values (inserts and updates) or projection specifications (for reads); `keyinfo` contains the primary or unique key needed to locate a given tuple in this schema object.

The value shown by `tot_frag_scans` includes both full scans (that examine every row) and scans of subsets. Unique indexes and `BLOB` tables are never scanned, so this value, like other scan-related counts, is 0 for fragment replicas of these.

`tot_scan_rows_examined` may display less than the total number of rows in a given fragment replica, since ordered index scans can be limited by bounds. In addition, a client may choose to end a scan before all potentially matching rows have been examined; this occurs when using an SQL statement containing a `LIMIT` or `EXISTS` clause, for example. `tot_scan_rows_returned` is always less than or equal to `tot_scan_rows_examined`.

`tot_scan_bytes_returned` includes, in the case of pushed joins, projections returned to the `DBSPJ` block in the NDB kernel.

`tot_qd_frag_scans` can be effected by the setting for the `MaxParallelScansPerFragment` data node configuration parameter, which limits the number of scans that may execute concurrently on a single fragment replica.

### 21.5.14.30 The `ndbinfo processes` Table

This table contains information about NDB Cluster node processes; each node is represented by the row in the table. Only nodes that are connected to the cluster are shown in this table. You can obtain information about nodes that are configured but not connected to the cluster from the `nodes` and `config_nodes` tables.

The `processes` table contains the following columns:

- `node_id`

The node's unique node ID in the cluster

- `node_type`

Type of node (management, data, or API node; see text)

- `node_version`

Version of the `NDB` software program running on this node.

- `process_id`

This node's process ID

- `angel_process_id`

Process ID of this node's angel process

- `process_name`

Name of the executable

- `service_URI`

Service URI of this node (see text)

#### Notes

`node_id` is the ID assigned to this node in the cluster.

The `node_type` column displays one of the following three values:

- `MGM`: Management node.
- `NDB`: Data node.
- `API`: API or SQL node.

For an executable shipped with the NDB Cluster distribution, `node_version` shows the two-part MySQL NDB Cluster version string, such as `5.7.33-ndb-7.5.23` or `5.7.33-ndb-7.6.19`, that it was compiled with. See [Version strings used in NDB Cluster software](#), for more information.

`process_id` is the node executable's process ID as shown by the host operating system using a process display application such as `top` on Linux, or the Task Manager on Windows platforms.

`angel_process_id` is the system process ID for the node's angel process, which ensures that a data node or SQL is automatically restarted in cases of failures. For management nodes and API nodes other than SQL nodes, the value of this column is `NULL`.

The `process_name` column shows the name of the running executable. For management nodes, this is `ndb_mgmd`. For data nodes, this is `ndbd` (single-threaded) or `ndbmttd` (multithreaded).

For SQL nodes, this is `mysqld`. For other types of API nodes, it is the name of the executable program connected to the cluster; NDB API applications can set a custom value for this using `Ndb_cluster_connection::set_name()`.

`service_URI` shows the service network address. For management nodes and data nodes, the scheme used is `ndb://`. For SQL nodes, this is `mysql://`. By default, API nodes other than SQL nodes use `ndb://` for the scheme; NDB API applications can set this to a custom value using `Ndb_cluster_connection::set_service_uri()`. regardless of the node type, the scheme is followed by the IP address used by the NDB transporter for the node in question. For management nodes and SQL nodes, this address includes the port number (usually 1186 for management nodes and 3306 for SQL nodes). If the SQL node was started with the `bind_address` system variable set, this address is used instead of the transporter address, unless the bind address is set to `*`, `0.0.0.0`, or `::`.

Additional path information may be included in the `service_URI` value for an SQL node reflecting various configuration options. For example, `mysql://198.51.100.3/tmp/mysql.sock` indicates that the SQL node was started with the `skip_networking` system variable enabled, and `mysql://198.51.100.3:3306/?server-id=1` shows that replication is enabled for this SQL node.

The `processes` table was added in NDB 7.5.7 and NDB 7.6.2.

#### 21.5.14.31 The `ndbinfo resources` Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as *super-pools*.

The `resources` table contains the following columns:

- `node_id`

The unique node ID of this data node.

- `resource_name`

Name of the resource; see text.

- `reserved`

The amount reserved for this resource.

- `used`

The amount actually used by this resource.

- `max`

The maximum amount of this resource used, since the node was last started.

#### Notes

The `resource_name` can be any one of the names shown in the following table:

- **RESERVED:** Reserved by the system; cannot be overridden.

- **DISK\_OPERATIONS**: If a log file group is allocated, the size of the undo log buffer is used to set the size of this resource. This resource is used only to allocate the undo log buffer for an undo log file group; there can only be one such group. Overallocation occurs as needed by [CREATE LOGFILE GROUP](#).
- **DISK\_RECORDS**: Records allocated for Disk Data operations.
- **DATA\_MEMORY**: Used for main memory tuples, indexes, and hash indexes. Sum of DataMemory and IndexMemory, plus 8 pages of 32 KB each if IndexMemory has been set. Cannot be overallocated.
- **JOBBUFFER**: Used for allocating job buffers by the NDB scheduler; cannot be overallocated. This is approximately 2 MB per thread plus a 1 MB buffer in both directions for all threads that can communicate. For large configurations this consume several GB.
- **FILE\_BUFFERS**: Used by the redo log handler in the [DBLQH](#) kernel block; cannot be overallocated. Size is [NoOfFragmentLogParts](#) \* [RedoBuffer](#), plus 1 MB per log file part.
- **TRANSPORTER\_BUFFERS**: Used for send buffers by [ndbmtd](#); the sum of [TotalSendBufferMemory](#) and [ExtraSendBufferMemory](#). This resource that can be overallocated by up to 25 percent. [TotalSendBufferMemory](#) is calculated by summing the send buffer memory per node, the default value of which is 2 MB. Thus, in a system having four data nodes and eight API nodes, the data nodes have  $12 * 2$  MB send buffer memory. [ExtraSendBufferMemory](#) is used by [ndbmtd](#) and amounts to 2 MB extra memory per thread. Thus, with 4 LDM threads, 2 TC threads, 1 main thread, 1 replication thread, and 2 receive threads, [ExtraSendBufferMemory](#) is  $10 * 2$  MB. Overallocation of this resource can be performed by setting the [SharedGlobalMemory](#) data node configuration parameter.
- **DISK\_PAGE\_BUFFER**: Used for the disk page buffer; determined by the [DiskPageBufferMemory](#) configuration parameter. Cannot be overallocated.
- **QUERY\_MEMORY**: Used by the [DBSPJ](#) kernel block.
- **SCHEMA\_TRANS\_MEMORY**: Minimum is 2 MB; can be overallocated to use any remaining available memory.

#### 21.5.14.32 The `ndbinfo restart_info` Table

The `restart_info` table contains information about node restart operations. Each entry in the table corresponds to a node restart status report in real time from a data node with the given node ID. Only the most recent report for any given node is shown.

The `restart_info` table contains the following columns:

- **node\_id**  
Node ID in the cluster
- **node\_restart\_status**  
Node status; see text for values. Each of these corresponds to a possible value of `node_restart_status_int`.
- **node\_restart\_status\_int**  
Node status code; see text for values.
- **secs\_to\_complete\_node\_failure**  
Time in seconds to complete node failure handling
- **secs\_to\_allocate\_node\_id**  
Time in seconds from node failure completion to allocation of node ID

- `secs_to_include_in_heartbeat_protocol`  
Time in seconds from allocation of node ID to inclusion in heartbeat protocol
- `secs_until_wait_for_ndbcntr_master`  
Time in seconds from being included in heartbeat protocol until waiting for `NDBCNTR` master began
- `secs_wait_for_ndbcntr_master`  
Time in seconds spent waiting to be accepted by `NDBCNTR` master for starting
- `secs_to_get_start_permitted`  
Time in seconds elapsed from receiving of permission for start from master until all nodes have accepted start of this node
- `secs_to_wait_for_lcp_for_copy_meta_data`  
Time in seconds spent waiting for LCP completion before copying metadata
- `secs_to_copy_meta_data`  
Time in seconds required to copy metadata from master to newly starting node
- `secs_to_include_node`  
Time in seconds waited for GCP and inclusion of all nodes into protocols
- `secs_starting_node_to_request_local_recovery`  
Time in seconds that the node just starting spent waiting to request local recovery
- `secs_for_local_recovery`  
Time in seconds required for local recovery by node just starting
- `secs_restore_fragments`  
Time in seconds required to restore fragments from LCP files
- `secs_undo_disk_data`  
Time in seconds required to execute undo log on disk data part of records
- `secs_exec_redo_log`  
Time in seconds required to execute redo log on all restored fragments
- `secs_index_rebuild`  
Time in seconds required to rebuild indexes on restored fragments
- `secs_to_synchronize_starting_node`  
Time in seconds required to synchronize starting node from live nodes
- `secs_wait_lcp_for_restart`  
Time in seconds required for LCP start and completion before restart was completed
- `secs_wait_subscription_handover`  
Time in seconds spent waiting for handover of replication subscriptions

- `total_restart_secs`

Total number of seconds from node failure until node is started again

## Notes

The following list contains values defined for the `node_restart_status_int` column with their internal status names (in parentheses), and the corresponding messages shown in the `node_restart_status` column:

- 0 (`ALLOCATED_NODE_ID`)  
Allocated node id
- 1 (`INCLUDED_IN_HB_PROTOCOL`)  
Included in heartbeat protocol
- 2 (`NDCNTR_START_WAIT`)  
Wait for NDCNTR master to permit us to start
- 3 (`NDCNTR_STARTED`)  
NDCNTR master permitted us to start
- 4 (`START_PERMITTED`)  
All nodes permitted us to start
- 5 (`WAIT_LCP_TO_COPY_DICT`)  
Wait for LCP completion to start copying metadata
- 6 (`COPY_DICT_TO_STARTING_NODE`)  
Copying metadata to starting node
- 7 (`INCLUDE_NODE_IN_LCP_AND_GCP`)  
Include node in LCP and GCP protocols
- 8 (`LOCAL_RECOVERY_STARTED`)  
Restore fragments ongoing
- 9 (`COPY_FRGMENTS_STARTED`)  
Synchronizing starting node with live nodes
- 10 (`WAIT_LCP_FOR_RESTART`)  
Wait for LCP to ensure durability
- 11 (`WAIT_SUMA_HANDOVER`)  
Wait for handover of subscriptions
- 12 (`RESTART_COMPLETED`)  
Restart completed
- 13 (`NODE_FAILED`)

- Node failed, failure handling in progress
  - 14 (`NODE_FAILURE_COMPLETED`)  
Node failure handling completed
  - 15 (`NODE_GETTING_PERMIT`)  
All nodes permitted us to start
  - 16 (`NODE_GETTING_INCLUDED`)  
Include node in LCP and GCP protocols
  - 17 (`NODE_GETTING_SYNCHED`)  
Synchronizing starting node with live nodes
  - 18 (`NODE_GETTING_LCP_WAITED`)  
[none]
  - 19 (`NODE_ACTIVE`)  
Restart completed
  - 20 (`NOT_DEFINED_IN_CLUSTER`)  
[none]
  - 21 (`NODE_NOT_RESTARTED_YET`)  
Initial state

Status numbers 0 through 12 apply on master nodes only; the remainder of those shown in the table apply to all restarting data nodes. Status numbers 13 and 14 define node failure states; 20 and 21 occur when no information about the restart of a given node is available.

See also [Section 21.5.4, “Summary of NDB Cluster Start Phases”](#).

#### 21.5.14.33 The `ndbinfo server_locks` Table

The `server_locks` table is similar in structure to the `cluster_locks` table, and provides a subset of the information found in the latter table, but which is specific to the SQL node (MySQL server) where it resides. (The `cluster_locks` table provides information about all locks in the cluster.) More precisely, `server_locks` contains information about locks requested by threads belonging to the current `mysqld` instance, and serves as a companion table to `server_operations`. This may be useful for correlating locking patterns with specific MySQL user sessions, queries, or use cases.

The `server_locks` table contains the following columns:

- `mysql_connection_id`  
MySQL connection ID
- `node_id`  
ID of reporting node
- `block_instance`  
ID of reporting LDM instance

- `tableid`  
ID of table containing this row
- `fragmentid`  
ID of fragment containing locked row
- `rowid`  
ID of locked row
- `transid`  
Transaction ID
- `mode`  
Lock request mode
- `state`  
Lock state
- `detail`  
Whether this is first holding lock in row lock queue
- `op`  
Operation type
- `duration_millis`  
Milliseconds spent waiting or holding lock
- `lock_num`  
ID of lock object
- `waiting_for`  
Waiting for lock with this ID

## Notes

The `mysql_connection_id` column shows the MySQL connection or thread ID as shown by `SHOW PROCESSLIST`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The `tableid` is assigned to the table by NDB; the same ID is used for this table in other `ndbinfo` tables, as well as in the output of `ndb_show_tables`.

The transaction ID shown in the `transid` column is the identifier generated by the NDB API for the transaction requesting or holding the current lock.

The `mode` column shows the lock mode, which is always one of `S` (shared lock) or `X` (exclusive lock). If a transaction has an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The `state` column shows the lock state. Its value is always one of `H` (holding) or `W` (waiting). A waiting lock request waits for a lock held by a different transaction.

The `detail` column indicates whether this lock is the first holding lock in the affected row's lock queue, in which case it contains a \* (asterisk character); otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The `op` column shows the type of operation requesting the lock. This is always one of the values `READ`, `INSERT`, `UPDATE`, `DELETE`, `SCAN`, or `REFRESH`.

The `duration_millis` column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (`lockid` column) is unique to this node and block instance.

If the `lock_state` column's value is `W`, this lock is waiting to be granted, and the `waiting_for` column shows the lock ID of the lock object this request is waiting for. Otherwise, `waiting_for` is empty. `waiting_for` can refer only to locks on the same row (as identified by `node_id`, `block_instance`, `tableid`, `fragmentid`, and `rowid`).

The `server_locks` table was added in NDB 7.5.3.

#### 21.5.14.34 The `ndbinfo server_operations` Table

The `server_operations` table contains entries for all ongoing NDB operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the `cluster_operations` table, in which operations for other SQL and API nodes are not shown.

The `server_operations` table contains the following columns:

- `mysql_connection_id`

MySQL Server connection ID

- `node_id`

Node ID

- `block_instance`

Block instance

- `transid`

Transaction ID

- `operation_type`

Operation type (see text for possible values)

- `state`

Operation state (see text for possible values)

- `tableid`

Table ID

- `fragmentid`

Fragment ID

- `client_node_id`

Client node ID

- `client_block_ref`  
Client block reference
- `tc_node_id`  
Transaction coordinator node ID
- `tc_block_no`  
Transaction coordinator block number
- `tc_block_instance`  
Transaction coordinator block instance

## Notes

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (`transid`) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED RECEIVED COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$db1qh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide NDB kernel block instance numbers. You can use these to obtain information about specific threads from the `threadblocks` table.

### 21.5.14.35 The `ndbinfo server_transactions` Table

The `server_transactions` table is subset of the `cluster_transactions` table, but includes only those transactions in which the current SQL node (MySQL Server) is a participant, while including the relevant connection IDs.

The `server_transactions` table contains the following columns:

- `mysql_connection_id`  
MySQL Server connection ID
- `node_id`  
Transaction coordinator node ID
- `block_instance`  
Transaction coordinator block instance
- `transid`  
Transaction ID
- `state`  
Operation state (see text for possible values)
- `count_operations`  
Number of stateful operations in the transaction
- `outstanding_operations`  
Operations still being executed by local data management layer (LQH blocks)
- `inactive_seconds`  
Time spent waiting for API
- `client_node_id`  
Client node ID
- `client_block_ref`  
Client block reference

## Notes

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (`transid`) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_CONNECTED`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`, `CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with

`ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dbtc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` column provides the DBTC kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

## 21.5.14.36 The `ndbinfo table_distribution_status` Table

The `table_distribution_status` table provides information about the progress of table distribution for NDB tables.

The `table_distribution_status` table contains the following columns:

- `node_id`

Node id

- `table_id`

Table ID

- `tab_copy_status`

Status of copying of table distribution data to disk; one of `IDLE`, `SR_PHASE1_READ_PAGES`, `SR_PHASE2_READ_TABLE`, `SR_PHASE3_COPY_TABLE`, `REMOVE_NODE`, `LCP_READ_TABLE`, `COPY_TAB_REQ`, `COPY_NODE_STATE`, `ADD_TABLE_MASTER`, `ADD_TABLE_SLAVE`, `INVALIDATE_NODE_LCP`, `ALTER_TABLE`, `COPY_TO_SAVE`, or `GET_TABINFO`

- `tab_update_status`

Status of updating of table distribution data; one of `IDLE`, `LOCAL_CHECKPOINT`, `LOCAL_CHECKPOINT_QUEUED`, `REMOVE_NODE`, `COPY_TAB_REQ`, `ADD_TABLE_MASTER`, `ADD_TABLE_SLAVE`, `INVALIDATE_NODE_LCP`, or `CALLBACK`

- `tab_lcp_status`

Status of table LCP; one of `ACTIVE` (waiting for local checkpoint to be performed), `WRITING_TO_FILE` (checkpoint performed but not yet written to disk), or `COMPLETED` (checkpoint performed and persisted to disk)

- `tab_status`

Table internal status; one of `ACTIVE` (table exists), `CREATING` (table is being created), or `DROPPING` (table is being dropped)

- `tab_storage`

Table recoverability; one of `NORMAL` (fully recoverable with redo logging and checkpointing), `NOLOGGING` (recoverable from node crash, empty following cluster crash), or `TEMPORARY` (not recoverable)

- `tab_partitions`

Number of partitions in table

- `tab_fragments`

Number of fragments in table; normally same as `tab_partitions`; for fully replicated tables equal to `tab_partitions * [number of node groups]`

- `current_scan_count`  
Current number of active scans
- `scan_count_wait`  
Current number of scans waiting to be performed before `ALTER TABLE` can complete.
- `is_reorg_ongoing`  
Whether table is currently being reorganized (1 if true)

## Notes

The `table_distribution_status` table was added in NDB 7.5.4.

### 21.5.14.37 The `ndbinfo table_fragments` Table

The `table_fragments` table provides information about the fragmentation, partitioning, distribution, and (internal) replication of `NDB` tables.

The `table_fragments` table contains the following columns:

- `node_id`  
Node ID (`DIH master`)
- `table_id`  
Table ID
- `partition_id`  
Partition ID
- `fragment_id`  
Fragment ID (same as partition ID unless table is fully replicated)
- `partition_order`  
Order of fragment in partition
- `log_part_id`  
Log part ID of fragment
- `no_of_replicas`  
Number of fragment replicas
- `current_primary`  
Current primary node ID
- `preferred_primary`  
Preferred primary node ID
- `current_first_backup`  
Current first backup node ID
- `current_second_backup`

Current second backup node ID

- `current_third_backup`

Current third backup node ID

- `num_alive_replicas`

Current number of live fragment replicas

- `num_dead_replicas`

Current number of dead fragment replicas

- `num_lcp_replicas`

Number of fragment replicas remaining to be checkpointed

## Notes

The `table_fragments` table was added in NDB 7.5.4.

### 21.5.14.38 The `ndbinfo table_info` Table

The `table_info` table provides information about logging, checkpointing, distribution, and storage options in effect for individual `NDB` tables.

The `table_info` table contains the following columns:

- `table_id`

Table ID

- `logged_table`

Whether table is logged (1) or not (0)

- `row_contains_gci`

Whether table rows contain GCI (1 true, 0 false)

- `row_contains_checksum`

Whether table rows contain checksum (1 true, 0 false)

- `read_backup`

If backup fragment replicas are read this is 1, otherwise 0

- `fully_replicated`

If table is fully replicated this is 1, otherwise 0

- `storage_type`

Table storage type; one of `MEMORY` or `DISK`

- `hashmap_id`

Hashmap ID

- `partition_balance`

Partition balance (fragment count type) used for table; one of `FOR_RP_BY_NODE`, `FOR_RA_BY_NODE`, `FOR_RP_BY_LDM`, or `FOR_RA_BY_LDM`

- `create_gci`

GCI in which table was created

## Notes

The `table_info` table was added in NDB 7.5.4.

### 21.5.14.39 The `ndbinfo table_replicas` Table

The `table_replicas` table provides information about the copying, distribution, and checkpointing of NDB table fragments and fragment replicas.

The `table_replicas` table contains the following columns:

- `node_id`

ID of the node from which data is fetched (`DIH master`)

- `table_id`

Table ID

- `fragment_id`

Fragment ID

- `initial_gci`

Initial GCI for table

- `replica_node_id`

ID of node where fragment replica is stored

- `is_lcp_ongoing`

Is 1 if LCP is ongoing on this fragment, 0 otherwise

- `num_crashed_replicas`

Number of crashed fragment replica instances

- `last_max_gci_started`

Highest GCI started in most recent LCP

- `last_max_gci_completed`

Highest GCI completed in most recent LCP

- `last_lcp_id`

ID of most recent LCP

- `prev_lcp_id`

ID of previous LCP

- `prev_max_gci_started`

Highest GCI started in previous LCP

- `prev_max_gci_completed`

Highest GCI completed in previous LCP

- `last_create_gci`

Last Create GCI of last crashed fragment replica instance

- `last_replica_gci`

Last GCI of last crashed fragment replica instance

- `is_replica_alive`

1 if this fragment replica is alive, 0 otherwise

## Notes

The `table_replicas` table was added in NDB 7.5.4.

### 21.5.14.40 The `ndbinfo tc_time_track_stats` Table

The `tc_time_track_stats` table provides time-tracking information obtained from the `DBTC` block (TC) instances in the data nodes, through API nodes access `NDB`. Each TC instance tracks latencies for a set of activities it undertakes on behalf of API nodes or other data nodes; these activities include transactions, transaction errors, key reads, key writes, unique index operations, failed key operations of any type, scans, failed scans, fragment scans, and failed fragment scans.

A set of counters is maintained for each activity, each counter covering a range of latencies less than or equal to an upper bound. At the conclusion of each activity, its latency is determined and the appropriate counter incremented. `tc_time_track_stats` presents this information as rows, with a row for each instance of the following:

- Data node, using its ID
- TC block instance
- Other communicating data node or API node, using its ID
- Upper bound value

## Notes

Each row contains a value for each activity type. This is the number of times that this activity occurred with a latency within the range specified by the row (that is, where the latency does not exceed the upper bound).

The `tc_time_track_stats` table contains the following columns:

- `node_id`  
Requesting node ID
- `block_number`  
TC block number
- `block_instance`  
TC block instance number

- `comm_node_id`  
Node ID of communicating API or data node
- `upper_bound`  
Upper bound of interval (in microseconds)
- `scans`  
Based on duration of successful scans from opening to closing, tracked against the API or data nodes requesting them.
- `scan_errors`  
Based on duration of failed scans from opening to closing, tracked against the API or data nodes requesting them.
- `scan_fragments`  
Based on duration of successful fragment scans from opening to closing, tracked against the data nodes executing them
- `scan_fragment_errors`  
Based on duration of failed fragment scans from opening to closing, tracked against the data nodes executing them
- `transactions`  
Based on duration of successful transactions from beginning until sending of commit [ACK](#), tracked against the API or data nodes requesting them. Stateless transactions are not included.
- `transaction_errors`  
Based on duration of failing transactions from start to point of failure, tracked against the API or data nodes requesting them.
- `read_key_ops`  
Based on duration of successful primary key reads with locks. Tracked against both the API or data node requesting them and the data node executing them.
- `write_key_ops`  
Based on duration of successful primary key writes, tracked against both the API or data node requesting them and the data node executing them.
- `index_key_ops`  
Based on duration of successful unique index key operations, tracked against both the API or data node requesting them and the data node executing reads of base tables.
- `key_op_errors`  
Based on duration of all unsuccessful key read or write operations, tracked against both the API or data node requesting them and the data node executing them.

The `block_instance` column provides the `DBTC` kernel block instance number. You can use this together with the block name to obtain information about specific threads from the `threadblocks` table.

#### 21.5.14.41 The `ndbinfo threadblocks` Table

The `threadblocks` table associates data nodes, threads, and instances of `NDB` kernel blocks.

The `threadblocks` table contains the following columns:

- `node_id`  
Node ID
- `thr_no`  
Thread ID
- `block_name`  
Block name
- `block_instance`  
Block instance number

## Notes

The value of the `block_name` in this table is one of the values found in the `block_name` column when selecting from the `ndbinfo.blocks` table. Although the list of possible values is static for a given NDB Cluster release, the list may vary between releases.

The `block_instance` column provides the kernel block instance number.

## 21.5.14.42 The `ndbinfo threads` Table

The `threads` table provides information about threads running in the `NDB` kernel.

The `threads` table contains the following columns:

- `node_id`  
ID of the node where the thread is running
- `thr_no`  
Thread ID (specific to this node)
- `thread_name`  
Thread name (type of thread)
- `thread_description`  
Thread (type) description

## Notes

Sample output from a 2-node example cluster, including thread descriptions, is shown here:

| mysql> SELECT * FROM threads; |        |             |                                                                 |
|-------------------------------|--------|-------------|-----------------------------------------------------------------|
| node_id                       | thr_no | thread_name | thread_description                                              |
| 5                             | 0      | main        | main thread, schema and distribution handling                   |
| 5                             | 1      | rep         | rep thread, asynch replication and proxy block handling         |
| 5                             | 2      | ldm         | ldm thread, handling a set of data partitions                   |
| 5                             | 3      | recv        | receive thread, performing receive and polling for new receives |
| 6                             | 0      | main        | main thread, schema and distribution handling                   |
| 6                             | 1      | rep         | rep thread, asynch replication and proxy block handling         |

|   |   |      |                                                                 |
|---|---|------|-----------------------------------------------------------------|
| 6 | 2 | ldm  | ldm thread, handling a set of data partitions                   |
| 6 | 3 | recv | receive thread, performing receive and polling for new receives |

8 rows in set (0.01 sec)

This table was added in NDB 7.5.2.

#### 21.5.14.43 The `ndbinfo threadstat` Table

The `threadstat` table provides a rough snapshot of statistics for threads running in the `NDB` kernel.

The `threadstat` table contains the following columns:

- `node_id`  
Node ID
- `thr_no`  
Thread ID
- `thr_nm`  
Thread name
- `c_loop`  
Number of loops in main loop
- `c_exec`  
Number of signals executed
- `c_wait`  
Number of times waiting for additional input
- `c_l_sent_prioa`  
Number of priority A signals sent to own node
- `c_l_sent_priob`  
Number of priority B signals sent to own node
- `c_r_sent_prioa`  
Number of priority A signals sent to remote node
- `c_r_sent_priob`  
Number of priority B signals sent to remote node
- `os_tid`  
OS thread ID
- `os_now`  
OS time (ms)
- `os_ru_utime`  
OS user CPU time ( $\mu$ s)

- `os_ru_stime`  
OS system CPU time ( $\mu$ s)
- `os_ru_minflt`  
OS page reclaims (soft page faults)
- `os_ru_majflt`  
OS page faults (hard page faults)
- `os_ru_nvcsw`  
OS voluntary context switches
- `os_ru_nivcsw`  
OS involuntary context switches

## Notes

`os_time` uses the system `gettimeofday()` call.

The values of the `os_ru_utime`, `os_ru_stime`, `os_ru_minflt`, `os_ru_majflt`, `os_ru_nvcsw`, and `os_ru_nivcsw` columns are obtained using the system `getrusage()` call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server's Event Scheduler can be employed to automate such monitoring. For more information, see [Section 23.4, “Using the Event Scheduler”](#).

### 21.5.14.44 The `ndbinfo transporters` Table

This table contains information about NDB transporters.

The `transporters` table contains the following columns:

- `node_id`  
This data node's unique node ID in the cluster
- `remote_node_id`  
The remote data node's node ID
- `status`  
Status of the connection
- `remote_address`  
Name or IP address of the remote host
- `bytes_sent`  
Number of bytes sent using this connection
- `bytes_received`  
Number of bytes received using this connection
- `connect_count`

Number of times connection established on this transporter

- [overloaded](#)

1 if this transporter is currently overloaded, otherwise 0

- [overload\\_count](#)

Number of times this transporter has entered overload state since connecting

- [slowdown](#)

1 if this transporter is in slowdown state, otherwise 0

- [slowdown\\_count](#)

Number of times this transporter has entered slowdown state since connecting

## Notes

For each running data node in the cluster, the [transporters](#) table displays a row showing the status of each of that node's connections with all nodes in the cluster, *including itself*. This information is shown in the table's [status](#) column, which can have any one of the following values: [CONNECTING](#), [CONNECTED](#), [DISCONNECTING](#), or [DISCONNECTED](#).

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status [DISCONNECTED](#). Rows where the [node\\_id](#) is that of a data node which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the [ndbinfo.nodes](#) table.

The [remote\\_address](#) is the host name or address for the node whose ID is shown in the [remote\\_node\\_id](#) column. The [bytes\\_sent](#) from this node and [bytes\\_received](#) by this node are the numbers, respectively, of bytes sent and received by the node using this connection since it was established. For nodes whose status is [CONNECTING](#) or [DISCONNECTED](#), these columns always display 0.

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the [SHOW](#) command in the [ndb\\_mgm](#) client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=1 @10.100.10.1 (5.7.33-ndb-7.6.19, Nodegroup: 0, *)
id=2 @10.100.10.2 (5.7.33-ndb-7.6.19, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @10.100.10.10 (5.7.33-ndb-7.6.19)

[mysqld(API)] 2 node(s)
id=20 @10.100.10.20 (5.7.33-ndb-7.6.19)
id=21 @10.100.10.21 (5.7.33-ndb-7.6.19)
```

There are 10 rows in the [transporters](#) table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
-> FROM ndbinfo.transporters;
+-----+-----+-----+
| node_id | remote_node_id | status |
+-----+-----+-----+
| 1 | 1 | DISCONNECTED
| 1 | 2 | CONNECTED
| 1 | 10 | CONNECTED
```

|  |   |  |    |              |
|--|---|--|----|--------------|
|  | 1 |  | 20 | CONNECTED    |
|  | 1 |  | 21 | CONNECTED    |
|  | 2 |  | 1  | CONNECTED    |
|  | 2 |  | 2  | DISCONNECTED |
|  | 2 |  | 10 | CONNECTED    |
|  | 2 |  | 20 | CONNECTED    |
|  | 2 |  | 21 | CONNECTED    |

10 rows in set (0.04 sec)

If you shut down one of the data nodes in this cluster using the command `2 STOP` in the `ndb_mgm` client, then repeat the previous query (again using the `mysql` client), this table now shows only 5 rows—1 row for each connection from the remaining management node to another node, including both itself and the data node that is currently offline—and displays `CONNECTING` for the status of each remaining connection to the data node that is currently offline, as shown here:

|                                                                                |
|--------------------------------------------------------------------------------|
| mysql> SELECT node_id, remote_node_id, status<br>-> FROM ndbinfo.transporters; |
| +-----+-----+-----+                                                            |
| node_id   remote_node_id   status                                              |
| +-----+-----+-----+                                                            |
| 1   1   DISCONNECTED                                                           |
| 1   2   CONNECTING                                                             |
| 1   10   CONNECTED                                                             |
| 1   20   CONNECTED                                                             |
| 1   21   CONNECTED                                                             |
| +-----+-----+-----+                                                            |

5 rows in set (0.02 sec)

The `connect_count`, `overloaded`, `overload_count`, `slowdown`, and `slowdown_count` counters are reset on connection, and retain their values after the remote node disconnects. The `bytes_sent` and `bytes_received` counters are also reset on connection, and so retain their values following disconnection (until the next connection resets them).

The *overload* state referred to by the `overloaded` and `overload_count` columns occurs when this transporter's send buffer contains more than `OverloadLimit` bytes (default is 80% of `SendBufferMemory`, that is,  $0.8 * 2097152 = 1677721$  bytes). When a given transporter is in a state of overload, any new transaction that tries to use this transporter fails with Error 1218 (`Send Buffers overloaded in NDB kernel`). This affects both scans and primary key operations.

The *slowdown* state referenced by the `slowdown` and `slowdown_count` columns of this table occurs when the transporter's send buffer contains more than 60% of the overload limit (equal to  $0.6 * 2097152 = 1258291$  bytes by default). In this state, any new scan using this transporter has its batch size reduced to minimize the load on the transporter.

Common causes of send buffer slowdown or overloading include the following:

- Data size, in particular the quantity of data stored in `TEXT` columns or `BLOB` columns (or both types of columns)
- Having a data node (`ndbd` or `ndbmt`) on the same host as an SQL node that is engaged in binary logging
- Large number of rows per transaction or transaction batch
- Configuration issues such as insufficient `SendBufferMemory`
- Hardware issues such as insufficient RAM or poor network connectivity

See also [Section 21.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#).

## 21.5.15 INFORMATION\_SCHEMA Tables for NDB Cluster

Two `INFORMATION_SCHEMA` tables provide information that is of particular use when managing an NDB Cluster. The `FILES` table provides information about NDB Cluster Disk Data files. The

`ndb_transid_mysql_connection_map` table provides a mapping between transactions, transaction coordinators, and API nodes.

Additional statistical and other data about NDB Cluster transactions, operations, threads, blocks, and other aspects of performance can be obtained from the tables in the `ndbinfo` database. For information about these tables, see [Section 21.5.14, “ndbinfo: The NDB Cluster Information Database”](#).

## 21.5.16 Quick Reference: NDB Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to an NDB Cluster, and in some cases provide information about the cluster itself.

- `SHOW ENGINE NDB STATUS, SHOW ENGINE NDBCLOUD STATUS`

The output of this statement contains information about the server's connection to the cluster, creation and usage of NDB Cluster objects, and binary logging for NDB Cluster replication.

See [Section 13.7.5.15, “SHOW ENGINE Statement”](#), for a usage example and more detailed information.

- `SHOW ENGINES`

This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

See [Section 13.7.5.16, “SHOW ENGINES Statement”](#), for more detailed information.

### Note

This statement does not support a `LIKE` clause. However, you can use `LIKE` to filter queries against the `INFORMATION_SCHEMA.ENGINES` table, as discussed in the next item.

- `SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']`

This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database. Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a `LIKE` clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with `NDB` support and, if so, whether it is enabled:

```
mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
 -> WHERE ENGINE LIKE 'NDB%';
+-----+
| support |
+-----+
| ENABLED |
+-----+
```

See [Section 24.3.7, “The INFORMATION\\_SCHEMA ENGINES Table”](#), for more information.

- `SHOW VARIABLES LIKE 'NDB%'`

This statement provides a list of most server system variables relating to the `NDB` storage engine, and their values, as shown here, using NDB 7.6:

```
mysql> SHOW VARIABLES LIKE 'NDB%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| ndb_allow_copying_alter_table | ON
| ndb_autoincrement_prefetch_sz | 1
| ndb_batch_size | 32768
| ndb_blob_read_batch_bytes | 65536
```

|                                      |                                                                                                                                                                                                                                                                              |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ndb_blob_write_batch_bytes           | 65536                                                                                                                                                                                                                                                                        |
| ndb_cache_check_time                 | 0                                                                                                                                                                                                                                                                            |
| ndb_clear_apply_status               | ON                                                                                                                                                                                                                                                                           |
| ndb_cluster_connection_pool          | 1                                                                                                                                                                                                                                                                            |

See [Section 5.1.7, “Server System Variables”](#), for more information.

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES WHERE VARIABLE_NAME LIKE 'NDB%';`

Although it is deprecated in NDB 7.5 and NDB 7.6, you can use this statement (and others accessing the `INFORMATION_SCHEMA.GLOBAL_VARIABLES` table) if `show_compatibility_56` is enabled. (Querying the `performance_schema.global_variables` table is preferred; see next item.) It is

equivalent to the `SHOW VARIABLES` statement described in the previous item, and provides almost identical output, as shown here:

```
mysql> SET @@global.show_compatibility_56=ON;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
-> WHERE VARIABLE_NAME LIKE 'NDB%';

mysql> SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES WHERE VARIABLE_NAME LIKE 'NDB%';

| ndbinfo_max_bytes                                                             | 0          |
| ndbinfo_max_rows                                                              | 10         |
| ndbinfo_offline                                                               | OFF        |
| ndbinfo_show_hidden                                                           | OFF        |
| ndbinfo_table_prefix                                                          | ndb\$      |
| ndbinfo_version                                                               | 460301     |

Unlike the case with the `SHOW VARIABLES` statement, it is possible to select individual columns. For example:

```
mysql> SELECT VARIABLE_VALUE
 -> FROM performance_schema.global_variables
 -> WHERE VARIABLE_NAME = 'ndb_force_send';
+-----+
| VARIABLE_VALUE |
+-----+
| ON |
+-----+
```

A more useful query is shown here:

```
mysql> SELECT VARIABLE_NAME AS Name, VARIABLE_VALUE AS Value
 > FROM performance_schema.global_variables
 > WHERE VARIABLE_NAME
 > IN ('version', 'ndb_version',
 > 'ndb_version_string', 'ndbinfo_version');

+-----+-----+
| Name | Value |
+-----+-----+
| ndb_version | 460301 |
| ndb_version_string | ndb-7.6.19 |
| ndbinfo_version | 460301 |
| version | 5.7.33-ndb-7.6.19 |
```

|--|--|

See [Section 25.12.13, “Performance Schema System Variable Tables”](#), and [Section 5.1.7, “Server System Variables”](#), for more information.

- `SHOW STATUS LIKE 'NDB%'`

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

| Variable_name                              | Value         |

| Ndb_index_stat_cache_query                                                                                                                                                                                                                                                                                                                      | 0                        |
| Ndb_index_stat_cache_clean                                                                                                                                                                                                                                                                                                                      | 0                        |

If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in the output of this statement contain a zero or an empty string.

See also [Section 13.7.5.35, “SHOW STATUS Statement”](#).

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_STATUS WHERE VARIABLE_NAME LIKE 'NDB%';`

This statement, although deprecated in NDB 7.5 and NDB 7.6, can be used if `show_compatibility_56` is enabled to obtain similar output to the `SHOW STATUS` statement discussed in the previous item; the preferred method is to query the `performance_schema.global_status` table (see next item). Unlike the case with `SHOW STATUS`, it is possible using the `SELECT` to extract values in SQL for use in scripts for monitoring and automation purposes.

See [Section 24.3.10, “The INFORMATION\\_SCHEMA GLOBAL\\_STATUS and SESSION\\_STATUS Tables](#), as well as [Section 25.20, “Migrating to Performance Schema System and Status Variable Tables”](#), for more information.

- `SELECT * FROM performance_schema.global_status WHERE VARIABLE_NAME LIKE 'NDB%';`

This statement provides similar output to the `SHOW STATUS` statement discussed previously. Unlike the case with `SHOW STATUS`, it is possible using `SELECT` statements to extract values in SQL for use in scripts for monitoring and automation purposes.

See [Section 25.12.14, “Performance Schema Status Variable Tables”](#), for more information.

- `SELECT * FROM INFORMATION_SCHEMA.PLUGINS WHERE PLUGIN_NAME LIKE 'NDB%'`

This statement displays information from the `INFORMATION_SCHEMA.PLUGINS` table about plugins associated with NDB Cluster, such as version, author, and license, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.PLUGINS
 > WHERE PLUGIN_NAME LIKE 'NDB%\G

*** 1. row *****

```

LOAD\_OPTION: ON

You can also use the `SHOW PLUGINS` statement to display this information, but the output from that statement cannot easily be filtered. See also [The MySQL Plugin API](#), which describes where and how the information in the `PLUGINS` table is obtained.

You can also query the tables in the `ndbinfo` information database for real-time data about many NDB Cluster operations. See [Section 21.5.14, “ndbinfo: The NDB Cluster Information Database”](#).

## 21.5.17 NDB Cluster Security Issues

This section discusses security considerations to take into account when setting up and running NDB Cluster.

Topics covered in this section include the following:

- NDB Cluster and network security issues
- Configuration issues relating to running NDB Cluster securely
- NDB Cluster and the MySQL privilege system
- MySQL standard security procedures as applicable to NDB Cluster

### 21.5.17.1 NDB Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to NDB Cluster. It is extremely important to remember that NDB Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster’s efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes effectively slow communications.

It is also true that no authentication is used for controlling API node access to an NDB Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

- SQL or API nodes using “free slots” created by empty `[mysqld]` or `[api]` sections in the `config.ini` file

This means that, if there are any empty `[mysqld]` or `[api]` sections in the `config.ini` file, then any API nodes (including SQL nodes) that know the management server’s host name (or IP address) and port can connect to the cluster and access its data without restriction. (See [Section 21.5.17.2, “NDB Cluster and MySQL Privileges”](#), for more information about this and related issues.)

#### Note

You can exercise some control over SQL and API node access to the cluster by specifying a `HostName` parameter for all `[mysqld]` and `[api]` sections in the `config.ini` file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an `[api]` section containing its host name to the `config.ini` file.

More information is available [elsewhere in this chapter](#) about the `HostName` parameter. Also see [Section 21.3.1, “Quick Test Setup of NDB Cluster”](#), for configuration examples using `HostName` with API nodes.

- Any `ndb_mgm` client

This means that any cluster management client that is given the management server's host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as `ALL STOP` and `SHUTDOWN`.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

We show an example of an NDB Cluster setup using such a physically segregated network here:

**Figure 21.40 NDB Cluster with Hardware Firewall**

This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a *network-based firewall*.

This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network—and none of the cluster's internal communications can reach the outside—without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

### Important

With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See [Section 6.1.3, “Making MySQL Secure Against Attackers”](#), for a description of techniques you can use to secure MySQL servers.

2. Using one or more software firewalls (also known as *host-based firewalls*) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for NDB Cluster is illustrated here:

**Figure 21.41 NDB Cluster with Software Firewalls**

Using this type of network setup means that there are two zones of NDB Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

**Table 21.63 Node types in a host-based firewall cluster configuration**

| Node Type                    | Permitted Traffic                                                                                                                                                                                                                                                            |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQL or API node              | <ul style="list-style-type: none"> <li>It originates from the IP address of a management or data node (using any TCP or UDP port).</li> <li>It originates from within the network in which the cluster resides and is on the port that your application is using.</li> </ul> |
| Data node or Management node | <ul style="list-style-type: none"> <li>It originates from the IP address of a management or data node (using any TCP or UDP port).</li> <li>It originates from the IP address of an SQL or API node.</li> </ul>                                                              |

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. [iptables](#) is a very common and reliable firewall application, which is often used with [APF](#) as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to

implement an NDB Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of an NDB Cluster using hardware and software firewalls in combination is shown here:

**Figure 21.42 NDB Cluster with a Combination of Hardware and Software Firewalls**

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because NDB Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

#### Note

If you wish to administer an NDB Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the cluster's own local network.

Even though it is possible to do so in theory, it is *not* recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

### 21.5.17.2 NDB Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to NDB Cluster and the implications of this for keeping an NDB Cluster secure.

Standard MySQL privileges apply to NDB Cluster tables. This includes all MySQL privilege types (`SELECT` privilege, `UPDATE` privilege, `DELETE` privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on `NDB` tables, databases containing such tables, and columns within such tables are identical in all respects with the `GRANT` and `REVOKE` statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the `CREATE USER` and `DROP USER` statements.

It is important to keep in mind that, by default, the MySQL grant tables use the `MyISAM` storage engine. Because of this, those tables are not normally duplicated or shared among MySQL servers acting as SQL nodes in an NDB Cluster. In other words, changes in users and their privileges do not automatically propagate between SQL nodes by default. If you wish, you can enable automatic distribution of MySQL users and privileges across NDB Cluster SQL nodes; see [Section 21.5.12, “Distributed Privileges Using Shared Grant Tables”](#), for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for `NDB` tables on one SQL node from users that have privileges on another SQL node; (This is true even if you are not using automatic distribution of user privileges. The definitive example of this is the MySQL `root` account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the NDB Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the NDB Cluster.
- There is no firewall, or the firewall fails to protect against access to the NDB Cluster from hosts external to the network.
- The host name or IP address of the NDB Cluster management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with `--ndbcluster --ndb-connectstring=management_host` and access this NDB Cluster. Using the MySQL `root` account, this person can then perform the following actions:

- Execute metadata statements such as `SHOW DATABASES` statement (to obtain a list of all `NDB` databases on the server) or `SHOW TABLES FROM some_ndb_database` statement to obtain a list of all `NDB` tables in a given database
- Run any legal MySQL statements on any of the discovered tables, such as:
  - `SELECT * FROM some_table` to read all the data from any table
  - `DELETE FROM some_table` to delete all the data from a table
  - `DESCRIBE some_table` or `SHOW CREATE TABLE some_table` to determine the table schema
  - `UPDATE some_table SET column1 = some_value` to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

More insidious variations might include statements like these:

```
UPDATE some_table SET an_int_column = an_int_column + 1
```

or

```
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than `NDB`, and so not visible to a “rogue” SQL node.

A user who can log in as `root` can also access the `INFORMATION_SCHEMA` database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in `INFORMATION_SCHEMA`.

It is also a very good idea to use different passwords for the `root` accounts on different NDB Cluster SQL nodes unless you are using distributed privileges.

In sum, you cannot have a safe NDB Cluster if it is directly accessible from outside your local network.

### Important

*Never leave the MySQL root account password empty.* This is just as true when running MySQL as an NDB Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in an NDB Cluster.

If you wish to employ NDB Cluster’s distributed privilege capabilities, you should not simply convert the system tables in the `mysql` database to use the `NDB` storage engine manually. Use the stored procedure provided for this purpose instead; see [Section 21.5.12, “Distributed Privileges Using Shared Grant Tables”](#).

Otherwise, if you need to synchronize `mysql` system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

**Summary.** The most important points to remember regarding the MySQL privilege system with regard to NDB Cluster are listed here:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.
2. You can distribute MySQL users and privileges among SQL nodes using the SQL script, and the stored procedures it contains, that are supplied for this purpose in the NDB Cluster distribution.
3. Once a MySQL user is granted privileges on an `NDB` table from one SQL node in an NDB Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated, even if you are not using privilege distribution.

### 21.5.17.3 NDB Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running NDB Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of an NDB Cluster. First and foremost, you should always run a MySQL Server as the `mysql` operating system user; this is no different from running MySQL in a standard (non-Cluster) environment. The `mysql` system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the `mysql` operating system user by using the system command such as the one shown here:

```
shell> ps aux | grep mysql
```

```

root 10467 0.0 0.1 3616 1380 pts/3 S 11:53 0:00 \
/bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql 10512 0.2 2.5 58528 26636 pts/3 Sl 11:53 0:00 \
/usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql \
--datadir=/usr/local/mysql/var --user=mysql --ndbcluster \
--ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid \
--log-error=/usr/local/mysql/var/mothra.err
jon 10579 0.0 0.0 2736 688 pts/0 S+ 11:54 0:00 grep mysql

```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the `--datadir` option for `mysqld`) is owned by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the MySQL server process with `--user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

### Important

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see [Section 21.5.17.2, “NDB Cluster and MySQL Privileges”](#)), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```

shell> mysql -u root

mysql> UPDATE mysql.user
 -> SET Password=PASSWORD('secure_password')
 -> WHERE User='root';

mysql> DELETE FROM mysql.user
 -> WHERE User='';

mysql> FLUSH PRIVILEGES;

```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting all MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

### Note

Many of the NDB Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See [Section 21.4, “NDB Cluster Programs”](#), for more information about these utilities.

## 21.6 NDB Cluster Replication

NDB Cluster supports *asynchronous replication*, more usually referred to simply as “replication”. This section explains how to set up and manage a configuration in which one group of computers operating as an NDB Cluster replicates to a second computer or group of computers. We assume

some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See [Chapter 16, Replication](#)).

### Note

NDB Cluster does not support replication using GTIDs; semisynchronous replication and group replication are also not supported by the [NDB](#) storage engine.

Normal (non-clustered) replication involves a source server (formerly called a “master”) and a replica server (formerly referred to as a “slave”), the source being so named because operations and data to be replicated originate with it, and the replica being the recipient of these. In NDB Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although an NDB Cluster itself depends on the [NDB](#) storage engine for clustering functionality, it is not necessary to use [NDB](#) as the storage engine for the replica’s copies of the replicated tables (see [Replication from NDB to other storage engines](#)). However, for maximum availability, it is possible (and preferable) to replicate from one NDB Cluster to another, and it is this scenario that we discuss, as shown in the following figure:

**Figure 21.43 NDB Cluster-to-Cluster Replication Layout**

In this scenario, the replication process is one in which successive states of a source cluster are logged and saved to a replica cluster. This process is accomplished by a special thread known as the NDB binary log injector thread, which runs on each MySQL server and produces a binary log ([binlog](#)). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL source and replica servers as replication servers or replication nodes, and the data flow or line of communication between them as a *replication channel*.

For information about performing point-in-time recovery with NDB Cluster and NDB Cluster Replication, see [Section 21.6.9.2, “Point-In-Time Recovery Using NDB Cluster Replication”](#).

**NDB API replica status variables.** NDB API counters can provide enhanced monitoring capabilities on replica clusters. These counters are implemented as NDB statistics [`\_slave`](#) status variables, as

seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in a `mysql` client session connected to a MySQL Server that is acting as a replica in NDB Cluster Replication. By comparing the values of these status variables before and after the execution of statements affecting replicated NDB tables, you can observe the corresponding actions taken on the NDB API level by the replica, which can be useful when monitoring or troubleshooting NDB Cluster Replication. [Section 21.5.13, “NDB API Statistics Counters and Variables”](#), provides additional information.

**Replication from NDB to non-NDB tables.** It is possible to replicate NDB tables from an NDB Cluster acting as the replication source to tables using other MySQL storage engines such as `InnoDB` or `MyISAM` on a replica `mysqld`. This is subject to a number of conditions; see [Replication from NDB to other storage engines](#), and [Replication from NDB to a nontransactional storage engine](#), for more information.

## 21.6.1 NDB Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the source and replica clusters, and to processes and commands run on the clusters or cluster nodes:

**Table 21.64 Abbreviations used throughout this section referring to source and replica clusters, and to processes and commands run on cluster nodes**

| Symbol or Abbreviation   | Description (Refers to...)                                                                         |
|--------------------------|----------------------------------------------------------------------------------------------------|
| <code>S</code>           | The cluster serving as the (primary) replication source                                            |
| <code>R</code>           | The cluster acting as the (primary) replica                                                        |
| <code>shellS&gt;</code>  | Shell command to be issued on the source cluster                                                   |
| <code>mysqlS&gt;</code>  | MySQL client command issued on a single MySQL server running as an SQL node on the source cluster  |
| <code>mysqlS*&gt;</code> | MySQL client command to be issued on all SQL nodes participating in the replication source cluster |
| <code>shellR&gt;</code>  | Shell command to be issued on the replica cluster                                                  |
| <code>mysqlR&gt;</code>  | MySQL client command issued on a single MySQL server running as an SQL node on the replica cluster |
| <code>mysqlR*&gt;</code> | MySQL client command to be issued on all SQL nodes participating in the replica cluster            |
| <code>C</code>           | Primary replication channel                                                                        |
| <code>C'</code>          | Secondary replication channel                                                                      |
| <code>S'</code>          | Secondary replication source                                                                       |
| <code>R'</code>          | Secondary replica                                                                                  |

## 21.6.2 General Requirements for NDB Cluster Replication

A replication channel requires two MySQL servers acting as replication servers (one each for the source and replica). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there should be a total of four replication nodes, two per cluster.

Replication of an NDB Cluster as described in this section and those following is dependent on row-based replication. This means that the replication source MySQL server must be running with `--binlog-format=ROW` or `--binlog-format=MIXED`, as described in [Section 21.6.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”](#). For general information about row-based replication, see [Section 16.2.1, “Replication Formats”](#).

**Important**

If you attempt to use NDB Cluster Replication with `--binlog-format=STATEMENT`, replication fails to work properly because the `ndb_binlog_index` table on the source cluster and the `epoch` column of the `ndb_apply_status` table on the replica cluster are not updated (see [Section 21.6.4, “NDB Cluster Replication Schema and Tables”](#)). Instead, only updates on the MySQL server acting as the replication source propagate to the replica, and no updates from any other SQL nodes in the source cluster are replicated.

The default value for the `--binlog-format` option is `MIXED`.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the source and replica clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where `id` is a unique integer. Although it is not strictly necessary, we assume for purposes of this discussion that all NDB Cluster binaries are of the same release version.

It is generally true in MySQL Replication that both MySQL servers (`mysqld` processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support (see [Section 16.4.2, “Replication Compatibility Between MySQL Versions”](#)). It is due to such differences between the binaries in the NDB Cluster and MySQL Server 5.7 distributions that NDB Cluster Replication has the additional requirement that both `mysqld` binaries come from an NDB Cluster distribution. The simplest and easiest way to assure that the `mysqld` servers are compatible is to use the same NDB Cluster distribution for all source and replica `mysqld` binaries.

We assume that the replica server or cluster is dedicated to replication of the source cluster, and that no other data is being stored on it.

All `NDB` tables being replicated must be created using a MySQL server and client. Tables and other database objects created using the NDB API (with, for example, `Dictionary::createTable()`) are not visible to a MySQL server and so are not replicated. Updates by NDB API applications to existing tables that were created using a MySQL server can be replicated.

**Note**

It is possible to replicate an NDB Cluster using statement-based replication. However, in this case, the following restrictions apply:

- All updates to data rows on the cluster acting as the source must be directed to a single MySQL server.
- It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
- Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see [Section 16.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#), for more specific information concerning the differences between the two replication formats.

## 21.6.3 Known Issues in NDB Cluster Replication

This section discusses known problems or issues when using replication with NDB Cluster.

**Loss of connection between source and replica.** A loss of connection can occur either between the source cluster SQL node and the replica cluster SQL node, or between the source SQL node and the data nodes of the source cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the `MaxBufferedEpochs` and `TimeBetweenEpochs` configuration parameters). If this occurs, *it is entirely possible for new data to be inserted into the source cluster without being recorded in the source SQL node's binary log*. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the replica cluster synchronized with the source. NDB Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

The source SQL node issues a “gap” event when connecting or reconnecting to the source cluster. (A gap event is a type of “incident event,” which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are server failures, database resynchronization, some software updates, and some hardware changes.) When the replica encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See [Section 21.6.8, “Implementing Failover with NDB Cluster Replication”](#), for more information about what to do in such circumstances.

#### Important

Because NDB Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the replica server or cluster, then you must set up multiple replication lines, monitor the source `mysqld` on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see [Section 21.6.7, “Using Two Replication Channels for NDB Cluster Replication”](#), and [Section 21.6.8, “Implementing Failover with NDB Cluster Replication”](#).

If you are replicating from a standalone MySQL server to an NDB Cluster, one channel is usually sufficient.

**Circular replication.** NDB Cluster Replication supports circular replication, as shown in the next example. The replication setup involves three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication source for Cluster 2, Cluster 2 acts as the source for Cluster 3, and Cluster 3 acts as the source for Cluster 1, thus completing the circle. Each NDB Cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all source and replica clusters are the same.
- All SQL nodes acting as sources and replicas are started with the `log_slave_updates` system variable enabled.

This type of circular replication setup is shown in the following diagram:

**Figure 21.44 NDB Cluster Circular Replication With All Sources As Replicas**

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as sources and replicas.

It should also be possible to set up circular replication in which not all source SQL nodes are also replicas, as shown here:

**Figure 21.45 NDB Cluster Circular Replication Where Not All Sources Are Replicas**

In this case, different SQL nodes in each cluster are used as sources and replicas. However, you must *not* start any of the SQL nodes with the `log_slave_updates` system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

#### Note

The NDB storage engine uses *idempotent execution mode*, which suppresses duplicate-key and other errors that otherwise break circular replication of NDB Cluster. This is equivalent to setting the global `slave_exec_mode` system variable to `IDEMPOTENT`, although this is not necessary in NDB Cluster replication, since NDB Cluster sets this variable automatically and ignores any attempts to set it explicitly.

**NDB Cluster replication and primary keys.** In the event of a node failure, errors in replication of NDB tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all NDB tables being replicated have explicit primary keys.

**NDB Cluster Replication and Unique Keys.** In older versions of NDB Cluster, operations that updated values of unique key columns of NDB tables could result in duplicate-key errors when replicated. This issue is solved for replication between NDB tables by deferring unique key checks until after all table row updates have been performed.

Deferring constraints in this way is currently supported only by [NDB](#). Thus, updates of unique keys when replicating from [NDB](#) to a different storage engine such as [InnoDB](#) or [MyISAM](#) are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using [NDB](#) table such as `t`, is created and populated on the source (and transmitted to a replica that does not support deferred unique key updates) as shown here:

```
CREATE TABLE t (
 p INT PRIMARY KEY,
 c INT,
 UNIQUE KEY u (c)
) ENGINE NDB;

INSERT INTO t
VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following [UPDATE](#) statement on `t` succeeds on the source, since the rows affected are processed in the order determined by the [ORDER BY](#) option, performed over the entire table:

```
UPDATE t SET c = c - 1 ORDER BY p;
```

The same statement fails with a duplicate key error or other constraint violation on the replica, because the ordering of the row updates is performed for one partition at a time, rather than for the table as a whole.

#### Note

Every [NDB](#) table is implicitly partitioned by key when it is created. See [Section 22.2.5, “KEY Partitioning”](#), for more information.

**GTIDs not supported.** Replication using global transaction IDs is not compatible with the [NDB](#) storage engine, and is not supported. Enabling GTIDs is likely to cause NDB Cluster Replication to fail.

**Multithreaded replicas not supported.** NDB Cluster does not support multithreaded replicas, and setting related system variables such as `slave_parallel_workers`, `slave_checkpoint_group`, and `slave_checkpoint_group` (or the equivalent `mysqld` startup options) has no effect.

This is because the replica may not be able to separate transactions occurring in one database from those in another if they are written within the same epoch. In addition, every transaction handled by the [NDB](#) storage engine involves at least two databases—the target database and the `mysql` system database—due to the requirement for updating the `mysql.ndb_apply_status` table (see [Section 21.6.4, “NDB Cluster Replication Schema and Tables”](#)). This in turn breaks the requirement for multithreading that the transaction is specific to a given database.

**Restarting with --initial.** Restarting the cluster with the [--initial](#) option causes the sequence of GCI and epoch numbers to start over from `0`. (This is generally true of NDB Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the `RESET MASTER` and `RESET SLAVE` statements to clear the invalid `ndb_binlog_index` and `ndb_apply_status` tables, respectively.

**Replication from NDB to other storage engines.** It is possible to replicate an [NDB](#) table on the source to a table using a different storage engine on the replica, taking into account the restrictions listed here:

- Multi-source and circular replication are not supported (tables on both the source and the replica must use the [NDB](#) storage engine for this to work).
- Using a storage engine which does not perform binary logging for tables on the replica requires special handling.
- Use of a nontransactional storage engine for tables on the replica also requires special handling.

- The source `mysqld` must be started with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`.

The next few paragraphs provide additional information about each of the issues just described.

**Multiple sources not supported when replicating NDB to other storage engines.** For replication from `NDB` to a different storage engine, the relationship between the two databases must be one-to-one. This means that bidirectional or circular replication is not supported between NDB Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between `NDB` and a different storage engine. (An NDB Cluster database *can* simultaneously replicate to multiple NDB Cluster databases.) If the source uses `NDB` tables, it is still possible to have more than one MySQL Server maintain a binary log of all changes, but for the replica to change sources (fail over), the new source-replica relationship must be explicitly defined on the replica.

**Replicating NDB tables to a storage engine that does not perform binary logging.** If you attempt to replicate from an NDB Cluster to a replica that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `Binary logging not possible ... Statement cannot be written atomically since more than one engine involved and at least one engine is self-logging` (Error 1595). It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the replica.** This can be accomplished by setting `sql_log_bin = 0`.
- **Change the storage engine used for the `mysql.ndb_apply_status` table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the replica. It is safe to do this when using a storage engine other than `NDB` on the replica, since you do not need to worry about keeping multiple replicas synchronized.
- **Filter out changes to the `mysql.ndb_apply_status` table on the replica.** This can be done by starting the replica with `--replicate-ignore-table=mysql.ndb_apply_status`. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

#### Important

You should *not* disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one NDB Cluster to another. See [Replication and binary log filtering rules with replication between NDB Clusters](#), for details.

**Replication from NDB to a nontransactional storage engine.** When replicating from `NDB` to a nontransactional storage engine such as `MyISAM`, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these by using `--ndb-log-update-as-write=0`, which forces updates to be logged as writes, rather than as updates.

**Replication and binary log filtering rules with replication between NDB Clusters.** If you are using any of the options `--replicate-do-*`, `--replicate-ignore-*`, `--binlog-do-db`, or `--binlog-ignore-db` to filter databases or tables being replicated, you must take care not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between NDB Clusters to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=db_name` (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that *only* tables in database `db_name` are replicated. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on replicas.

Using `--binlog-do-db=db_name` (and no other `--binlog-do-db` options) means that changes *only* to tables in database `db_name` are written to the binary log. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on replicas.

2. Using `--replicate-ignore-db=mysql` means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

Using `--binlog-ignore-db=mysql` means that no changes to tables in the `mysql` database are written to the binary log. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

You should also remember that each replication rule requires the following:

1. Its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see [Section 16.1.6, “Replication and Binary Logging Options and Variables”](#).
2. Its own `--binlog-do-db` or `--binlog-ignore-db` option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see [Section 5.4.4, “The Binary Log”](#).

If you are replicating an NDB Cluster to a replica that uses a storage engine other than `NDB`, the considerations just given previously may not apply, as discussed elsewhere in this section.

**NDB Cluster Replication and IPv6.** While the NDB API and MGM API (and thus data nodes and management nodes) do not support IPv6 in NDB 7.5 and 7.6, MySQL Servers—including those acting as SQL nodes in an NDB Cluster—can use IPv6 to contact other MySQL Servers. This means that you can replicate between NDB Clusters using IPv6 to connect the source and replica SQL nodes as shown by the dotted arrow in the following diagram:

**Figure 21.46 Replication Between SQL Nodes Connected Using IPv6**

All connections originating *within* the NDB Cluster—represented in the preceding diagram by solid arrows—must use IPv4. In other words, all NDB Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster.

Since there is currently no support in the NDB and MGM APIs for IPv6, any applications written using these APIs must also make all connections using IPv4.

**Attribute promotion and demotion.** NDB Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the replica can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion in NDB Cluster, see [Row-based replication: attribute promotion and demotion](#).

NDB, unlike [InnoDB](#) or [MyISAM](#), does not write changes to virtual columns to the binary log; however, this has no detrimental effects on NDB Cluster Replication or replication between NDB and other storage engines. Changes to stored generated columns are logged.

## 21.6.4 NDB Cluster Replication Schema and Tables

- [ndb\\_apply\\_status Table](#)
- [ndb\\_binlog\\_index Table](#)
- [ndb\\_replication Table](#)

Replication in NDB Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and in the replica. This is true regardless of whether the replica is a single server or a cluster.

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database. They should not be explicitly replicated by the user. User intervention is normally not required to create or maintain either of these tables, since both are maintained by the NDB binary log (binlog) injector thread. This keeps the source `mysqld` process updated to changes performed by the NDB storage engine. The NDB binlog injector thread receives events directly from the NDB storage engine. The NDB injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the `ndb_binlog_index` table. The replica I/O thread transfers the events from the source's binary log to the replica's relay log.

The `ndb_replication` table must be created manually. This table can be updated by the user to perform filtering by database or table. See [ndb\\_replication Table](#), for more information. `ndb_replication` is also used in NDB Replication conflict detection and resolution for conflict resolution control; see [Conflict Resolution Control](#).

Even though `ndb_binlog_index` and `ndb_apply_status` are created and maintained automatically, it is advisable to check for the existence and integrity of these tables as an initial step in preparing an NDB Cluster for replication. It is possible to view event data recorded in the binary log by querying the `mysql.ndb_binlog_index` table directly on the source. This can be also be accomplished using the `SHOW BINLOG EVENTS` statement on either the source or replica SQL node. (See [Section 13.7.5.2, “SHOW BINLOG EVENTS Statement”](#).)

You can also obtain useful information from the output of `SHOW ENGINE NDB STATUS`.

### Note

When performing schema changes on NDB tables, applications should wait until the `ALTER TABLE` statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

### ndb\_apply\_status Table

`ndb_apply_status` is used to keep a record of the operations that have been replicated from the source to the replica. If the `ndb_apply_status` table does not exist on the replica, `ndb_restore` recreates it.

Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (replica) cluster, and so `ndb_apply_status` can use the `NDBCLUSTER` storage engine, as shown here:

```
CREATE TABLE `ndb_apply_status` (
 `server_id` INT(10) UNSIGNED NOT NULL,
 `epoch` BIGINT(20) UNSIGNED NOT NULL,
 `log_name` VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,
 `start_pos` BIGINT(20) UNSIGNED NOT NULL,
 `end_pos` BIGINT(20) UNSIGNED NOT NULL,
 PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;
```

The `ndb_apply_status` table is populated only on replicas, which means that, on the source, this table never contains any rows; thus, there is no need to allot any `DataMemory` to `ndb_apply_status` there.

Because this table is populated from data originating on the source, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the replica from updating `ndb_apply_status`, or that prevent the source from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see [Replication and binary log filtering rules with replication between NDB Clusters](#).

## ndb\_binlog\_index Table

NDB Cluster Replication uses the `ndb_binlog_index` table for storing the binary log's indexing data. Since this table is local to each MySQL server and does not participate in clustering, it uses the `InnoDB` storage engine. This means that it must be created separately on each `mysqld` participating in the source cluster. (The binary log itself contains updates from all MySQL servers in the cluster.) This table is defined as follows:

```
CREATE TABLE `ndb_binlog_index` (
 `Position` BIGINT(20) UNSIGNED NOT NULL,
 `File` VARCHAR(255) NOT NULL,
 `epoch` BIGINT(20) UNSIGNED NOT NULL,
 `inserts` INT(10) UNSIGNED NOT NULL,
 `updates` INT(10) UNSIGNED NOT NULL,
 `deletes` INT(10) UNSIGNED NOT NULL,
 `schemaops` INT(10) UNSIGNED NOT NULL,
 `orig_server_id` INT(10) UNSIGNED NOT NULL,
 `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,
 `gci` INT(10) UNSIGNED NOT NULL,
 `next_position` bigint(20) unsigned NOT NULL,
 `next_file` varchar(255) NOT NULL,
 PRIMARY KEY (`epoch`, `orig_server_id`, `orig_epoch`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

### Note

Prior to NDB 7.5.2, this table always used the `MyISAM` storage engine. If you are upgrading from an earlier release, you can use `mysql_upgrade` with the `--force` and `--upgrade-system-tables` options after starting the server.) The system table upgrade causes an `ALTER TABLE ... ENGINE=INNODB` statement to be executed for this table. Use of the `MyISAM` storage engine for this table continues to be supported for backward compatibility.

`ndb_binlog_index` may require additional disk space after being converted to `InnoDB`. If this becomes an issue, you may be able to conserve space by using an `InnoDB` tablespace for this table, changing its `ROW_FORMAT` to `COMPRESSED`, or both. For more information, see [Section 13.1.19, “CREATE TABLESPACE Statement”](#), and [Section 13.1.18, “CREATE TABLE Statement”](#), as well as [Section 14.6.3, “Tablespaces”](#).

The size of the `ndb_binlog_index` table is dependent on the number of epochs per binary log file and the number of binary log files. The number of epochs per binary log file normally depends on the amount of binary log generated per epoch and the size of the binary log file, with smaller epochs resulting in more epochs per file. You should be aware that empty epochs produce inserts to the `ndb_binlog_index` table, even when the `--ndb-log-empty-epochs` option is `OFF`, meaning that the number of entries per file depends on the length of time that the file is in use; this relationship can be represented by the formula shown here:

```
[number of epochs per file] = [time spent per file] / TimeBetweenEpochs
```

A busy NDB Cluster writes to the binary log regularly and presumably rotates binary log files more quickly than a quiet one. This means that a “quiet” NDB Cluster with `--ndb-log-empty-epochs=ON` can actually have a much higher number of `ndb_binlog_index` rows per file than one with a great deal of activity.

When `mysqld` is started with the `--ndb-log-orig` option, the `orig_server_id` and `orig_epoch` columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server, which is useful in NDB Cluster replication setups employing multiple sources. The `SELECT` statement used to find the closest binary log position to the highest applied epoch on the replica in a multi-source setup (see [Section 21.6.10, “NDB Cluster Replication: Bidirectional and Circular Replication”](#)) employs these two columns, which are not indexed. This can lead to performance issues when trying to fail over, since the query must perform a table scan, especially when the source has been running with `--ndb-log-empty-epochs=ON`. You can improve multi-source failover times by adding an index to these columns, as shown here:

```
ALTER TABLE mysql.ndb_binlog_index
 ADD INDEX orig_lookup USING BTREE (orig_server_id, orig_epoch);
```

Adding this index provides no benefit when replicating from a single source to a single replica, since the query used to get the binary log position in such cases makes no use of `orig_server_id` or `orig_epoch`.

See [Section 21.6.8, “Implementing Failover with NDB Cluster Replication”](#), for more information about using the `next_position` and `next_file` columns.

The following figure shows the relationship of the NDB Cluster replication source server, its binary log injector thread, and the `mysql.ndb_binlog_index` table.

**Figure 21.47 The Replication Source Cluster****MySQL Replication Between Clusters, Injecting into Binlog****ndb\_replication Table**

The `ndb_replication` table is used to control binary logging and conflict resolution, and acts on a per-table basis. Each row in this table corresponds to a table being replicated, determines how to log changes to the table and, if a conflict resolution function is specified, and determines how to resolve conflicts for that table.

Unlike the `ndb_apply_status` and `ndb_replication` tables, the `ndb_replication` table must be created manually. You can do this by using the SQL statement shown here:

```
CREATE TABLE mysql.ndb_replication (
 db VARBINARY(63),
 table_name VARBINARY(63),
 server_id INT UNSIGNED,
 binlog_type INT UNSIGNED,
 conflict_fn VARBINARY(128),
 PRIMARY KEY USING HASH (db, table_name, server_id)
) ENGINE=NDB
PARTITION BY KEY(db,table_name);
```

The columns of this table are listed here, with descriptions:

- `db` column

The name of the database containing the table to be replicated. You may employ either or both of the wildcards `_` and `%` as part of the database name. Matching is similar to what is implemented for the `LIKE` operator.

- `table_name` column

The name of the table to be replicated. The table name may include either or both of the wildcards `_` and `%`. Matching is similar to what is implemented for the `LIKE` operator.

- `server_id` column

The unique server ID of the MySQL instance (SQL node) where the table resides.

- `binlog_type` column

The type of binary logging to be employed. See text for values and descriptions.

- `conflict_fn` column

The conflict resolution function to be applied; one of `NDB$OLD(column_name)`, `NDB$MAX(column_name)`, `NDB$MAX_DELETE_WIN()`, `NDB$EPOCH()`, `NDB$EPOCH_TRANS()`, `NDB$EPOCH2()`, `NDB$EPOCH2_TRANS()`; `NULL` indicates that conflict resolution is not used for this table.

See [Conflict Resolution Functions](#), for more information about these functions and their uses in NDB Replication conflict resolution.

Some conflict resolution functions (`NDB$OLD()`, `NDB$EPOCH()`, `NDB$EPOCH_TRANS()`) require the use of one or more user-created exceptions tables. See [Conflict Resolution Exceptions Table](#).

To enable conflict resolution with NDB Replication, it is necessary to create and populate this table with control information on the SQL node or nodes on which the conflict should be resolved. Depending on the conflict resolution type and method to be employed, this may be the source, the replica, or both servers. In a simple source-replica setup where data can also be changed locally on the replica this is typically the replica. In a more complex replication scheme, such as bidirectional replication, this is usually all of the sources involved. See [Section 21.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

The `ndb_replication` table allows table-level control over binary logging outside the scope of conflict resolution, in which case `conflict_fn` is specified as `NULL`, while the remaining column values are used to control binary logging for a given table or set of tables matching a wildcard expression. By setting the proper value for the `binlog_type` column, you can make logging for a given table or tables use a desired binary log format, or disabling binary logging altogether. Possible values for this column, with internal values and descriptions, are shown in the following table:

**Table 21.65 binlog\_type values, with internal values and descriptions**

| Value | Internal Value                                                                                                   | Description                                                                                                                              |
|-------|------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | <code>NBT_DEFAULT</code>                                                                                         | Use server default                                                                                                                       |
| 1     | <code>NBT_NO_LOGGING</code>                                                                                      | Do not log this table in the binary log                                                                                                  |
| 2     | <code>NBT_UPDATED_ONL</code>                                                                                     | Only updated attributes are logged                                                                                                       |
| 3     | <code>NBT_FULL</code>                                                                                            | Log full row, even if not updated (MySQL server default behavior)                                                                        |
| 4     | <code>NBT_USE_UPDATE</code>                                                                                      | (For generating <code>NBT_UPDATED_ONLY_USE_UPDATE</code> and <code>NBT_FULL_USE_UPDATE</code> values only—not intended for separate use) |
| 5     | [Not used]                                                                                                       | ---                                                                                                                                      |
| 6     | <code>NBT_UPDATED_ONL</code><br>(equal to<br><code>NBT_UPDATED_ONLY</code><br> <br><code>NBT_USE_UPDATE</code> ) | Use updated attributes, even if values are unchanged                                                                                     |
| 7     | <code>NBT_FULL_USE_UPD</code><br>(equal to<br><code>NBT_FULL</code>  <br><code>NBT_USE_UPDATE</code> )           | Use full row, even if values are unchanged                                                                                               |
| 8     | <code>NBT_UPDATED_ONL</code>                                                                                     | Log update as <code>UPDATE_ROW</code> ; log only primary key columns in before image, and only updated columns in after image            |

| Value | Internal Value   | Description                                                                                                                           |
|-------|------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| 9     | NBT_UPDATED_FULL | Log update as UPDATE_ROW; log only primary key columns in before image, and all columns other than primary key columns in after image |

Binary logging can be set to different formats for different tables by inserting rows into the `ndb_replication` table using the appropriate `db`, `table_name`, and `binlog_type` column values. The internal integer value shown in the preceding table should be used when setting the binary logging format. The following two statements set binary logging to logging of full rows (`NBT_FULL`, internal value 3) for table `test.a`, and to logging of updates only (`NBT_UPDATED_ONLY`, internal value 2) for table `test.b`:

```
Table test.a: Log full rows
INSERT INTO mysql.ndb_replication VALUES("test", "a", 0, 3, NULL);

Table test.b: log updates only
INSERT INTO mysql.ndb_replication VALUES("test", "b", 0, 2, NULL);
```

To disable logging for one or more tables, use 1 (`NBT_NO_LOGGING`) for `binlog_type`, as shown here:

```
Disable binary logging for table test.t1
INSERT INTO mysql.ndb_replication VALUES("test", "t1", 0, 1, NULL);

Disable binary logging for any table in 'test' whose name begins with 't'
INSERT INTO mysql.ndb_replication VALUES("test", "t%", 0, 1, NULL);
```

## 21.6.5 Preparing the NDB Cluster for Replication

Preparing the NDB Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see [Section 21.6.2, “General Requirements for NDB Cluster Replication”](#)).
2. Create a replication account on the source Cluster with the appropriate privileges, using the following two SQL statements:

```
mysqlS> CREATE USER 'replica_user'@'replica_host'
 -> IDENTIFIED BY 'replica_password';

mysqlS> GRANT REPLICATION SLAVE ON *.*
 -> TO 'replica_user'@'replica_host';
```

In the previous statement, `replica_user` is the replication account user name, `replica_host` is the host name or IP address of the replica, and `replica_password` is the password to assign to this account.

For example, to create a replica user account with the name `myreplica`, logging in from the host named `replica-host`, and using the password `53cr37`, use the following `CREATE_USER` and `GRANT` statements:

```
mysqlS> CREATE USER 'myreplica'@'replica-host'
 -> IDENTIFIED BY '53cr37';

mysqlS> GRANT REPLICATION SLAVE ON *.*
 -> TO 'myreplica'@'replica-host';
```

For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication account.

3. Set up the replica to use the source. Using the `mysql` client, this can be accomplished with the the following `CHANGE MASTER TO` statement:

```
mysqlR> CHANGE MASTER TO
 -> MASTER_HOST='source_host',
```

```
--> MASTER_PORT=source_port,
--> MASTER_USER='replica_user',
--> MASTER_PASSWORD='replica_password';
```

In the previous statement, `source_host` is the host name or IP address of the replication source, `source_port` is the port for the replica to use when connecting to the source, `replica_user` is the user name set up for the replica on the source, and `replica_password` is the password set for that user account in the previous step.

For example, to tell the replica to use the MySQL server whose host name is `rep-source` with the replication account created in the previous step, use the following statement:

```
mysqlR> CHANGE MASTER TO
 -> MASTER_HOST='rep-source',
 -> MASTER_PORT=3306,
 -> MASTER_USER='myreplica',
 -> MASTER_PASSWORD='53cr37';
```

For a complete list of options that can be used with this statement, see [Section 13.4.2.1, “CHANGE MASTER TO Statement”](#).

To provide replication backup capability, you also need to add an `--ndb-connectstring` option to the replica's `my.cnf` file prior to starting the replication process. See [Section 21.6.9, “NDB Cluster Backups With NDB Cluster Replication”](#), for details.

For additional options that can be set in `my.cnf` for replicas, see [Section 16.1.6, “Replication and Binary Logging Options and Variables”](#).

4. If the source cluster is already in use, you can create a backup of the source and load this onto the replica to cut down on the amount of time required for the replica to synchronize itself with the source. If the replica is also running NDB Cluster, this can be accomplished using the backup and restore procedure described in [Section 21.6.9, “NDB Cluster Backups With NDB Cluster Replication”](#).

```
ndb-connectstring=management_host[:port]
```

In the event that you are *not* using NDB Cluster on the replica, you can create a backup with this command on the source:

```
shellS> mysqldump --master-data=1
```

Then import the resulting data dump onto the replica by copying the dump file over to it. After this, you can use the `mysql` client to import the data from the dumpfile into the replica database as shown here, where `dump_file` is the name of the file that was generated using `mysqldump` on the source, and `db_name` is the name of the database to be replicated:

```
shellR> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

### Note

If you copy the data to the replica in this fashion, you should make sure that the replica is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the replica's `my.cnf` file to keep it from trying to connect to the source to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication source is assigned a unique server ID, and has binary logging enabled, using the row-based format. (See [Section 16.2.1, “Replication Formats”](#).) In addition, we recommend enabling the `slave_allow_batching` system variable,

and possibly increasing the values used with the `--ndb-batch-size` and `--ndb-blob-write-batch-bytes` options as well. All of these options can be set either in the source server's `my.cnf` file, or on the command line when starting the source `mysqld` process. See [Section 21.6.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”,](#) for more information.

## 21.6.6 Starting NDB Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting NDB Cluster replication using a single replication channel.

1. Start the MySQL replication source server by issuing this command:

```
shellS> mysqld --ndbcluster --server-id=id \
 --log-bin --ndb-log-bin &
```

In the previous statement, `id` is this server's unique ID (see [Section 21.6.2, “General Requirements for NDB Cluster Replication”](#)). This starts the server's `mysqld` process with binary logging enabled using the proper logging format.

### Note

You can also start the source with `--binlog-format=MIXED`, in which case row-based replication is used automatically when replicating between clusters. Statement-based binary logging is not supported for NDB Cluster Replication (see [Section 21.6.2, “General Requirements for NDB Cluster Replication”](#)).

2. Start the MySQL replica server as shown here:

```
shellR> mysqld --ndbcluster --server-id=id &
```

In the command just shown, `id` is the replica server's unique ID. It is not necessary to enable logging on the replica.

### Note

You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the replica server's `my.cnf` file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the replica server with the source server's replication binary log. If binary logging has not previously been running on the source, run the following statement on the replica:

```
mysqlR> CHANGE MASTER TO
 -> MASTER_LOG_FILE='',
 -> MASTER_LOG_POS=4;
```

This instructs the replica to begin reading the source server's binary log from the log's starting point. Otherwise—that is, if you are loading data from the source using a backup—see [Section 21.6.8, “Implementing Failover with NDB Cluster Replication”](#), for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

4. Finally, instruct the replica to begin applying replication by issuing this command from the `mysql` client on the replica:

```
mysqlR> START SLAVE;
```

This also initiates the transmission of data and changes from the source to the replica.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in [Section 21.6.7, “Using Two Replication Channels for NDB Cluster Replication”](#).

It is also possible to improve cluster replication performance by enabling *batched updates*. This can be accomplished by setting the `slave_allow_batching` system variable on the replicas' `mysqld` processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in batches of 32 KB each; this can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

#### Note

Batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```
mysql> SHOW VARIABLES LIKE 'slave%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| slave_allow_batching | ON |
| slave_compressed_protocol | OFF |
| slave_load_tmpdir | /tmp |
| slave_net_timeout | 3600 |
| slave_skip_errors | OFF |
| slave_transaction_retries | 10 |
+-----+-----+
6 rows in set (0.00 sec)
```

## 21.6.7 Using Two Replication Channels for NDB Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two source servers on the source cluster and two replica servers on the replica cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

**Table 21.66 NDB Cluster replication servers described in the text**

| Server ID | Description                                 |
|-----------|---------------------------------------------|
| 1         | Source - primary replication channel (S)    |
| 2         | Source - secondary replication channel (S') |

| Server ID | Description                                           |
|-----------|-------------------------------------------------------|
| 3         | Replica - primary replication channel ( <i>R</i> )    |
| 4         | replica - secondary replication channel ( <i>R'</i> ) |

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication source servers must be started, followed by those for the primary and secondary replicas. The replication processes can be initiated by issuing the `START SLAVE` statement on each of the replicas. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication source:

```
shellS> mysqld --ndbcluster --server-id=1 \
--log-bin &
```

2. Start the secondary replication source:

```
shellS'> mysqld --ndbcluster --server-id=2 \
--log-bin &
```

3. Start the primary replica server:

```
shellR> mysqld --ndbcluster --server-id=3 \
--skip-slave-start &
```

4. Start the secondary replica server:

```
shellR'> mysqld --ndbcluster --server-id=4 \
--skip-slave-start &
```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary replica as shown here:

```
mysqlR> START SLAVE;
```

#### Warning

Only the primary channel must be started at this point. The secondary replication channel needs to be started only in the event that the primary replication channel fails, as described in [Section 21.6.8, “Implementing Failover with NDB Cluster Replication”](#). Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replicas.

As mentioned previously, it is not necessary to enable binary logging on the replicas.

### 21.6.8 Implementing Failover with NDB Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the `ndb_apply_status` table on the replica cluster, which can be found using the following query:

```
mysqlR'> SELECT @latest:=MAX(epoch)
-> FROM mysql.ndb_apply_status;
```

In a circular replication topology, with a source and a replica running on each host, when you are using `ndb_log_apply_status=1`, NDB Cluster epochs are written in the replicas' binary logs. This means that the `ndb_apply_status` table contains information for the replica on this host as

well as for any other host which acts as a replica of the replication source server running on this host.

In this case, you need to determine the latest epoch on this replica to the exclusion of any epochs from any other replicas in this replica's binary log that were not listed in the `IGNORE_SERVER_IDS` options of the `CHANGE MASTER TO` statement used to set up this replica. The reason for excluding such epochs is that rows in the `mysql.ndb_apply_status` table whose server IDs have a match in the `IGNORE_SERVER_IDS` list from the `CHANGE MASTER TO` statement used to prepare this replica's source are also considered to be from local servers, in addition to those having the replica's own server ID. You can retrieve this list as `Replicate_Ignore_Server_Ids` from the output of `SHOW SLAVE STATUS`. We assume that you have obtained this list and are substituting it for `ignore_server_ids` in the query shown here, which like the previous version of the query, selects the greatest epoch into a variable named `@latest`:

```
mysqlR' > SELECT @latest:=MAX(epoch)
 -> FROM mysql.ndb_apply_status
 -> WHERE server_id NOT IN (ignore_server_ids);
```

In some cases, it may be simpler or more efficient (or both) to use a list of the server IDs to be included and `server_id IN server_id_list` in the `WHERE` condition of the preceding query.

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the `ndb_binlog_index` table on the source cluster.

You can use the following query to obtain the needed records from the `ndb_binlog_index` table on the source:

```
mysqlS' > SELECT
 -> @file:=SUBSTRING_INDEX(next_file, '/', -1),
 -> @pos:=next_position
 -> FROM mysql.ndb_binlog_index
 -> WHERE epoch >= @latest
 -> ORDER BY epoch ASC LIMIT 1;
```

These are the records saved on the source since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be "plugged in" to the second query manually or by an application.

### Important

You must ensure that the replica `mysqld` is started with `--slave-skip-errors=ddl_exist_errors` before executing `START SLAVE`. Otherwise, replication may stop with duplicate DDL errors.

3. Now it is possible to synchronize the secondary channel by running the following query on the secondary replica server:

```
mysqlR' > CHANGE MASTER TO
 -> MASTER_LOG_FILE='@file',
 -> MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using an application that can access both of the servers involved.

### Note

`@file` is a string value such as `'/var/log/mysqlreplication-source-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must *not* be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate statement on the secondary replica `mysqld`:

```
mysqlR' > START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this depend upon the reasons for which the primary channel failed.

### Warning

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replicas.

If the failure is limited to a single server, it should in theory be possible to replicate from *S* to *R'*, or from *S'* to *R*.

## 21.6.9 NDB Cluster Backups With NDB Cluster Replication

This section discusses making backups and restoring from them using NDB Cluster replication. We assume that the replication servers have already been configured as covered previously (see [Section 21.6.5, “Preparing the NDB Cluster for Replication”](#), and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.
  - **Method A.** This method requires that the cluster backup process was previously enabled on the source server, prior to starting the replication process. This can be done by including the following line in a `[mysql_cluster]` section in the `my.cnf` file, where `management_host` is the IP address or host name of the `NDB` management server for the source cluster, and `port` is the management server's port number:

```
ndb-connectstring=management_host[:port]
```

### Note

The port number needs to be specified only if the default port (1186) is not being used. See [Section 21.2.3, “Initial Configuration of NDB Cluster”](#), for more information about ports and port allocation in NDB Cluster.

In this case, the backup can be started by executing this statement on the replication source:

```
shellS> ndb_mgm -e "START BACKUP"
```

- **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the `NDB` management client as part of the `START BACKUP` command. This can be done as shown here, where `management_host` and `port` are the host name and port number of the management server:

```
shellS> ndb_mgm management_host:port -e "START BACKUP"
```

In our scenario as outlined earlier (see [Section 21.6.5, “Preparing the NDB Cluster for Replication”](#)), this would be executed as follows:

```
shellS> ndb_mgm rep-source:1186 -e "START BACKUP"
```

2. Copy the cluster backup files to the replica that is being brought on line. Each system running an `ndbd` process for the source cluster has cluster backup files located on it, and *all* of these files must be copied to the replica to ensure a successful restore. The backup files can be copied into any directory on the computer where the replica's management host resides, as long as the MySQL and

NDB binaries have read permissions in that directory. In this case, we assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

While it is not necessary that the replica cluster have the same number of `ndbd` processes (data nodes) as the source, it is highly recommended this number be the same. It *is* necessary that the replica be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the replica cluster that are present on the source cluster and that are to be replicated.

#### **Important**

A `CREATE DATABASE` (or `CREATE SCHEMA`) statement corresponding to each database to be replicated must be executed on each SQL node in the replica cluster.

4. Reset the replica cluster using this statement in the `mysql` client:

```
mysqlR> RESET SLAVE;
```

5. You can now start the cluster restoration process on the replica using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata, as shown here:

```
shellR> ndb_restore -c replica_host:port -n node-id \
 -b backup-id -m -r dir
```

`dir` is the path to the directory where the backup files have been placed on the replica. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

For restoring from a source cluster with four data nodes (as shown in the figure in [Section 21.6, “NDB Cluster Replication”](#)) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the replica might look like this:

```
shellR> ndb_restore -c replica-host:1186 -n 2 -b 1 -m \
 -r ./var/BACKUPS/BACKUP-1
shellR> ndb_restore -c replica-host:1186 -n 3 -b 1 \
 -r ./var/BACKUPS/BACKUP-1
shellR> ndb_restore -c replica-host:1186 -n 4 -b 1 \
 -r ./var/BACKUPS/BACKUP-1
shellR> ndb_restore -c replica-host:1186 -n 5 -b 1 -e \
 -r ./var/BACKUPS/BACKUP-1
```

#### **Important**

The `-e` (or `--restore-epoch`) option in the final invocation of `ndb_restore` in this example is required to make sure that the epoch is written to the replica's `mysql.ndb_apply_status` table. Without this information, the replica cannot synchronize properly with the source. (See [Section 21.4.24, “ndb\\_restore — Restore an NDB Cluster Backup”](#).)

6. Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the replica (as discussed in [Section 21.6.8, “Implementing Failover with NDB Cluster Replication”](#)):

```
mysqlR> SELECT @latest:=MAX(epoch)
 FROM mysql.ndb_apply_status;
```

7. Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the `mysql.ndb_binlog_index` table on the source using the query shown here:

```
mysqlS> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE epoch >= @latest
-> ORDER BY epoch ASC LIMIT 1;
```

In the event that there is currently no replication traffic, you can get this information by running `SHOW MASTER STATUS` on the source and using the value shown in the `Position` column of the output for the file whose name has the suffix with the greatest value for all files shown in the `File` column. In this case, you must determine which file this is and supply the name in the next step manually or by parsing the output with a script.

8. Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the replica's `mysql` client:

```
mysqlR> CHANGE MASTER TO
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

9. Now that the replica knows from what point in which binary log file to start reading data from the source, you can cause the replica to begin replicating with this statement:

```
mysqlR> START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary source and replica for those of the primary source and replica servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see [Section 21.5.8, “Online Backup of NDB Cluster”](#).

### 21.6.9.1 NDB Cluster Replication: Automating Synchronization of the Replica to the Source Binary Log

It is possible to automate much of the process described in the previous section (see [Section 21.6.9, “NDB Cluster Backups With NDB Cluster Replication”](#)). The following Perl script `reset-replica.pl` serves as an example of how you can do this.

```
#!/user/bin/perl -w

### 21.6.9.2 Point-In-Time Recovery Using NDB Cluster Replication

*Point-in-time* recovery—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing point-in-time recovery of NDB Cluster tables with NDB Cluster and NDB Cluster Replication can be accomplished using a native NDB data backup (taken by issuing `CREATE BACKUP` in the `ndb_mgm` client) and restoring the `mysql.ndb_binlog_index` table (from a dump made using `mysqldump`).

To perform point-in-time recovery of NDB Cluster, it is necessary to follow the steps shown here:

1. Back up all NDB databases in the cluster, using the `START BACKUP` command in the `ndb_mgm` client (see [Section 21.5.8, “Online Backup of NDB Cluster”](#)).
2. At some later point, prior to restoring the cluster, make a backup of the `mysql.ndb_binlog_index` table. It is probably simplest to use `mysqldump` for this task. Also back up the binary log files at this time.

This backup should be updated regularly—perhaps even hourly—depending on your needs.

3. (*Catastrophic failure or error occurs.*)
4. Locate the last known good backup.
5. Clear the data node file systems (using `ndbd --initial` or `ndbmttd --initial`).

#### Note

NDB Cluster Disk Data tablespace and log files are not removed by `--initial`. You must delete these manually.

6. Use `DROP TABLE` or `TRUNCATE TABLE` with the `mysql.ndb_binlog_index` table.
7. Execute `ndb_restore`, restoring all data. You must include the `--restore-epoch` option when you run `ndb_restore`, so that the `ndb_apply_status` table is populated correctly. (See [Section 21.4.24, “ndb\\_restore — Restore an NDB Cluster Backup”](#), for more information.)
8. Restore the `ndb_binlog_index` table from the output of `mysqldump` and restore the binary log files from backup, if necessary.
9. Find the epoch applied most recently—that is, the maximum `epoch` column value in the `ndb_apply_status` table—as the user variable `@LATEST_EPOCH` (emphasized):

```

SELECT @LATEST_EPOCH:=MAX(epoch)
 FROM mysql.ndb_apply_status;

```

10. Find the latest binary log file (`@FIRST_FILE`) and position (`Position` column value) within this file that correspond to `@LATEST_EPOCH` in the `ndb_binlog_index` table:

```

SELECT Position, @FIRST_FILE:=File
 FROM mysql.ndb_binlog_index
 WHERE epoch > @LATEST_EPOCH ORDER BY epoch ASC LIMIT 1;

```

11. Using `mysqlbinlog`, replay the binary log events from the given file and position up to the point of the failure. (See [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).)

See also [Section 7.5, “Point-in-Time \(Incremental\) Recovery”](#), for more information about the binary log, replication, and incremental recovery.

## 21.6.10 NDB Cluster Replication: Bidirectional and Circular Replication

It is possible to use NDB Cluster for bidirectional replication between two clusters, as well as for circular replication between any number of clusters.

**Circular replication example.** In the next few paragraphs we consider the example of a replication setup involving three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication source for Cluster 2, Cluster 2 acts as the source for Cluster 3, and Cluster 3 acts as the source for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all sources and replicas are the same.
- All SQL nodes acting as sources and replicas are started with the `log_slave_updates` system variable enabled.

This type of circular replication setup is shown in the following diagram:

**Figure 21.48 NDB Cluster Circular Replication with All Sources As Replicas**

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line

(indicated by the curved arrows in the diagram) directly connects all SQL nodes used as replication sources and replicas.

It is also possible to set up circular replication in such a way that not all source SQL nodes are also replicas, as shown here:

**Figure 21.49 NDB Cluster Circular Replication Where Not All Sources Are Replicas**

In this case, different SQL nodes in each cluster are used as replication sources and replicas. You must *not* start any of the SQL nodes with the `log_slave_updates` system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Using NDB-native backup and restore to initialize a replica cluster.** When setting up circular replication, it is possible to initialize the replica cluster by using the management client `START BACKUP` command on one NDB Cluster to create a backup and then applying this backup on another NDB Cluster using `ndb_restore`. This does not automatically create binary logs on the second NDB Cluster's SQL node acting as the replica; in order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START SLAVE`. This is a known issue.

**Multi-source failover example.** In this section, we discuss failover in a multi-source NDB Cluster replication setup with three NDB Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:

**Figure 21.50 NDB Cluster Multi-Master Replication With 3 Sources**

In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-source replication must act as both source and replica, and a given NDB Cluster might use different SQL nodes for different replication channels. Such a case is shown here:

**Figure 21.51 NDB Cluster Multi-Source Replication, With MySQL Servers**

MySQL servers acting as replicas must be run with the `log_slave_updates` system variable enabled. Which `mysqld` processes require this option is also shown in the preceding diagram.

#### Note

Using the `log_slave_updates` system variable has no effect on servers not being run as replicas.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1. Because replication between NDB Clusters is asynchronous, there is no guarantee that Cluster 3's updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.

On server C, perform the following queries:

```
mysqlC> SELECT @latest:=MAX(epoch)
-> FROM mysql.ndb_apply_status
-> WHERE server_id=1;

mysqlC> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE orig_epoch >= @latest
-> AND orig_server_id = 1
-> ORDER BY epoch ASC LIMIT 1;
```

**Note**

You can improve the performance of this query, and thus likely speed up failover times significantly, by adding the appropriate index to the `ndb_binlog_index` table. See [Section 21.6.4, “NDB Cluster Replication Schema and Tables”](#), for more information.

Copy over the values for `@file` and `@pos` manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```
mysqlF> CHANGE MASTER TO
-> MASTER_HOST = 'serverC'
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START SLAVE` statement on MySQL server F; this causes any missing updates originating from server B to be replicated to server F.

The `CHANGE MASTER TO` statement also supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see [Section 13.4.2.1, “CHANGE MASTER TO Statement”](#), and [Section 13.7.5.34, “SHOW SLAVE STATUS Statement”](#). For information about how this option interacts with the `ndb_log_apply_status` variable, see [Section 21.6.8, “Implementing Failover with NDB Cluster Replication”](#).

## 21.6.11 NDB Cluster Replication Conflict Resolution

- [Requirements](#)
- [Source Column Control](#)
- [Conflict Resolution Control](#)
- [Conflict Resolution Functions](#)
- [Conflict Resolution Exceptions Table](#)
- [Conflict Detection Status Variables](#)
- [Examples](#)

When using a replication setup involving multiple sources (including circular replication), it is possible that different sources may try to update the same row on the replica with different data. Conflict resolution in NDB Cluster Replication provides a means of resolving such conflicts by permitting a user-defined resolution column to be used to determine whether or not an update on a given source should be applied on the replica.

Some types of conflict resolution supported by NDB Cluster (`NDB$OLD()`, `NDB$MAX()`, `NDB$MAX_DELETE_WIN()`) implement this user-defined column as a “timestamp” column (although its type cannot be `TIMESTAMP`, as explained later in this section). These types of conflict resolution are always applied a row-by-row basis rather than a transactional basis. The epoch-based conflict resolution functions `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` compare the order in which epochs are replicated

(and thus these functions are transactional). Different methods can be used to compare resolution column values on the replica when conflicts occur, as explained later in this section; the method used can be set on a per-table basis.

You should also keep in mind that it is the application's responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

## Requirements

Preparations for conflict resolution must be made on both the source and the replica. These tasks are described in the following list:

- On the source writing the binary logs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the `mysqld` startup option `--ndb-log-updated-only` (described later in this section) or on a per-table basis by entries in the `mysql.ndb_replication` table (see [ndb\\_replication Table](#)).

### Note

If you are replicating tables with very large columns (such as `TEXT` or `BLOB` columns), `--ndb-log-updated-only` can also be useful for reducing the size of the binary logs and avoiding possible replication failures due to exceeding `max_allowed_packet`.

See [Section 16.4.1.19, “Replication and max\\_allowed\\_packet”](#), for more information about this issue.

- On the replica, you must determine which type of conflict resolution to apply (“latest timestamp wins”, “same timestamp wins”, “primary wins”, “primary wins, complete transaction”, or none). This is done using the `mysql.ndb_replication` system table, on a per-table basis (see [ndb\\_replication Table](#)).
- NDB Cluster also supports read conflict detection, that is, detecting conflicts between reads of a given row in one cluster and updates or deletes of the same row in another cluster. This requires exclusive read locks obtained by setting `ndb_log_exclusive_reads` equal to 1 on the replica. All rows read by a conflicting read are logged in the exceptions table. For more information, see [Read conflict detection and resolution](#).

When using the functions `NDB$OLD()`, `NDB$MAX()`, and `NDB$MAX_DELETE_WIN()` for timestamp-based conflict resolution, we often refer to the column used for determining updates as a “timestamp” column. However, the data type of this column is never `TIMESTAMP`; instead, its data type should be `INT (INTEGER)` or `BIGINT`. The “timestamp” column should also be `UNSIGNED` and `NOT NULL`.

The `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions discussed later in this section work by comparing the relative order of replication epochs applied on a primary and secondary NDB Cluster, and do not make use of timestamps.

## Source Column Control

We can see update operations in terms of “before” and “after” images—that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replica, we need to make sure that both images are written to the source's binary log. This is done with the `--ndb-log-update-as-write` option for `mysqld`, as described later in this section.

### Important

Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online;

**Important** you must either restart `mysqld`, or start a new `mysqld` instance with different logging options.

**Logging Full or Partial Rows.** For purposes of conflict resolution, there are two basic methods of logging rows, as determined by the setting of the `--ndb-log-updated-only` option for `mysqld`:

- Log complete rows (option set to `ON`)
- Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior (option set to `OFF`).

It is usually sufficient—and more efficient—to log updated columns only; however, if you need to log full rows, you can do so by setting `--ndb-log-updated-only` to `0` or `OFF`.

**Logging Changed Data as Updates.** The setting of the MySQL Server's `--ndb-log-update-as-write` option determines whether logging is performed with or without the “before” image. Because conflict resolution is done in the MySQL Server's update handler, it is necessary to control logging performed by the replication source such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows, even though these replace existing rows. This option is turned on by default; in other words, updates are treated as writes. That is, updates are by default written as `write_row` events in the binary log, rather than as `update_row` events.

To disable the option, start the source `mysqld` with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`. You must do this when replicating from NDB tables to tables using a different storage engine; see [Replication from NDB to other storage engines](#), and [Replication from NDB to a nontransactional storage engine](#), for more information.

## Conflict Resolution Control

Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the `mysql.ndb_replication` table.

`NBT_UPDATED_ONLY_MINIMAL` and `NBT_UPDATED_FULL_MINIMAL` can be used with `NDB$EPOCH()`, `NDB$EPOCH2()`, and `NDB$EPOCH_TRANS()`, because these do not require “before” values of columns which are not primary keys. Conflict resolution algorithms requiring the old values, such as `NDB$MAX()` and `NDB$OLD()`, do not work correctly with these `binlog_type` values.

## Conflict Resolution Functions

The next few paragraphs provide detailed information about the functions which can be used for conflict detection and resolution with NDB Replication.

**NDB\$OLD(column\_name).** If the value of `column_name` is the same on both the source and the replica, then the update is applied; otherwise, the update is not applied on the replica and an exception is written to the log. This is illustrated by the following pseudocode:

```
if (source_old_column_value == replica_current_column_value)
 apply_update();
else
 log_exception();
```

This function can be used for “same value wins” conflict resolution. This type of conflict resolution ensures that updates are not applied on the replica from the wrong source.

### Important

The column value from the source's “before” image is used by this function.

**NDB\$MAX(column\_name).** If the “timestamp” column value for a given row coming from the source is higher than that on the replica, it is applied; otherwise it is not applied on the replica. This is illustrated by the following pseudocode:

```
if (source_new_column_value > replica_current_column_value)
 apply_update();
```

This function can be used for “greatest timestamp wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

### Important

The column value from the source's “after” image is used by this function.

**NDB\$MAX\_DELETE\_WIN().** This is a variation on [NDB\\$MAX\(\)](#). Due to the fact that no timestamp is available for a delete operation, a delete using [NDB\\$MAX\(\)](#) is in fact processed as [NDB\\$OLD](#), but for some use cases, this is not optimal. For [NDB\\$MAX\\_DELETE\\_WIN\(\)](#), if the “timestamp” column value for a given row adding or updating an existing row coming from the source is higher than that on the replica, it is applied. However, delete operations are treated as always having the higher value. This is illustrated by the following pseudocode:

```
if ((source_new_column_value > replica_current_column_value)
 ||
 operation.type == "delete")
 apply_update();
```

This function can be used for “greatest timestamp, delete wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

### Note

As with [NDB\\$MAX\(\)](#), the column value from the source's “after” image is the value used by this function.

**NDB\$EPOCH().** The [NDB\\$EPOCH\(\)](#) function tracks the order in which replicated epochs are applied on a replica cluster relative to changes originating on the replica. This relative ordering is used to determine whether changes originating on the replica are concurrent with any changes that originate locally, and are therefore potentially in conflict.

Most of what follows in the description of [NDB\\$EPOCH\(\)](#) also applies to [NDB\\$EPOCH\\_TRANS\(\)](#). Any exceptions are noted in the text.

[NDB\\$EPOCH\(\)](#) is asymmetric, operating on one NDB Cluster in a bidirectional replication configuration (sometimes referred to as “active-active” replication). We refer here to cluster on which it operates as the primary, and the other as the secondary. The replica on the primary is responsible for detecting and handling conflicts, while the replica on the secondary is not involved in any conflict detection or handling.

When the replica on the primary detects conflicts, it injects events into its own binary log to compensate for these; this ensures that the secondary NDB Cluster eventually realigns itself with the primary and so keeps the primary and secondary from diverging. This compensation and realignment mechanism requires that the primary NDB Cluster always wins any conflicts with the secondary—that is, that the primary's changes are always used rather than those from the secondary in event of a conflict. This “primary always wins” rule has the following implications:

- Operations that change data, once committed on the primary, are fully persistent and are not undone or rolled back by conflict detection and resolution.
- Data read from the primary is fully consistent. Any changes committed on the Primary (locally or from the replica) are not reverted later.
- Operations that change data on the secondary may later be reverted if the primary determines that they are in conflict.

- Individual rows read on the secondary are self-consistent at all times, each row always reflecting either a state committed by the secondary, or one committed by the primary.
- Sets of rows read on the secondary may not necessarily be consistent at a given single point in time. For `NDB$EPOCH_TRANS()`, this is a transient state; for `NDB$EPOCH()`, it can be a persistent state.
- Assuming a period of sufficient length without any conflicts, all data on the secondary NDB Cluster (eventually) becomes consistent with the primary's data.

`NDB$EPOCH()` and `NDB$EPOCH_TRANS()` do not require any user schema modifications, or application changes to provide conflict detection. However, careful thought must be given to the schema used, and the access patterns used, to verify that the complete system behaves within specified limits.

Each of the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions can take an optional parameter; this is the number of bits to use to represent the lower 32 bits of the epoch, and should be set to no less than the value calculated as shown here:

```
CEIL(LOG2(TimeBetweenGlobalCheckpoints / TimeBetweenEpochs), 1)
```

For the default values of these configuration parameters (2000 and 100 milliseconds, respectively), this gives a value of 5 bits, so the default value (6) should be sufficient, unless other values are used for `TimeBetweenGlobalCheckpoints`, `TimeBetweenEpochs`, or both. A value that is too small can result in false positives, while one that is too large could lead to excessive wasted space in the database.

Both `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` insert entries for conflicting rows into the relevant exceptions tables, provided that these tables have been defined according to the same exceptions table schema rules as described elsewhere in this section (see `NDB$OLD(column_name)`). You must create any exceptions table before creating the data table with which it is to be used.

As with the other conflict detection functions discussed in this section, `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` are activated by including relevant entries in the `mysql.ndb_replication` table (see [ndb\\_replication Table](#)). The roles of the primary and secondary NDB Clusters in this scenario are fully determined by `mysql.ndb_replication` table entries.

Because the conflict detection algorithms employed by `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` are asymmetric, you must use different values for the `server_id` entries of the primary and secondary replicas.

A conflict between `DELETE` operations alone is not sufficient to trigger a conflict using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`, and the relative placement within epochs does not matter. (Bug #18459944)

For more information, see [Limitations on NDB\\$EPOCH\(\)](#).

**NDB\$EPOCH\_TRANS().** `NDB$EPOCH_TRANS()` extends the `NDB$EPOCH()` function. Conflicts are detected and handled in the same way using the “primary wins all” rule (see `NDB$EPOCH()`) but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. In other words, where `NDB$EPOCH()` realigns individual conflicting rows on the secondary, `NDB$EPOCH_TRANS()` realigns conflicting transactions.

In addition, any transactions which are detectably dependent on a conflicting transaction are also regarded as being in conflict, these dependencies being determined by the contents of the secondary cluster's binary log. Since the binary log contains only data modification operations (inserts, updates, and deletes), only overlapping data modifications are used to determine dependencies between transactions.

`NDB$EPOCH_TRANS()` is subject to the same conditions and limitations as `NDB$EPOCH()`, and in addition requires that Version 2 binary log row events are used (`log_bin_use_v1_row_events` equal to 0), which adds a storage overhead of 2 bytes per event in the binary log. In addition, all

transaction IDs must be recorded in the secondary's binary log (`--ndb-log-transaction-id` option), which adds a further variable overhead (up to 13 bytes per row).

See [NDB\\$EPOCH\(\)](#).

**NDB\$EPOCH2().** The [NDB\\$EPOCH2\(\)](#) function is similar to [NDB\\$EPOCH\(\)](#), except that [NDB\\$EPOCH2\(\)](#) provides for delete-delete handling with a bidirectional replication topology. In this scenario, primary and secondary roles are assigned to the two sources by setting the `ndb_slave_conflict_role` system variable to the appropriate value on each source (usually one each of `PRIMARY`, `SECONDARY`). When this is done, modifications made by the secondary are reflected by the primary back to the secondary which then conditionally applies them.

**NDB\$EPOCH2\_TRANS().** [NDB\\$EPOCH2\\_TRANS\(\)](#) extends the [NDB\\$EPOCH2\(\)](#) function. Conflicts are detected and handled in the same way, and assigning primary and secondary roles to the replicating clusters, but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. That is, [NDB\\$EPOCH2\(\)](#) realigns individual conflicting rows on the secondary, while [NDB\\$EPOCH\\_TRANS\(\)](#) realigns conflicting transactions.

Where [NDB\\$EPOCH\(\)](#) and [NDB\\$EPOCH\\_TRANS\(\)](#) use metadata that is specified per row, per last modified epoch, to determine on the primary whether an incoming replicated row change from the secondary is concurrent with a locally committed change; concurrent changes are regarded as conflicting, with subsequent exceptions table updates and realignment of the secondary. A problem arises when a row is deleted on the primary so there is no longer any last-modified epoch available to determine whether any replicated operations conflict, which means that conflicting delete operations are not detected. This can result in divergence, an example being a delete on one cluster which is concurrent with a delete and insert on the other; this why delete operations can be routed to only one cluster when using [NDB\\$EPOCH\(\)](#) and [NDB\\$EPOCH\\_TRANS\(\)](#).

[NDB\\$EPOCH2\(\)](#) bypasses the issue just described—storing information about deleted rows on the `PRIMARY`—by ignoring any delete-delete conflict, and by avoiding any potential resultant divergence as well. This is accomplished by reflecting any operation successfully applied on and replicated from the secondary back to the secondary. On its return to the secondary, it can be used to reapply an operation on the secondary which was deleted by an operation originating from the primary.

When using [NDB\\$EPOCH2\(\)](#), you should keep in mind that the secondary applies the delete from the primary, removing the new row until it is restored by a reflected operation. In theory, the subsequent insert or update on the secondary conflicts with the delete from the primary, but in this case, we choose to ignore this and allow the secondary to “win”, in the interest of preventing divergence between the clusters. In other words, after a delete, the primary does not detect conflicts, and instead adopts the secondary's following changes immediately. Because of this, the secondary's state can revisit multiple previous committed states as it progresses to a final (stable) state, and some of these may be visible.

You should also be aware that reflecting all operations from the secondary back to the primary increases the size of the primary's logbinary log, as well as demands on bandwidth, CPU usage, and disk I/O.

Application of reflected operations on the secondary depends on the state of the target row on the secondary. Whether or not reflected changes are applied on the secondary can be tracked by checking the `Ndb_conflict_reflected_op_prepare_count` and `Ndb_conflict_reflected_op_discard_count` status variables. The number of changes applied is simply the difference between these two values (note that `Ndb_conflict_reflected_op_prepare_count` is always greater than or equal to `Ndb_conflict_reflected_op_discard_count`).

Events are applied if and only if both of the following conditions are true:

- The existence of the row—that is, whether or not it exists—is in accordance with the type of event. For delete and update operations, the row must already exist. For insert operations, the row must *not* exist.

- The row was last modified by the primary. It is possible that the modification was accomplished through the execution of a reflected operation.

If both of these conditions are not met, the reflected operation is discarded by the secondary.

**Limitations on NDB\$EPOCH().** The following limitations currently apply when using `NDB$EPOCH()` to perform conflict detection:

- Conflicts are detected using NDB Cluster epoch boundaries, with granularity proportional to `TimeBetweenEpochs` (default: 100 milliseconds). The minimum conflict window is the minimum time during which concurrent updates to the same data on both clusters always report a conflict. This is always a nonzero length of time, and is roughly proportional to  $2 * (\text{latency} + \text{queueing} + \text{TimeBetweenEpochs})$ . This implies that—assuming the default for `TimeBetweenEpochs` and ignoring any latency between clusters (as well as any queuing delays)—the minimum conflict window size is approximately 200 milliseconds. This minimum window should be considered when looking at expected application “race” patterns.
- Additional storage is required for tables using the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions; from 1 to 32 bits extra space per row is required, depending on the value passed to the function.
- Conflicts between delete operations may result in divergence between the primary and secondary. When a row is deleted on both clusters concurrently, the conflict can be detected, but is not recorded, since the row is deleted. This means that further conflicts during the propagation of any subsequent realignment operations are not detected, which can lead to divergence.

Deletes should be externally serialized, or routed to one cluster only. Alternatively, a separate row should be updated transactionally with such deletes and any inserts that follow them, so that conflicts can be tracked across row deletes. This may require changes in applications.

- Only two NDB Clusters in a bidirectional “active-active” configuration are currently supported when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()` for conflict detection.
- Tables having `BLOB` or `TEXT` columns are not currently supported with `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`.

## Conflict Resolution Exceptions Table

To use the `NDB$OLD()` conflict resolution function, it is also necessary to create an exceptions table corresponding to each NDB table for which this type of conflict resolution is to be employed. This is also true when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`. The name of this table is that of the table for which conflict resolution is to be applied, with the string `$EX` appended. (For example, if the name of the original table is `mytable`, the name of the corresponding exceptions table name should be `mytable$EX`.) The syntax for creating the exceptions table is as shown here:

```
CREATE TABLE original_table$EX (
 [NDB$]server_id INT UNSIGNED,
 [NDB$]source_server_id INT UNSIGNED,
 [NDB$]source_epoch BIGINT UNSIGNED,
 [NDB$]count INT UNSIGNED,

 [NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
 'REFRESH_ROW', 'READ_ROW') NOT NULL,]
 [NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,]
 [NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,]

 original_table_pk_columns,

 [orig_table_column|orig_table_column$OLD|orig_table_column$NEW,]
 [additional_columns,]

 PRIMARY KEY([NDB$]server_id, [NDB$]source_server_id, [NDB$]source_epoch, [NDB$]count)
```

```
) ENGINE=NDB;
```

The first four columns are required. The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the `server_id`, `source_server_id`, `source_epoch`, and `count` columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

If the exceptions table uses one or more of the optional columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, or `NDB$ORIG_TRANSID` discussed later in this section, then each of the required columns must also be named using the prefix `NDB$`. If desired, you can use the `NDB$` prefix to name the required columns even if you do not define any optional columns, but in this case, all four of the required columns must be named using the prefix.

Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table. The data types for the columns duplicating the primary key columns of the original table should be the same as (or larger than) those of the original columns. A subset of the primary key columns may be used.

The exceptions table must use the `NDB` storage engine. (An example that uses `NDB$OLD()` with an exceptions table is shown later in this section.)

Additional columns may optionally be defined following the copied primary key columns, but not before any of them; any such extra columns cannot be `NOT NULL`. NDB Cluster supports three additional, predefined optional columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, and `NDB$ORIG_TRANSID`, which are described in the next few paragraphs.

**`NDB$OP_TYPE`:** This column can be used to obtain the type of operation causing the conflict. If you use this column, define it as shown here:

```
NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
 'REFRESH_ROW', 'READ_ROW') NOT NULL
```

The `WRITE_ROW`, `UPDATE_ROW`, and `DELETE_ROW` operation types represent user-initiated operations. `REFRESH_ROW` operations are operations generated by conflict resolution in compensating transactions sent back to the originating cluster from the cluster that detected the conflict. `READ_ROW` operations are user-initiated read tracking operations defined with exclusive row locks.

**`NDB$CFT_CAUSE`:** You can define an optional column `NDB$CFT_CAUSE` which provides the cause of the registered conflict. This column, if used, is defined as shown here:

```
NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL
```

`ROW_DOES_NOT_EXIST` can be reported as the cause for `UPDATE_ROW` and `WRITE_ROW` operations; `ROW_ALREADY_EXISTS` can be reported for `WRITE_ROW` events. `DATA_IN_CONFLICT` is reported when a row-based conflict function detects a conflict; `TRANS_IN_CONFLICT` is reported when a transactional conflict function rejects all of the operations belonging to a complete transaction.

**`NDB$ORIG_TRANSID`:** The `NDB$ORIG_TRANSID` column, if used, contains the ID of the originating transaction. This column should be defined as follows:

```
NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL
```

`NDB$ORIG_TRANSID` is a 64-bit value generated by `NDB`. This value can be used to correlate multiple exceptions table entries belonging to the same conflicting transaction from the same or different exceptions tables.

Additional reference columns which are not part of the original table's primary key can be named `colname$OLD` or `colname$NEW`. `colname$OLD` references old values in update and delete operations—that is, operations containing `DELETE_ROW` events. `colname$NEW` can be used to reference new values in insert and update operations—in other words, operations using `WRITE_ROW` events, `UPDATE_ROW` events, or both types of events. Where a conflicting operation does not supply a

value for a given reference column that is not a primary key, the exceptions table row contains either `NULL`, or a defined default value for that column.

### Important

The `mysql.ndb_replication` table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into `mysql.ndb_replication` before the table to be replicated is created.

## Conflict Detection Status Variables

Several status variables can be used to monitor conflict detection. You can see how many rows have been found in conflict by `NDB$EPOCH()` since this replica was last restarted from the current value of the `Ndb_conflict_fn_epoch` system status variable.

`Ndb_conflict_fn_epoch_trans` provides the number of rows that have been found directly in conflict by `NDB$EPOCH_TRANS()`. `Ndb_conflict_fn_epoch2` and `Ndb_conflict_fn_epoch2_trans` show the number of rows found in conflict by `NDB$EPOCH2()` and `NDB$EPOCH2_TRANS()`, respectively. The number of rows actually realigned, including those affected due to their membership in or dependency on the same transactions as other conflicting rows, is given by `Ndb_conflict_trans_row_reject_count`.

Another server status variable `Ndb_conflict_fn_max` provides a count of the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that `mysqld` was started.

The number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted is given by the global status variable `Ndb_conflict_fn_old`. In addition to incrementing `Ndb_conflict_fn_old`, the primary key of the row that was not used is inserted into an *exceptions table*, as explained elsewhere in this section.

See also [NDB Cluster Status Variables](#).

## Examples

The following examples assume that you have already a working NDB Cluster replication setup, as described in [Section 21.6.5, “Preparing the NDB Cluster for Replication”](#), and [Section 21.6.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”](#).

**NDB\$MAX() example.** Suppose you wish to enable “greatest timestamp wins” conflict resolution on table `test.t1`, using column `mycol` as the “timestamp”. This can be done using the following steps:

1. Make sure that you have started the source `mysqld` with `--ndb-log-update-as-write=OFF`.
2. On the source, perform this `INSERT` statement:

```
INSERT INTO mysql.ndb_replication
VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
```

Inserting a 0 into the `server_id` indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific `mysqld` only, use the actual server ID.

Inserting `NULL` into the `binlog_type` column has the same effect as inserting 0 (`NBT_DEFAULT`); the server default is used.

3. Create the `test.t1` table:

```
CREATE TABLE test.t1 (
 columns
 mycol INT UNSIGNED,
 columns
```

```
) ENGINE=NDB;
```

Now, when updates are performed on this table, conflict resolution is applied, and the version of the row having the greatest value for `mycol` is written to the replica.

### Note

Other `binlog_type` options—such as `NBT_UPDATED_ONLY_USE_UPDATE`—should be used to control logging on the source using the `ndb_replication` table rather than by using command-line options.

**NDB\$OLD() example.** Suppose an NDB table such as the one defined here is being replicated, and you wish to enable “same timestamp wins” conflict resolution for updates to this table:

```
CREATE TABLE test.t2 (
 a INT UNSIGNED NOT NULL,
 b CHAR(25) NOT NULL,
 columns,
 mycol INT UNSIGNED NOT NULL,
 columns,
 PRIMARY KEY pk (a, b)
) ENGINE=NDB;
```

The following steps are required, in the order shown:

1. First—and *prior* to creating `test.t2`—you must insert a row into the `mysql.ndb_replication` table, as shown here:

```
INSERT INTO mysql.ndb_replication
VALUES ('test', 't2', 0, NULL, 'NDB$OLD(mycol)');
```

Possible values for the `binlog_type` column are shown earlier in this section. The value '`NDB$OLD(mycol)`' should be inserted into the `conflict_fn` column.

2. Create an appropriate exceptions table for `test.t2`. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table's primary key.

```
CREATE TABLE test.t2$EX (
 server_id INT UNSIGNED,
 source_server_id INT UNSIGNED,
 source_epoch BIGINT UNSIGNED,
 count INT UNSIGNED,
 a INT UNSIGNED NOT NULL,
 b CHAR(25) NOT NULL,
 [additional_columns]
 PRIMARY KEY(server_id, source_server_id, source_epoch, count)
) ENGINE=NDB;
```

We can include additional columns for information about the type, cause, and originating transaction ID for a given conflict. We are also not required to supply matching columns for all primary key columns in the original table. This means you can create the exceptions table like this:

```
CREATE TABLE test.t2$EX (
 NDB$server_id INT UNSIGNED,
 NDB$source_server_id INT UNSIGNED,
 NDB$source_epoch BIGINT UNSIGNED,
 NDB$count INT UNSIGNED,
 a INT UNSIGNED NOT NULL,
 NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
 'REFRESH_ROW', 'READ_ROW') NOT NULL,
 NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,
 NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,
```

```
[additional_columns,]
PRIMARY KEY(NDB$server_id, NDB$source_server_id, NDB$source_epoch, NDB$count)
) ENGINE=NDB;
```

**Note**

The `NDB$` prefix is required for the four required columns since we included at least one of the columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, or `NDB$ORIG_TRANSID` in the table definition.

3. Create the table `test.t2` as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using `NDB$OLD()`. For each such table, there must be a corresponding row in `mysql.ndb_replication`, and there must be an exceptions table in the same database as the table being replicated.

**Read conflict detection and resolution.** NDB Cluster also supports tracking of read operations, which makes it possible in circular replication setups to manage conflicts between reads of a given row in one cluster and updates or deletes of the same row in another. This example uses `employee` and `department` tables to model a scenario in which an employee is moved from one department to another on the source cluster (which we refer to hereafter as cluster A) while the replica cluster (hereafter B) updates the employee count of the employee's former department in an interleaved transaction.

The data tables have been created using the following SQL statements:

```
Employee table
CREATE TABLE employee (
 id INT PRIMARY KEY,
 name VARCHAR(2000),
 dept INT NOT NULL
) ENGINE=NDB;

Department table
CREATE TABLE department (
 id INT PRIMARY KEY,
 name VARCHAR(2000),
 members INT
) ENGINE=NDB;
```

The contents of the two tables include the rows shown in the (partial) output of the following `SELECT` statements:

```
mysql> SELECT id, name, dept FROM employee;
+-----+-----+
| id | name | dept |
+-----+-----+
...
| 998 | Mike | 3 |
| 999 | Joe | 3 |
| 1000 | Mary | 3 |
...
+-----+-----+-----+
mysql> SELECT id, name, members FROM department;
+-----+-----+-----+
| id | name | members |
+-----+-----+-----+
...
| 3 | Old project | 24 |
...
+-----+-----+-----+
```

We assume that we are already using an exceptions table that includes the four required columns (and these are used for this table's primary key), the optional columns for operation type and cause, and the original table's primary key column, created using the SQL statement shown here:

```

CREATE TABLE employee$EX (
 NDB$server_id INT UNSIGNED,
 NDB$source_server_id INT UNSIGNED,
 NDB$source_epoch BIGINT UNSIGNED,
 NDB$count INT UNSIGNED,

 NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
 'REFRESH_ROW', 'READ_ROW') NOT NULL,
 NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST',
 'ROW_ALREADY_EXISTS',
 'DATA_IN_CONFLICT',
 'TRANS_IN_CONFLICT') NOT NULL,

 id INT NOT NULL,
 PRIMARY KEY(NDB$server_id, NDB$source_server_id, NDB$source_epoch, NDB$count)
) ENGINE=NDB;

```

Suppose there occur the two simultaneous transactions on the two clusters. On cluster *A*, we create a new department, then move employee number 999 into that department, using the following SQL statements:

```

BEGIN;
 INSERT INTO department VALUES (4, "New project", 1);
 UPDATE employee SET dept = 4 WHERE id = 999;
COMMIT;

```

At the same time, on cluster *B*, another transaction reads from `employee`, as shown here:

```

BEGIN;
 SELECT name FROM employee WHERE id = 999;
 UPDATE department SET members = members - 1 WHERE id = 3;
commit;

```

The conflicting transactions are not normally detected by the conflict resolution mechanism, since the conflict is between a read (`SELECT`) and an update operation. You can circumvent this issue by executing `SET ndb_log_exclusive_reads = 1` on the replica cluster. Acquiring exclusive read locks in this way causes any rows read on the source to be flagged as needing conflict resolution on the replica cluster. If we enable exclusive reads in this way prior to the logging of these transactions, the read on cluster *B* is tracked and sent to cluster *A* for resolution; the conflict on the `employee` row is subsequently detected and the transaction on cluster *B* is aborted.

The conflict is registered in the exceptions table (on cluster *A*) as a `READ_ROW` operation (see [Conflict Resolution Exceptions Table](#), for a description of operation types), as shown here:

```

mysql> SELECT id, NDBOP_TYPE, NDBCFT_CAUSE FROM employee$EX;
+-----+-----+-----+
| id | NDB$OP_TYPE | NDB$CFT_CAUSE |
+-----+-----+-----+
...
| 999 | READ_ROW | TRANS_IN_CONFLICT |
+-----+-----+-----+

```

Any existing rows found in the read operation are flagged. This means that multiple rows resulting from the same conflict may be logged in the exception table, as shown by examining the effects a conflict between an update on cluster *A* and a read of multiple rows on cluster *B* from the same table in simultaneous transactions. The transaction executed on cluster *A* is shown here:

```

BEGIN;
 INSERT INTO department VALUES (4, "New project", 0);
 UPDATE employee SET dept = 4 WHERE dept = 3;
 SELECT COUNT(*) INTO @count FROM employee WHERE dept = 4;
 UPDATE department SET members = @count WHERE id = 4;
COMMIT;

```

Concurrently a transaction containing the statements shown here runs on cluster *B*:

```
SET ndb_log_exclusive_reads = 1; # Must be set if not already enabled
...
BEGIN;
 SELECT COUNT(*) INTO @count FROM employee WHERE dept = 3 FOR UPDATE;
 UPDATE department SET members = @count WHERE id = 3;
COMMIT;
```

In this case, all three rows matching the `WHERE` condition in the second transaction's `SELECT` are read, and are thus flagged in the exceptions table, as shown here:

```
mysql> SELECT id, NDBOP_TYPE, NDBCFT_CAUSE FROM employee$EX;
+-----+-----+-----+
| id | NDB$OP_TYPE | NDB$CFT_CAUSE |
+-----+-----+-----+
...
| 998 | READ_ROW | TRANS_IN_CONFLICT |
| 999 | READ_ROW | TRANS_IN_CONFLICT |
| 1000 | READ_ROW | TRANS_IN_CONFLICT |
...
+-----+-----+-----+
```

Read tracking is performed on the basis of existing rows only. A read based on a given condition track conflicts only of any rows that are *found* and not of any rows that are inserted in an interleaved transaction. This is similar to how exclusive row locking is performed in a single instance of NDB Cluster.

## 21.7 NDB Cluster Release Notes

Changes in NDB Cluster releases are documented separately from this reference manual; you can find release notes for the changes in each NDB Cluster 7.5 release at [NDB 7.5 Release Notes](#), and for each NDB Cluster 7.6 release at [NDB 7.6 Release Notes](#).

You can obtain release notes for older versions of NDB Cluster from [NDB Cluster Release Notes](#).

This chapter discusses MySQL's implementation of *user-defined partitioning*.

### Note

As of MySQL 5.7.17, the generic partitioning handler in the MySQL server is deprecated, and is removed in MySQL 8.0, when the storage engine used for a given table is expected to provide its own (“native”) partitioning handler. Currently, only the `InnoDB` and `NDB` storage engines do this.

Use of tables with nonnative partitioning results in an `ER_WARN_DEPRECATED_SYNTAX` warning. In MySQL 5.7.17 through 5.7.20, the server automatically performs a check at startup to identify tables that use nonnative partitioning; for any that are found, the server writes a message to its error log. To disable this check, use the `--disable-partition-engine-check` option. In MySQL 5.7.21 and later, this check is *not* performed; in these versions, you must start the server with `--disable-partition-engine-check=false`, if you wish for the server to check for tables using the generic partitioning handler (Bug #85830, Bug #25846957).

To prepare for migration to MySQL 8.0, any table with nonnative partitioning should be changed to use an engine that provides native partitioning, or be made nonpartitioned. For example, to change a table to `InnoDB`, execute this statement:

```
ALTER TABLE table_name ENGINE = INNODB;
```

You can determine whether your MySQL Server supports partitioning by checking the output of the `SHOW PLUGINS` statement, like this:

```
mysql> SHOW PLUGINS;
+-----+-----+-----+-----+
```

| Name             | Status        | Type                  | Library     | License    |
|------------------|---------------|-----------------------|-------------|------------|
| binlog           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| <b>partition</b> | <b>ACTIVE</b> | <b>STORAGE ENGINE</b> | <b>NULL</b> | <b>GPL</b> |
| ARCHIVE          | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| BLACKHOLE        | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| CSV              | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| FEDERATED        | DISABLED      | STORAGE ENGINE        | NULL        | GPL        |
| MEMORY           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| InnoDB           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| MRG_MYISAM       | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| MyISAM           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| ndbcluster       | DISABLED      | STORAGE ENGINE        | NULL        | GPL        |

11 rows in set (0.00 sec)

You can also check the `INFORMATION_SCHEMA.PLUGINS` table with a query similar to this one:

```
mysql> SELECT
 -> PLUGIN_NAME as Name,
 -> PLUGIN_VERSION as Version,
 -> PLUGIN_STATUS as Status
 -> FROM INFORMATION_SCHEMA.PLUGINS
 -> WHERE PLUGIN_TYPE='STORAGE ENGINE';
+-----+-----+-----+
| Name | Version | Status |
+-----+-----+-----+
| binlog | 1.0 | ACTIVE |
| CSV | 1.0 | ACTIVE |
| MEMORY | 1.0 | ACTIVE |
| MRG_MYISAM| 1.0 | ACTIVE |
| MyISAM | 1.0 | ACTIVE |
| PERFORMANCE_SCHEMA| 0.1 | ACTIVE |
| BLACKHOLE | 1.0 | ACTIVE |
| ARCHIVE | 3.0 | ACTIVE |
| InnoDB | 5.7 | ACTIVE |
| partition | 1.0 | ACTIVE |
+-----+-----+-----+
10 rows in set (0.00 sec)
```

In either case, if you do not see the `partition` plugin listed with the value `ACTIVE` for the `Status` column in the output (shown in bold text in each of the examples just given), then your version of MySQL was not built with partitioning support.

MySQL 5.7 Community binaries provided by Oracle include partitioning support. For information about partitioning support offered in MySQL Enterprise Edition binaries, see [Chapter 28, MySQL Enterprise Edition](#).

To enable partitioning if you are compiling MySQL 5.7 from source, the build must be configured with the `-DWITH_PARTITION_STORAGE_ENGINE` option. For more information, see [Section 2.9, “Installing MySQL from Source”](#).

If your MySQL binary is built with partitioning support, nothing further needs to be done to enable it (for example, no special entries are required in your `my.cnf` file).

If you want to disable partitioning support, you can start the MySQL Server with the `--skip-partition` option. When partitioning support is disabled, you can see any existing partitioned tables and drop them (although doing this is not advised), but you cannot otherwise manipulate them or access their data.

See [Section 22.1, “Overview of Partitioning in MySQL”](#), for an introduction to partitioning and partitioning concepts.

MySQL supports several types of partitioning as well as subpartitioning; see [Section 22.2, “Partitioning Types”](#), and [Section 22.6, “Subpartitioning”](#).

[Section 22.3, “Partition Management”](#), covers methods of adding, removing, and altering partitions in existing partitioned tables.

Section 22.3.4, “Maintenance of Partitions”, discusses table maintenance commands for use with partitioned tables.

The `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See Section 24.3.16, “The `INFORMATION_SCHEMA PARTITIONS` Table”, for more information; for some examples of queries against this table, see Section 22.2.7, “How MySQL Partitioning Handles NULL”.

For known issues with partitioning in MySQL 5.7, see Section 22.6, “Restrictions and Limitations on Partitioning”.

You may also find the following resources to be useful when working with partitioned tables.

**Additional Resources.** Other sources of information about user-defined partitioning in MySQL include the following:

- [MySQL Partitioning Forum](#)

This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- [Mikael Ronström's Blog](#)

MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and NDB Cluster.

- [PlanetMySQL](#)

A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.7 binaries are available from <https://dev.mysql.com/downloads/mysql/5.7.html>.

However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our GitHub repository. To enable partitioning, the build must be configured with the `-DWITH_PARTITION_STORAGE_ENGINE` option. For more information about building MySQL, see Section 2.9, “Installing MySQL from Source”. If you have problems compiling a partitioning-enabled MySQL 5.7 build, check the [MySQL Partitioning Forum](#) and ask for assistance there if you do not find a solution to your problem already posted.

## 22.1 Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.7.

For information on partitioning restrictions and feature limitations, see Section 22.6, “Restrictions and Limitations on Partitioning”.

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the `InnoDB` storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see Section 8.12.3, “Using Symbolic Links”, for an explanation of how this is done).

*Partitioning* takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the

modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value, a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of `RANGE`, `LIST`, and `[LINEAR] HASH` partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either `NULL` or an integer `intval` such that

```
-MAXVALUE <= intval <= MAXVALUE
```

(`MAXVALUE` is used to represent the least upper bound for the type of integer in question. `-MAXVALUE` represents the greatest lower bound.)

For `[LINEAR] KEY`, `RANGE COLUMNS`, and `LIST COLUMNS` partitioning, the partitioning expression consists of a list of one or more columns.

For `[LINEAR] KEY` partitioning, the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see [Section 22.2, “Partitioning Types”](#), as well as [Section 13.1.18, “CREATE TABLE Statement”](#), which provides partitioning syntax descriptions and additional examples. For information about restrictions on partitioning functions, see [Section 22.6.3, “Partitioning Limitations Relating to Functions”](#).

This is known as *horizontal partitioning*—that is, different rows of a table may be assigned to different physical partitions. MySQL 5.7 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are no plans at this time to introduce vertical partitioning into MySQL.

For information about determining whether your MySQL Server binary supports user-defined partitioning, see [Chapter 22, Partitioning](#).

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.7, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use `MyISAM` for one partition and `InnoDB` for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

MySQL partitioning cannot be used with the `MERGE`, `CSV`, or `FEDERATED` storage engines.

Partitioning by `KEY` or `LINEAR KEY` is possible with `NDB`, but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an `NDB` table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table's partitioning expression must be part of the primary key. However, if no columns are listed in the `PARTITION BY KEY` or `PARTITION BY LINEAR KEY` clause of the `CREATE TABLE` or `ALTER TABLE` statement used to create or modify a user-partitioned `NDB` table, then the table is not required to have an explicit primary key. For more information, see [Section 21.1.7.1, “Noncompliance with SQL Syntax in NDB Cluster”](#).

To employ a particular storage engine for a partitioned table, it is necessary only to use the `[STORAGE] ENGINE` option just as you would for a nonpartitioned table. However, you should keep in mind that `[STORAGE] ENGINE` (and other table options) need to be listed *before* any partitioning options are used in a `CREATE TABLE` statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the `InnoDB` storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
 ENGINE=INNODB
 PARTITION BY HASH(MONTH(tr_date))
 PARTITIONS 6;
```

Each `PARTITION` clause can include a `[STORAGE] ENGINE` option, but in MySQL 5.7 this has no effect.

### Important

Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or vice versa, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

`DATA DIRECTORY` and `INDEX DIRECTORY` are not supported for individual partitions or subpartitions of `MyISAM` tables on Windows.

Only the `DATA DIRECTORY` option is supported for individual partitions and subpartitions of `InnoDB` tables.

All columns used in the table's partitioning expression must be part of every unique key that the table may have, including any primary key. This means that a table such as this one, created by the following SQL statement, cannot be partitioned:

```
CREATE TABLE tnp (
 id INT NOT NULL AUTO_INCREMENT,
 ref BIGINT NOT NULL,
 name VARCHAR(255),
 PRIMARY KEY pk (id),
 UNIQUE KEY uk (name)
);
```

Because the keys `pk` and `uk` have no columns in common, there are no columns available for use in a partitioning expression. Possible workarounds in this situation include adding the `name` column to the table's primary key, adding the `id` column to `uk`, or simply removing the unique key altogether. See [Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#), for more information.

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. See [Section 22.3, “Partition Management”](#), for more information on these options.

The `MAX_ROWS` option can also be useful for creating NDB Cluster tables with extra partitions, thus allowing for greater storage of hash indexes. See the documentation for the `DataMemory` data node configuration parameter, as well as [Section 21.1.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#), for more information.

Some advantages of partitioning are listed here:

- Partitioning makes it possible to store more data in one table than can be held on a single disk or file system partition.
- Data that loses its usefulness can often be easily removed from a partitioned table by dropping the partition (or partitions) containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding one or more new partitions for storing specifically that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, which automatically excludes any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been often used when the partitioning scheme was first set up. This ability to exclude non-matching partitions (and thus any rows they contain) is often referred to as *partition pruning*. For more information, see [Section 22.4, “Partition Pruning”](#).

In addition, MySQL supports explicit partition selection for queries. For example, `SELECT * FROM t PARTITION (p0,p1) WHERE c < 5` selects only those rows in partitions `p0` and `p1` that match the `WHERE` condition. In this case, MySQL does not check any other partitions of table `t`; this can greatly speed up queries when you already know which partition or partitions you wish to examine. Partition selection is also supported for the data modification statements `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and `LOAD DATA`, `LOAD XML`. See the descriptions of these statements for more information and examples.

## 22.2 Partitioning Types

This section discusses the types of partitioning which are available in MySQL 5.7. These include the types listed here:

- **RANGE partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See [Section 22.2.1, “RANGE Partitioning”](#). For information about an extension to this type, `RANGE COLUMNS`, see [Section 22.2.3.1, “RANGE COLUMNS partitioning”](#).
- **LIST partitioning.** Similar to partitioning by `RANGE`, except that the partition is selected based on columns matching one of a set of discrete values. See [Section 22.2.2, “LIST Partitioning”](#). For information about an extension to this type, `LIST COLUMNS`, see [Section 22.2.3.2, “LIST COLUMNS partitioning”](#).
- **HASH partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, `LINEAR HASH`, is also available. See [Section 22.2.4, “HASH Partitioning”](#).
- **KEY partitioning.** This type of partitioning is similar to partitioning by `HASH`, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, `LINEAR KEY`, is also available. See [Section 22.2.5, “KEY Partitioning”](#).

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.7. However, it is not difficult in MySQL to create partitioning schemes based on `DATE`, `TIME`, or `DATETIME` columns, or based on expressions making use of such columns.

When partitioning by `KEY` or `LINEAR KEY`, you can use a `DATE`, `TIME`, or `DATETIME` column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
 firstname VARCHAR(25) NOT NULL,
 lastname VARCHAR(25) NOT NULL,
 username VARCHAR(16) NOT NULL,
 email VARCHAR(35),
 joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

In MySQL 5.7, it is also possible to use a `DATE` or `DATETIME` column as the partitioning column using `RANGE COLUMNS` and `LIST COLUMNS` partitioning.

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or `NULL`. If you wish to use date-based partitioning by `RANGE`, `LIST`, `HASH`, or `LINEAR HASH`, you can simply employ a function that operates on a `DATE`, `TIME`, or `DATETIME` column and returns such a value, as shown here:

```

CREATE TABLE members (
 firstname VARCHAR(25) NOT NULL,
 lastname VARCHAR(25) NOT NULL,
 username VARCHAR(16) NOT NULL,
 email VARCHAR(35),
 joined DATE NOT NULL
)
PARTITION BY RANGE(YEAR(joined)) (
 PARTITION p0 VALUES LESS THAN (1960),
 PARTITION p1 VALUES LESS THAN (1970),
 PARTITION p2 VALUES LESS THAN (1980),
 PARTITION p3 VALUES LESS THAN (1990),
 PARTITION p4 VALUES LESS THAN MAXVALUE
);

```

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- [Section 22.2.1, “RANGE Partitioning”](#)
- [Section 22.2.4, “HASH Partitioning”](#)
- [Section 22.2.4.1, “LINEAR HASH Partitioning”](#)

For more complex examples of date-based partitioning, see the following sections:

- [Section 22.4, “Partition Pruning”](#)
- [Section 22.2.6, “Subpartitioning”](#)

MySQL partitioning is optimized for use with the `TO_DAYS()`, `YEAR()`, and `TO_SECONDS()` functions. However, you can use other date and time functions that return an integer or `NULL`, such as `WEEKDAY()`, `DAYOFYEAR()`, or `MONTH()`. See [Section 12.7, “Date and Time Functions”](#), for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with `0`. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered `0`, `1`, `2`, and `3`. For the `RANGE` and `LIST` partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For `HASH` partitioning, the user-supplied expression must evaluate to an integer value greater than `0`. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```

mysql> CREATE TABLE t2 (val INT)
-> PARTITION BY LIST(val)(
-> PARTITION mypart VALUES IN (1,3,5),
-> PARTITION MyPart VALUES IN (2,4,6)
->);
ERROR 1488 (HY000): Duplicate partition name mypart

```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. Decimal fractions are not permitted.

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in [Section 13.1.18, “CREATE TABLE Statement”](#).

## 22.2.1 RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT NOT NULL,
 store_id INT NOT NULL
);
```

### Note

The `employees` table used here has no primary or unique keys. While the examples work as shown for purposes of the present discussion, you should keep in mind that tables are extremely likely in practice to have primary keys, unique keys, or both, and that allowable choices for partitioning columns depend on the columns used for these keys, if any are present. For a discussion of these issues, see [Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#).

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT NOT NULL,
 store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
 PARTITION p0 VALUES LESS THAN (6),
 PARTITION p1 VALUES LESS THAN (11),
 PARTITION p2 VALUES LESS THAN (16),
 PARTITION p3 VALUES LESS THAN (21)
);
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Note that each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a series of `if ... elseif ...` statements in C or Java in this regard.

It is easy to determine that a new row containing the data `(72, 'Mitchell', 'Wilson', '1998-06-25', NULL, 13)` is inserted into partition `p2`, but what happens when your chain adds a 21<sup>st</sup> store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than the highest value explicitly named:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT NOT NULL,
```

```

 store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
 PARTITION p0 VALUES LESS THAN (6),
 PARTITION p1 VALUES LESS THAN (11),
 PARTITION p2 VALUES LESS THAN (16),
 PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

### Note

Another way to avoid an error when no matching value is found is to use the `IGNORE` keyword as part of the `INSERT` statement. For an example, see [Section 22.2.2, “LIST Partitioning”](#). Also see [Section 13.2.5, “INSERT Statement”](#), for general information about `IGNORE`.

`MAXVALUE` represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a *least upper bound*). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see [Section 22.3, “Partition Management”](#), for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of `job_code` column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

```

CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT NOT NULL,
 store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
 PARTITION p0 VALUES LESS THAN (100),
 PARTITION p1 VALUES LESS THAN (1000),
 PARTITION p2 VALUES LESS THAN (10000)
);

```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in `VALUES LESS THAN` clauses. However, MySQL must be able to evaluate the expression's return value as part of a `LESS THAN (<)` comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of `YEAR(separated)`. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```

CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY RANGE (YEAR(separated)) (
 PARTITION p0 VALUES LESS THAN (1991),
 PARTITION p1 VALUES LESS THAN (1996),

```

## RANGE Partitioning

```
PARTITION p2 VALUES LESS THAN (2001),
PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

It is also possible to partition a table by `RANGE`, based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP()` function, as shown in this example:

```
CREATE TABLE quarterly_report_status (
 report_id INT NOT NULL,
 report_status VARCHAR(20) NOT NULL,
 report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE (UNIX_TIMESTAMP(report_updated)) (
 PARTITION p0 VALUES LESS THAN (UNIX_TIMESTAMP('2008-01-01 00:00:00')),
 PARTITION p1 VALUES LESS THAN (UNIX_TIMESTAMP('2008-04-01 00:00:00')),
 PARTITION p2 VALUES LESS THAN (UNIX_TIMESTAMP('2008-07-01 00:00:00')),
 PARTITION p3 VALUES LESS THAN (UNIX_TIMESTAMP('2008-10-01 00:00:00')),
 PARTITION p4 VALUES LESS THAN (UNIX_TIMESTAMP('2009-01-01 00:00:00')),
 PARTITION p5 VALUES LESS THAN (UNIX_TIMESTAMP('2009-04-01 00:00:00')),
 PARTITION p6 VALUES LESS THAN (UNIX_TIMESTAMP('2009-07-01 00:00:00')),
 PARTITION p7 VALUES LESS THAN (UNIX_TIMESTAMP('2009-10-01 00:00:00')),
 PARTITION p8 VALUES LESS THAN (UNIX_TIMESTAMP('2010-01-01 00:00:00')),
 PARTITION p9 VALUES LESS THAN (MAXVALUE)
);
```

Any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

Range partitioning is particularly useful when one or more of the following conditions is true:

- You want or need to delete “old” data. If you are using the partitioning scheme shown previously for the `employees` table, you can simply use `ALTER TABLE employees DROP PARTITION p0`; to delete all rows relating to employees who stopped working for the firm prior to 1991. (See [Section 13.1.8, “ALTER TABLE Statement”](#), and [Section 22.3, “Partition Management”](#), for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990`.
- You want to use a column containing date or time values, or containing values arising from some other series.
- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;`, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See [Section 22.4, “Partition Pruning”](#), for more information about how this is accomplished.

A variant on this type of partitioning is `RANGE COLUMNS` partitioning. Partitioning by `RANGE COLUMNS` makes it possible to employ multiple columns for defining partitioning ranges that apply both to placement of rows in partitions and for determining the inclusion or exclusion of specific partitions when performing partition pruning. See [Section 22.2.3.1, “RANGE COLUMNS partitioning”](#), for more information.

**Partitioning schemes based on time intervals.** If you wish to implement a partitioning scheme based on ranges or intervals of time in MySQL 5.7, you have two options:

1. Partition the table by `RANGE`, and for the partitioning expression, employ a function operating on a `DATE`, `TIME`, or `DATETIME` column and returning an integer value, as shown here:

```
CREATE TABLE members (
 firstname VARCHAR(25) NOT NULL,
 lastname VARCHAR(25) NOT NULL,
```

```

username VARCHAR(16) NOT NULL,
email VARCHAR(35),
joined DATE NOT NULL
)
PARTITION BY RANGE(YEAR(joined)) (
PARTITION p0 VALUES LESS THAN (1960),
PARTITION p1 VALUES LESS THAN (1970),
PARTITION p2 VALUES LESS THAN (1980),
PARTITION p3 VALUES LESS THAN (1990),
PARTITION p4 VALUES LESS THAN MAXVALUE
);

```

In MySQL 5.7, it is also possible to partition a table by [RANGE](#) based on the value of a [TIMESTAMP](#) column, using the [UNIX\\_TIMESTAMP\(\)](#) function, as shown in this example:

```

CREATE TABLE quarterly_report_status (
report_id INT NOT NULL,
report_status VARCHAR(20) NOT NULL,
report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE (UNIX_TIMESTAMP(report_updated)) (
PARTITION p0 VALUES LESS THAN (UNIX_TIMESTAMP('2008-01-01 00:00:00')),
PARTITION p1 VALUES LESS THAN (UNIX_TIMESTAMP('2008-04-01 00:00:00')),
PARTITION p2 VALUES LESS THAN (UNIX_TIMESTAMP('2008-07-01 00:00:00')),
PARTITION p3 VALUES LESS THAN (UNIX_TIMESTAMP('2008-10-01 00:00:00')),
PARTITION p4 VALUES LESS THAN (UNIX_TIMESTAMP('2009-01-01 00:00:00')),
PARTITION p5 VALUES LESS THAN (UNIX_TIMESTAMP('2009-04-01 00:00:00')),
PARTITION p6 VALUES LESS THAN (UNIX_TIMESTAMP('2009-07-01 00:00:00')),
PARTITION p7 VALUES LESS THAN (UNIX_TIMESTAMP('2009-10-01 00:00:00')),
PARTITION p8 VALUES LESS THAN (UNIX_TIMESTAMP('2010-01-01 00:00:00')),
PARTITION p9 VALUES LESS THAN (MAXVALUE)
);

```

In MySQL 5.7, any other expressions involving [TIMESTAMP](#) values are not permitted. (See Bug #42849.)

#### Note

It is also possible in MySQL 5.7 to use [UNIX\\_TIMESTAMP\(timestamp\\_column\)](#) as a partitioning expression for tables that are partitioned by [LIST](#). However, it is usually not practical to do so.

- Partition the table by [RANGE COLUMNS](#), using a [DATE](#) or [DATETIME](#) column as the partitioning column. For example, the `members` table could be defined using the `joined` column directly, as shown here:

```

CREATE TABLE members (
firstname VARCHAR(25) NOT NULL,
lastname VARCHAR(25) NOT NULL,
username VARCHAR(16) NOT NULL,
email VARCHAR(35),
joined DATE NOT NULL
)
PARTITION BY RANGE COLUMNS(joined) (
PARTITION p0 VALUES LESS THAN ('1960-01-01'),
PARTITION p1 VALUES LESS THAN ('1970-01-01'),
PARTITION p2 VALUES LESS THAN ('1980-01-01'),
PARTITION p3 VALUES LESS THAN ('1990-01-01'),
PARTITION p4 VALUES LESS THAN MAXVALUE
);

```

#### Note

The use of partitioning columns employing date or time types other than [DATE](#) or [DATETIME](#) is not supported with [RANGE COLUMNS](#).

## 22.2.2 LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by [RANGE](#), each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where `expr` is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where `value_list` is a comma-separated list of integers.

### Note

In MySQL 5.7, it is possible to match against only a list of integers (and possibly `NULL`—see [Section 22.2.7, “How MySQL Partitioning Handles NULL”](#)) when partitioning by `LIST`.

However, other column types may be used in value lists when employing `LIST COLUMN` partitioning, which is described later in this section.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see [Section 13.1.18, “CREATE TABLE Statement”](#).

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
);
```

(This is the same table used as a basis for the examples in [Section 22.2.1, “RANGE Partitioning”](#).)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

| Region  | Store ID Numbers     |
|---------|----------------------|
| North   | 3, 5, 6, 9, 17       |
| East    | 1, 2, 10, 11, 19, 20 |
| West    | 4, 12, 13, 14, 18    |
| Central | 7, 8, 15, 16         |

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY LIST(store_id) (
 PARTITION pNorth VALUES IN (3,5,6,9,17),
 PARTITION pEast VALUES IN (1,2,10,11,19,20),
 PARTITION pWest VALUES IN (4,12,13,14,18),
 PARTITION pCentral VALUES IN (7,8,15,16)
```

```
);
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. In MySQL 5.7, all rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees TRUNCATE PARTITION pWest`, which can be executed much more efficiently than the equivalent `DELETE` statement `DELETE FROM employees WHERE store_id IN (4,12,13,14,18)`. (Using `ALTER TABLE employees DROP PARTITION pWest` would also delete all of these rows, but would also remove the partition `pWest` from the definition of the table; you would need to use an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme.)

As with `RANGE` partitioning, it is possible to combine `LIST` partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See [Section 22.2.6, “Subpartitioning”](#).

Unlike the case with `RANGE` partitioning, there is no “catch-all” such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 (
 -> c1 INT,
 -> c2 INT
 ->)
 -> PARTITION BY LIST(c1) (
 -> PARTITION p0 VALUES IN (1, 4, 7),
 -> PARTITION p1 VALUES IN (2, 5, 8)
 ->);
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): Table has no partition for value 3
```

When inserting multiple rows using a single `INSERT` statement the behavior depends on whether the table uses a transactional storage engine. For an `InnoDB` table, the statement is considered a single transaction, so the presence of any unmatched values causes the statement to fail completely, and no rows are inserted. For a table using a nontransactional storage engine such as `MyISAM`, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not.

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values are inserted, and no errors are reported:

```
mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5 Duplicates: 2 Warnings: 0

mysql> SELECT * FROM h2;
+---+---+
| c1 | c2 |
+---+---+
| 7 | 5 |
| 1 | 9 |
| 2 | 5 |
+---+---+
3 rows in set (0.00 sec)
```

MySQL 5.7 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables you to use columns of types other than integer types for partitioning columns, as well as to use

multiple columns as partitioning keys. For more information, see [Section 22.2.3.2, “LIST COLUMNS partitioning”](#).

## 22.2.3 COLUMNS Partitioning

The next two sections discuss *COLUMNS partitioning*, which are variants on *RANGE* and *LIST* partitioning. *COLUMNS* partitioning enables the use of multiple columns in partitioning keys. All of these columns are taken into account both for the purpose of placing rows in partitions and for the determination of which partitions are to be checked for matching rows in partition pruning.

In addition, both *RANGE COLUMNS* partitioning and *LIST COLUMNS* partitioning support the use of non-integer columns for defining value ranges or list members. The permitted data types are shown in the following list:

- All integer types: `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT` (`INTEGER`), and `BIGINT`. (This is the same as with partitioning by *RANGE* and *LIST*.)

Other numeric data types (such as `DECIMAL` or `FLOAT`) are not supported as partitioning columns.

- `DATE` and `DATETIME`.

Columns using other data types relating to dates or times are not supported as partitioning columns.

- The following string types: `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY`.

`TEXT` and `BLOB` columns are not supported as partitioning columns.

The discussions of *RANGE COLUMNS* and *LIST COLUMNS* partitioning in the next two sections assume that you are already familiar with partitioning based on ranges and lists as supported in MySQL 5.1 and later; for more information about these, see [Section 22.2.1, “RANGE Partitioning”](#), and [Section 22.2.2, “LIST Partitioning”](#), respectively.

### 22.2.3.1 RANGE COLUMNS partitioning

Range columns partitioning is similar to range partitioning, but enables you to define partitions using ranges based on multiple column values. In addition, you can define the ranges using columns of types other than integer types.

*RANGE COLUMNS* partitioning differs significantly from *RANGE* partitioning in the following ways:

- *RANGE COLUMNS* does not accept expressions, only names of columns.
- *RANGE COLUMNS* accepts a list of one or more columns.

*RANGE COLUMNS* partitions are based on comparisons between *tuples* (lists of column values) rather than comparisons between scalar values. Placement of rows in *RANGE COLUMNS* partitions is also based on comparisons between tuples; this is discussed further later in this section.

- *RANGE COLUMNS* partitioning columns are not restricted to integer columns; string, `DATE` and `DATETIME` columns can also be used as partitioning columns. (See [Section 22.2.3, “COLUMNS Partitioning”](#), for details.)

The basic syntax for creating a table partitioned by *RANGE COLUMNS* is shown here:

```
CREATE TABLE table_name
PARTITIONED BY RANGE COLUMNS(column_list) (
 PARTITION partition_name VALUES LESS THAN (value_list)[,

 PARTITION partition_name VALUES LESS THAN (value_list)][[,

 ...]
)

column_list:
 column_name[, column_name][, ...]
```

```
value_list:
 value[, value][, ...]
```

**Note**

Not all `CREATE TABLE` options that can be used when creating partitioned tables are shown here. For complete information, see [Section 13.1.18, "CREATE TABLE Statement"](#).

In the syntax just shown, `column_list` is a list of one or more columns (sometimes called a *partitioning column list*), and `value_list` is a list of values (that is, it is a *partition definition value list*). A `value_list` must be supplied for each partition definition, and each `value_list` must have the same number of values as the `column_list` has columns. Generally speaking, if you use `N` columns in the `COLUMNS` clause, then each `VALUES LESS THAN` clause must also be supplied with a list of `N` values.

The elements in the partitioning column list and in the value list defining each partition must occur in the same order. In addition, each element in the value list must be of the same data type as the corresponding element in the column list. However, the order of the column names in the partitioning column list and the value lists does not have to be the same as the order of the table column definitions in the main part of the `CREATE TABLE` statement. As with table partitioned by `RANGE`, you can use `MAXVALUE` to represent a value such that any legal value inserted into a given column is always less than this value. Here is an example of a `CREATE TABLE` statement that helps to illustrate all of these points:

```
mysql> CREATE TABLE rcx (
 -> a INT,
 -> b INT,
 -> c CHAR(3),
 -> d INT
 ->)
 -> PARTITION BY RANGE COLUMNS(a,d,c) (
 -> PARTITION p0 VALUES LESS THAN (5,10,'ggg'),
 -> PARTITION p1 VALUES LESS THAN (10,20,'mmm'),
 -> PARTITION p2 VALUES LESS THAN (15,30,'sss'),
 -> PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
 ->);
Query OK, 0 rows affected (0.15 sec)
```

Table `rcx` contains the columns `a`, `b`, `c`, `d`. The partitioning column list supplied to the `COLUMNS` clause uses 3 of these columns, in the order `a`, `d`, `c`. Each value list used to define a partition contains 3 values in the same order; that is, each value list tuple has the form (`INT`, `INT`, `CHAR(3)`), which corresponds to the data types used by columns `a`, `d`, and `c` (in that order).

Placement of rows into partitions is determined by comparing the tuple from a row to be inserted that matches the column list in the `COLUMNS` clause with the tuples used in the `VALUES LESS THAN` clauses to define partitions of the table. Because we are comparing tuples (that is, lists or sets of values) rather than scalar values, the semantics of `VALUES LESS THAN` as used with `RANGE COLUMNS` partitions differs somewhat from the case with simple `RANGE` partitions. In `RANGE` partitioning, a row generating an expression value that is equal to a limiting value in a `VALUES LESS THAN` is never placed in the corresponding partition; however, when using `RANGE COLUMNS` partitioning, it is sometimes possible for a row whose partitioning column list's first element is equal in value to the that of the first element in a `VALUES LESS THAN` value list to be placed in the corresponding partition.

Consider the `RANGE` partitioned table created by this statement:

```
CREATE TABLE r1 (
 a INT,
 b INT
)
PARTITION BY RANGE (a) (
 PARTITION p0 VALUES LESS THAN (5),
 PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert 3 rows into this table such that the column value for `a` is 5 for each row, all 3 rows are stored in partition `p1` because the `a` column value is in each case not less than 5, as we can see by executing the proper query against the `INFORMATION_SCHEMA.PARTITIONS` table:

```
mysql> INSERT INTO r1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
 -> FROM INFORMATION_SCHEMA.PARTITIONS
 -> WHERE TABLE_NAME = 'r1';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0 | 0 |
| p1 | 3 |
+-----+-----+
2 rows in set (0.00 sec)
```

Now consider a similar table `rcl` that uses `RANGE COLUMNS` partitioning with both columns `a` and `b` referenced in the `COLUMNS` clause, created as shown here:

```
CREATE TABLE rcl (
 a INT,
 b INT
)
PARTITION BY RANGE COLUMNS(a, b) (
 PARTITION p0 VALUES LESS THAN (5, 12),
 PARTITION p3 VALUES LESS THAN (MAXVALUE, MAXVALUE)
);
```

If we insert exactly the same rows into `rcl` as we just inserted into `r1`, the distribution of the rows is quite different:

```
mysql> INSERT INTO rcl VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
 -> FROM INFORMATION_SCHEMA.PARTITIONS
 -> WHERE TABLE_NAME = 'rcl';
+-----+-----+-----+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p | p0 | 2 |
| p | p1 | 1 |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

This is because we are comparing rows rather than scalar values. We can compare the row values inserted with the limiting row value from the `VALUES THAN LESS THAN` clause used to define partition `p0` in table `rcl`, like this:

```
mysql> SELECT (5,10) < (5,12), (5,11) < (5,12), (5,12) < (5,12);
+-----+-----+-----+
| (5,10) < (5,12) | (5,11) < (5,12) | (5,12) < (5,12) |
+-----+-----+-----+
| 1 | 1 | 0 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

The 2 tuples `(5,10)` and `(5,11)` evaluate as less than `(5,12)`, so they are stored in partition `p0`. Since 5 is not less than 5 and 12 is not less than 12, `(5,12)` is considered not less than `(5,12)`, and is stored in partition `p1`.

The `SELECT` statement in the preceding example could also have been written using explicit row constructors, like this:

```
SELECT ROW(5,10) < ROW(5,12), ROW(5,11) < ROW(5,12), ROW(5,12) < ROW(5,12);
```

For more information about the use of row constructors in MySQL, see [Section 13.2.10.5, “Row Subqueries”](#).

For a table partitioned by `RANGE COLUMNS` using only a single partitioning column, the storing of rows in partitions is the same as that of an equivalent table that is partitioned by `RANGE`. The following `CREATE TABLE` statement creates a table partitioned by `RANGE COLUMNS` using 1 partitioning column:

```
CREATE TABLE rx (
 a INT,
 b INT
)
PARTITION BY RANGE COLUMNS (a) (
 PARTITION p0 VALUES LESS THAN (5),
 PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert the rows `(5,10)`, `(5,11)`, and `(5,12)` into this table, we can see that their placement is the same as it is for the table `r` we created and populated earlier:

```
mysql> INSERT INTO rx VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
 -> FROM INFORMATION_SCHEMA.PARTITIONS
 -> WHERE TABLE_NAME = 'rx';
+-----+-----+-----+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p | p0 | 0 |
| p | p1 | 3 |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

It is also possible to create tables partitioned by `RANGE COLUMNS` where limiting values for one or more columns are repeated in successive partition definitions. You can do this as long as the tuples of column values used to define the partitions are strictly increasing. For example, each of the following `CREATE TABLE` statements is valid:

```
CREATE TABLE rc2 (
 a INT,
 b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
 PARTITION p0 VALUES LESS THAN (0,10),
 PARTITION p1 VALUES LESS THAN (10,20),
 PARTITION p2 VALUES LESS THAN (10,30),
 PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);

CREATE TABLE rc3 (
 a INT,
 b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
 PARTITION p0 VALUES LESS THAN (0,10),
 PARTITION p1 VALUES LESS THAN (10,20),
 PARTITION p2 VALUES LESS THAN (10,30),
 PARTITION p3 VALUES LESS THAN (10,35),
 PARTITION p4 VALUES LESS THAN (20,40),
 PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

The following statement also succeeds, even though it might appear at first glance that it would not, since the limiting value of column `b` is 25 for partition `p0` and 20 for partition `p1`, and the limiting value of column `c` is 100 for partition `p1` and 50 for partition `p2`:

```
CREATE TABLE rc4 (
 a INT,
 b INT,
```

```

 c INT
)
PARTITION BY RANGE COLUMNS(a,b,c) (
 PARTITION p0 VALUES LESS THAN (0,25,50),
 PARTITION p1 VALUES LESS THAN (10,20,100),
 PARTITION p2 VALUES LESS THAN (10,30,50)
 PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
);

```

When designing tables partitioned by `RANGE COLUMNS`, you can always test successive partition definitions by comparing the desired tuples using the `mysql` client, like this:

```
mysql> SELECT (0,25,50) < (10,20,100), (10,20,100) < (10,30,50);
+-----+-----+
| (0,25,50) < (10,20,100) | (10,20,100) < (10,30,50) |
+-----+-----+
| 1 | 1 |
+-----+-----+
1 row in set (0.00 sec)
```

If a `CREATE TABLE` statement contains partition definitions that are not in strictly increasing order, it fails with an error, as shown in this example:

```
mysql> CREATE TABLE rcf (
 -> a INT,
 -> b INT,
 -> c INT
 ->)
 -> PARTITION BY RANGE COLUMNS(a,b,c) (
 -> PARTITION p0 VALUES LESS THAN (0,25,50),
 -> PARTITION p1 VALUES LESS THAN (20,20,100),
 -> PARTITION p2 VALUES LESS THAN (10,30,50),
 -> PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
 ->);
ERROR 1493 (HY000): VALUES LESS THAN value must be strictly increasing for each partition
```

When you get such an error, you can deduce which partition definitions are invalid by making “less than” comparisons between their column lists. In this case, the problem is with the definition of partition `p2` because the tuple used to define it is not less than the tuple used to define partition `p3`, as shown here:

```
mysql> SELECT (0,25,50) < (20,20,100), (20,20,100) < (10,30,50);
+-----+-----+
| (0,25,50) < (20,20,100) | (20,20,100) < (10,30,50) |
+-----+-----+
| 1 | 0 |
+-----+-----+
1 row in set (0.00 sec)
```

It is also possible for `MAXVALUE` to appear for the same column in more than one `VALUES LESS THAN` clause when using `RANGE COLUMNS`. However, the limiting values for individual columns in successive partition definitions should otherwise be increasing, there should be no more than one partition defined where `MAXVALUE` is used as the upper limit for all column values, and this partition definition should appear last in the list of `PARTITION ... VALUES LESS THAN` clauses. In addition, you cannot use `MAXVALUE` as the limiting value for the first column in more than one partition definition.

As stated previously, it is also possible with `RANGE COLUMNS` partitioning to use non-integer columns as partitioning columns. (See [Section 22.2.3, “COLUMNS Partitioning](#), for a complete listing of these.) Consider a table named `employees` (which is not partitioned), created using the following statement:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT NOT NULL,
 store_id INT NOT NULL
);
```

Using `RANGE COLUMNS` partitioning, you can create a version of this table that stores each row in one of four partitions based on the employee's last name, like this:

```
CREATE TABLE employees_by_lname (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT NOT NULL,
 store_id INT NOT NULL
)
PARTITION BY RANGE COLUMNS (lname) (
 PARTITION p0 VALUES LESS THAN ('g'),
 PARTITION p1 VALUES LESS THAN ('m'),
 PARTITION p2 VALUES LESS THAN ('t'),
 PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

Alternatively, you could cause the `employees` table as created previously to be partitioned using this scheme by executing the following `ALTER TABLE` statement:

```
ALTER TABLE employees PARTITION BY RANGE COLUMNS (lname) (
 PARTITION p0 VALUES LESS THAN ('g'),
 PARTITION p1 VALUES LESS THAN ('m'),
 PARTITION p2 VALUES LESS THAN ('t'),
 PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

#### Note

Because different character sets and collations have different sort orders, the character sets and collations in use may effect which partition of a table partitioned by `RANGE COLUMNS` a given row is stored in when using string columns as partitioning columns. In addition, changing the character set or collation for a given database, table, or column after such a table is created may cause changes in how rows are distributed. For example, when using a case-sensitive collation, '`and`' sorts before '`Andersen`', but when using a collation that is case-insensitive, the reverse is true.

For information about how MySQL handles character sets and collations, see [Chapter 10, "Character Sets, Collations, Unicode"](#).

Similarly, you can cause the `employees` table to be partitioned in such a way that each row is stored in one of several partitions based on the decade in which the corresponding employee was hired using the `ALTER TABLE` statement shown here:

```
ALTER TABLE employees PARTITION BY RANGE COLUMNS (hired) (
 PARTITION p0 VALUES LESS THAN ('1970-01-01'),
 PARTITION p1 VALUES LESS THAN ('1980-01-01'),
 PARTITION p2 VALUES LESS THAN ('1990-01-01'),
 PARTITION p3 VALUES LESS THAN ('2000-01-01'),
 PARTITION p4 VALUES LESS THAN ('2010-01-01'),
 PARTITION p5 VALUES LESS THAN (MAXVALUE)
);
```

See [Section 13.1.18, "CREATE TABLE Statement"](#), for additional information about `PARTITION BY RANGE COLUMNS` syntax.

### 22.2.3.2 LIST COLUMNS partitioning

MySQL 5.7 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables the use of multiple columns as partition keys, and for columns of data types other than integer types to be used as partitioning columns; you can use string types, `DATE`, and `DATETIME` columns. (For more information about permitted data types for `COLUMNS` partitioning columns, see [Section 22.2.3, "COLUMNS Partitioning"](#).)

Suppose that you have a business that has customers in 12 cities which, for sales and marketing purposes, you organize into 4 regions of 3 cities each as shown in the following table:

| Region | Cities                         |
|--------|--------------------------------|
| 1      | Oskarshamn, Högsby, Mönsterås  |
| 2      | Vimmerby, Hultsfred, Västervik |
| 3      | Nässjö, Eksjö, Vetlanda        |
| 4      | Uppvidinge, Alvesta, Växjo     |

With `LIST COLUMNS` partitioning, you can create a table for customer data that assigns a row to any of 4 partitions corresponding to these regions based on the name of the city where a customer resides, as shown here:

```
CREATE TABLE customers_1 (
 first_name VARCHAR(25),
 last_name VARCHAR(25),
 street_1 VARCHAR(30),
 street_2 VARCHAR(30),
 city VARCHAR(15),
 renewal DATE
)
PARTITION BY LIST COLUMNS(city) (
 PARTITION pRegion_1 VALUES IN('Oskarshamn', 'Högsby', 'Mönsterås'),
 PARTITION pRegion_2 VALUES IN('Vimmerby', 'Hultsfred', 'Västervik'),
 PARTITION pRegion_3 VALUES IN('Nässjö', 'Eksjö', 'Vetlanda'),
 PARTITION pRegion_4 VALUES IN('Uppvidinge', 'Alvesta', 'Växjo')
);
```

As with partitioning by `RANGE COLUMNS`, you do not need to use expressions in the `COLUMNS()` clause to convert column values into integers. (In fact, the use of expressions other than column names is not permitted with `COLUMNS()`.)

It is also possible to use `DATE` and `DATETIME` columns, as shown in the following example that uses the same name and columns as the `customers_1` table shown previously, but employs `LIST COLUMNS` partitioning based on the `renewal` column to store rows in one of 4 partitions depending on the week in February 2010 the customer's account is scheduled to renew:

```
CREATE TABLE customers_2 (
 first_name VARCHAR(25),
 last_name VARCHAR(25),
 street_1 VARCHAR(30),
 street_2 VARCHAR(30),
 city VARCHAR(15),
 renewal DATE
)
PARTITION BY LIST COLUMNS(renewal) (
 PARTITION pWeek_1 VALUES IN('2010-02-01', '2010-02-02', '2010-02-03',
 '2010-02-04', '2010-02-05', '2010-02-06', '2010-02-07'),
 PARTITION pWeek_2 VALUES IN('2010-02-08', '2010-02-09', '2010-02-10',
 '2010-02-11', '2010-02-12', '2010-02-13', '2010-02-14'),
 PARTITION pWeek_3 VALUES IN('2010-02-15', '2010-02-16', '2010-02-17',
 '2010-02-18', '2010-02-19', '2010-02-20', '2010-02-21'),
 PARTITION pWeek_4 VALUES IN('2010-02-22', '2010-02-23', '2010-02-24',
 '2010-02-25', '2010-02-26', '2010-02-27', '2010-02-28')
);
```

This works, but becomes cumbersome to define and maintain if the number of dates involved grows very large; in such cases, it is usually more practical to employ `RANGE` or `RANGE COLUMNS` partitioning instead. In this case, since the column we wish to use as the partitioning key is a `DATE` column, we use `RANGE COLUMNS` partitioning, as shown here:

```
CREATE TABLE customers_3 (
 first_name VARCHAR(25),
 last_name VARCHAR(25),
 street_1 VARCHAR(30),
```

```

 street_2 VARCHAR(30),
 city VARCHAR(15),
 renewal DATE
)
PARTITION BY RANGE COLUMNS(renewal) (
 PARTITION pWeek_1 VALUES LESS THAN('2010-02-09'),
 PARTITION pWeek_2 VALUES LESS THAN('2010-02-15'),
 PARTITION pWeek_3 VALUES LESS THAN('2010-02-22'),
 PARTITION pWeek_4 VALUES LESS THAN('2010-03-01')
);

```

See [Section 22.2.3.1, “RANGE COLUMNS partitioning”](#), for more information.

In addition (as with `RANGE COLUMNS` partitioning), you can use multiple columns in the `COLUMNS()` clause.

See [Section 13.1.18, “CREATE TABLE Statement”](#), for additional information about `PARTITION BY LIST COLUMNS()` syntax.

## 22.2.4 HASH Partitioning

Partitioning by `HASH` is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using `HASH` partitioning, it is necessary to append to the `CREATE TABLE` statement a `PARTITION BY HASH(expr)` clause, where `expr` is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you most likely want to follow this with `PARTITIONS num`, where `num` is a positive integer representing the number of partitions into which the table is to be divided.

### Note

For simplicity, the tables in the examples that follow do not use any keys. You should be aware that, if a table has any unique keys, every column used in the partitioning expression for this table must be part of every unique key, including the primary key. See [Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#), for more information.

The following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```

CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;

```

If you do not include a `PARTITIONS` clause, the number of partitions defaults to 1.

Using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for `expr`. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```

CREATE TABLE employees (
 id INT NOT NULL,

```

```

 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY HASH(YEAR(hired))
PARTITIONS 4;

```

*expr* must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in [Section 22.6, “Restrictions and Limitations on Partitioning”](#). You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where `date_col` is a column of type `DATE`, then the expression `TO_DAYS(date_col)` is said to vary directly with the value of `date_col`, because for every change in the value of `date_col`, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` with respect to `date_col` is not quite as direct as that of `TO_DAYS(date_col)`, because not every possible change in `date_col` produces an equivalent change in `YEAR(date_col)`. Even so, `YEAR(date_col)` is a good candidate for a hashing function, because it varies directly with a portion of `date_col` and there is no possible change in `date_col` that produces a disproportionate change in `YEAR(date_col)`.

By way of contrast, suppose that you have a column named `int_col` whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6`. This would be a poor choice for a hashing function because a change in the value of `int_col` is not guaranteed to produce a proportional change in the value of the expression. Changing the value of `int_col` by a given amount can produce widely differing changes in the value of the expression. For example, changing `int_col` from 5 to 6 produces a change of -1 in the value of the expression, but changing the value of `int_col` from 6 to 7 produces a change of -7 in the expression value.

In other words, the more closely the graph of the column value versus the value of the expression follows a straight line as traced by the equation `y=cx` where `c` is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of `num` partitions to use based on the modulus of the result of the expression. In other words, for a given expression *expr*, the partition in which the record is stored is partition number `N`, where `N = MOD(expr, num)`. Suppose that table `t1` is defined as follows, so that it has 4 partitions:

```

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
 PARTITION BY HASH(YEAR(col3))
 PARTITIONS 4;

```

If you insert a record into `t1` whose `col3` value is '2005-09-15', then the partition in which it is stored is determined as follows:

```

MOD(YEAR('2005-09-01'),4)
= MOD(2005,4)
= 1

```

MySQL 5.7 also supports a variant of `HASH` partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See [Section 22.2.4.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm.

The user-supplied expression is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

#### 22.2.4.1 LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the `LINEAR` keyword in the `PARTITION BY` clause, as shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY LINEAR HASH(YEAR(hired))
PARTITIONS 4;
```

Given an expression `expr`, the partition in which the record is stored when linear hashing is used is partition number `N` from among `num` partitions, where `N` is derived according to the following algorithm:

1. Find the next power of 2 greater than `num`. We call this value `V`; it can be calculated as:

```
V = POWER(2, CEILING(LOG(2, num)))
```

(Suppose that `num` is 13. Then `LOG(2, 13)` is 3.7004397181411. `CEILING(3.7004397181411)` is 4, and `V = POWER(2, 4)`, which is 16.)

2. Set `N = F(column_list) & (V - 1)`.
3. While `N >= num`:
  - Set `V = V / 2`
  - Set `N = N & (V - 1)`

Suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR HASH(YEAR(col3))
PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values '`2003-04-14`' and '`1998-10-19`'. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING(LOG(2, 6))) = 8
N = YEAR('2003-04-14') & (8 - 1)
 = 2003 & 7
 = 3

(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
```

```

N = YEAR('1998-10-19') & (8 - 1)
= 1998 & 7
= 6

(6 >= 6 is TRUE: additional step required)

N = 6 & ((8 / 2) - 1)
= 6 & 3
= 2

(2 >= 6 is FALSE: record stored in partition #2)

```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

## 22.2.5 KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. NDB Cluster uses `MD5()` for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as `PASSWORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- `KEY` is used rather than `HASH`.
- `KEY` takes only a list of zero or more column names. Any columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 5.7:

```

CREATE TABLE k1 (
 id INT NOT NULL PRIMARY KEY,
 name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;

```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```

CREATE TABLE k1 (
 id INT NOT NULL,
 name VARCHAR(20),
 UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;

```

However, if the unique key column were not defined as `NOT NULL`, then the previous statement would fail.

In both of these cases, the partitioning key is the `id` column, even though it is not shown in the output of `SHOW CREATE TABLE` or in the `PARTITION_EXPRESSION` column of the `INFORMATION_SCHEMA.PARTITIONS` table.

Unlike the case with other partitioning types, columns used for partitioning by `KEY` are not restricted to integer or `NULL` values. For example, the following `CREATE TABLE` statement is valid:

```

CREATE TABLE tm1 (
 s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)

```

```
PARTITIONS 10;
```

The preceding statement would *not* be valid, were a different partitioning type to be specified. (In this case, simply using `PARTITION BY KEY()` would also be valid and have the same effect as `PARTITION BY KEY(s1)`, since `s1` is the table's primary key.)

For additional information about this issue, see [Section 22.6, “Restrictions and Limitations on Partitioning”](#).

Columns with index prefixes are not supported in partitioning keys. This means that `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns can be used in a partitioning key, as long as they do not employ prefixes; because a prefix must be specified for `BLOB` and `TEXT` columns in index definitions, it is not possible to use columns of these two types in partitioning keys. In MySQL 5.7, columns using prefixes are permitted when creating, altering, or upgrading partitioned tables, even though they are not included in the table's partitioning key. This is a known issue in MySQL 5.7 which is addressed in MySQL 8.0, where this permissive behavior is deprecated, and the server displays appropriate warnings or errors when attempting to use such columns in these cases. See [Column index prefixes not supported for key partitioning](#), for more information and examples.

#### Note

Tables using the `NDB` storage engine are implicitly partitioned by `KEY`, using the table's primary key as the partitioning key (as with other MySQL storage engines). In the event that the `NDB` Cluster table has no explicit primary key, the “hidden” primary key generated by the `NDB` storage engine for each `NDB` Cluster table is used as the partitioning key.

If you define an explicit partitioning scheme for an `NDB` table, the table must have an explicit primary key, and any columns used in the partitioning expression must be part of this key. However, if the table uses an “empty” partitioning expression—that is, `PARTITION BY KEY()` with no column references—then no explicit primary key is required.

You can observe this partitioning using the `ndb_desc` utility (with the `-p` option).

#### Important

For a key-partitioned table, you cannot execute an `ALTER TABLE DROP PRIMARY KEY`, as doing so generates the error `ERROR 1466 (HY000): Field in list of fields for partition function not found in table`. This is not an issue for `NDB` Cluster tables which are partitioned by `KEY`; in such cases, the table is reorganized using the “hidden” primary key as the table's new partitioning key. See [Chapter 21, MySQL NDB Cluster 7.5 and NDB Cluster 7.6](#).

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
 col1 INT NOT NULL,
 col2 CHAR(5),
 col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

Using `LINEAR` has the same effect on `KEY` partitioning as it does on `HASH` partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See [Section 22.2.4.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm and its implications.

## 22.2.6 Subpartitioning

Subpartitioning—also known as *composite partitioning*—is the further division of each partition in a partitioned table. Consider the following `CREATE TABLE` statement:

```
CREATE TABLE ts (id INT, purchased DATE)
 PARTITION BY RANGE(YEAR(purchased))
 SUBPARTITION BY HASH(TO_DAYS(purchased))
 SUBPARTITIONS 2 (
 PARTITION p0 VALUES LESS THAN (1990),
 PARTITION p1 VALUES LESS THAN (2000),
 PARTITION p2 VALUES LESS THAN MAXVALUE
);

```

Table `ts` has 3 `RANGE` partitions. Each of these partitions—`p0`, `p1`, and `p2`—is further divided into 2 subpartitions. In effect, the entire table is divided into  $3 * 2 = 6$  partitions. However, due to the action of the `PARTITION BY RANGE` clause, the first 2 of these store only those records with a value less than 1990 in the `purchased` column.

In MySQL 5.7, it is possible to subpartition tables that are partitioned by `RANGE` or `LIST`. Subpartitions may use either `HASH` or `KEY` partitioning. This is also known as *composite partitioning*.

### Note

`SUBPARTITION BY HASH` and `SUBPARTITION BY KEY` generally follow the same syntax rules as `PARTITION BY HASH` and `PARTITION BY KEY`, respectively. An exception to this is that `SUBPARTITION BY KEY` (unlike `PARTITION BY KEY`) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see [Issues with subpartitions](#), for more information and an example.

It is also possible to define subpartitions explicitly using `SUBPARTITION` clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
 PARTITION BY RANGE(YEAR(purchased))
 SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0,
 SUBPARTITION s1
),
 PARTITION p1 VALUES LESS THAN (2000) (
 SUBPARTITION s2,
 SUBPARTITION s3
),
 PARTITION p2 VALUES LESS THAN MAXVALUE (
 SUBPARTITION s4,
 SUBPARTITION s5
)
);

```

Some syntactical items of note are listed here:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement fails:

```
CREATE TABLE ts (id INT, purchased DATE)
 PARTITION BY RANGE(YEAR(purchased))
 SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0,
 SUBPARTITION s1
),
 PARTITION p1 VALUES LESS THAN (2000),
 PARTITION p2 VALUES LESS THAN MAXVALUE (

```

```

 SUBPARTITION s2,
 SUBPARTITION s3
)
);

```

This statement would still fail even if it included a `SUBPARTITIONS 2` clause.

- Each `SUBPARTITION` clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.
- Subpartition names must be unique across the entire table. For example, the following `CREATE TABLE` statement is valid in MySQL 5.7:

```

CREATE TABLE ts (id INT, purchased DATE)
 PARTITION BY RANGE(YEAR(purchased))
 SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0,
 SUBPARTITION s1
),
 PARTITION p1 VALUES LESS THAN (2000) (
 SUBPARTITION s2,
 SUBPARTITION s3
),
 PARTITION p2 VALUES LESS THAN MAXVALUE (
 SUBPARTITION s4,
 SUBPARTITION s5
)
);

```

Subpartitions can be used with especially large `MyISAM` tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```

CREATE TABLE ts (id INT, purchased DATE)
 ENGINE = MYISAM
 PARTITION BY RANGE(YEAR(purchased))
 SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0
 DATA DIRECTORY = '/disk0/data'
 INDEX DIRECTORY = '/disk0/idx',
 SUBPARTITION s1
 DATA DIRECTORY = '/disk1/data'
 INDEX DIRECTORY = '/disk1/idx'
),
 PARTITION p1 VALUES LESS THAN (2000) (
 SUBPARTITION s2
 DATA DIRECTORY = '/disk2/data'
 INDEX DIRECTORY = '/disk2/idx',
 SUBPARTITION s3
 DATA DIRECTORY = '/disk3/data'
 INDEX DIRECTORY = '/disk3/idx'
),
 PARTITION p2 VALUES LESS THAN MAXVALUE (
 SUBPARTITION s4
 DATA DIRECTORY = '/disk4/data'
 INDEX DIRECTORY = '/disk4/idx',
 SUBPARTITION s5
 DATA DIRECTORY = '/disk5/data'
 INDEX DIRECTORY = '/disk5/idx'
)
);

```

In this case, a separate disk is used for the data and for the indexes of each `RANGE`. Many other variations are possible; another example might be:

```

CREATE TABLE ts (id INT, purchased DATE)
 ENGINE = MYISAM

```

```

PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0a
 DATA DIRECTORY = '/disk0'
 INDEX DIRECTORY = '/disk1',
 SUBPARTITION s0b
 DATA DIRECTORY = '/disk2'
 INDEX DIRECTORY = '/disk3'
),
 PARTITION p1 VALUES LESS THAN (2000) (
 SUBPARTITION s1a
 DATA DIRECTORY = '/disk4/data'
 INDEX DIRECTORY = '/disk4/idx',
 SUBPARTITION s1b
 DATA DIRECTORY = '/disk5/data'
 INDEX DIRECTORY = '/disk5/idx'
),
 PARTITION p2 VALUES LESS THAN MAXVALUE (
 SUBPARTITION s2a,
 SUBPARTITION s2b
)
);

```

Here, the storage is as follows:

- Rows with `purchased` dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (`s0a` and `s0b`) making up partition `p0`. In other words:
  - The data for subpartition `s0a` is stored on `/disk0`.
  - The indexes for subpartition `s0a` are stored on `/disk1`.
  - The data for subpartition `s0b` is stored on `/disk2`.
  - The indexes for subpartition `s0b` are stored on `/disk3`.
- Rows containing dates ranging from 1990 to 1999 (partition `p1`) do not require as much room as those from before 1990. These are split between 2 disks (`/disk4` and `/disk5`) rather than 4 disks as with the legacy records stored in `p0`:
  - Data and indexes belonging to `p1`'s first subpartition (`s1a`) are stored on `/disk4`—the data in `/disk4/data`, and the indexes in `/disk4/idx`.
  - Data and indexes belonging to `p1`'s second subpartition (`s1b`) are stored on `/disk5`—the data in `/disk5/data`, and the indexes in `/disk5/idx`.
- Rows reflecting dates from the year 2000 to the present (partition `p2`) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an `ALTER TABLE ... REORGANIZE PARTITION` statement. See [Section 22.3, “Partition Management”](#), for an explanation of how this can be done.

The `DATA DIRECTORY` and `INDEX DIRECTORY` options are not permitted in partition definitions when the `NO_DIR_IN_CREATE` server SQL mode is in effect. In MySQL 5.7, these options are also not permitted when defining subpartitions (Bug #42954).

## 22.2.7 How MySQL Partitioning Handles NULL

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use

`NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. MySQL's partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles `NULL` values when determining the partition in which a row should be stored, and provide examples for each.

**Handling of NULL with RANGE partitioning.** If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition. Consider these two tables in a database named `p`, created as follows:

```
mysql> CREATE TABLE t1 (
 -> c1 INT,
 -> c2 VARCHAR(20)
 ->)
 -> PARTITION BY RANGE(c1) (
 -> PARTITION p0 VALUES LESS THAN (0),
 -> PARTITION p1 VALUES LESS THAN (10),
 -> PARTITION p2 VALUES LESS THAN MAXVALUE
 ->);
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE t2 (
 -> c1 INT,
 -> c2 VARCHAR(20)
 ->)
 -> PARTITION BY RANGE(c1) (
 -> PARTITION p0 VALUES LESS THAN (-5),
 -> PARTITION p1 VALUES LESS THAN (0),
 -> PARTITION p2 VALUES LESS THAN (10),
 -> PARTITION p3 VALUES LESS THAN MAXVALUE
 ->);
Query OK, 0 rows affected (0.09 sec)
```

You can see the partitions created by these two `CREATE TABLE` statements using the following query against the `PARTITIONS` table in the `INFORMATION_SCHEMA` database:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
 > FROM INFORMATION_SCHEMA.PARTITIONS
 > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| t1 | p0 | 0 | 0 | 0 |
| t1 | p1 | 0 | 0 | 0 |
| t1 | p2 | 0 | 0 | 0 |
| t2 | p0 | 0 | 0 | 0 |
| t2 | p1 | 0 | 0 | 0 |
| t2 | p2 | 0 | 0 | 0 |
| t2 | p3 | 0 | 0 | 0 |
+-----+-----+-----+-----+-----+
7 rows in set (0.00 sec)
```

(For more information about this table, see [Section 24.3.16, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#).) Now let us populate each of these tables with a single row containing a `NULL` in the column used as the partitioning key, and verify that the rows were inserted using a pair of `SELECT` statements:

```
mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+-----+-----+
| id | name |
+-----+-----+
```

```
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+-----+-----+
| id | name |
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)
```

You can see which partitions are used to store the inserted rows by rerunning the previous query against `INFORMATION_SCHEMA.PARTITIONS` and inspecting the output:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
 > FROM INFORMATION_SCHEMA.PARTITIONS
 > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| t1 | p0 | 1 | 20 | 20 |
| t1 | p1 | 0 | 0 | 0 |
| t1 | p2 | 0 | 0 | 0 |
| t2 | p0 | 1 | 20 | 20 |
| t2 | p1 | 0 | 0 | 0 |
| t2 | p2 | 0 | 0 | 0 |
| t2 | p3 | 0 | 0 | 0 |
+-----+-----+-----+-----+-----+
7 rows in set (0.01 sec)
```

You can also demonstrate that these rows were stored in the lowest partition of each table by dropping these partitions, and then re-running the `SELECT` statements:

```
mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

(For more information on `ALTER TABLE ... DROP PARTITION`, see [Section 13.1.8, “ALTER TABLE Statement”](#).)

`NULL` is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a `CREATE TABLE` statement such as this one:

```
CREATE TABLE tndate (
 id INT,
 dt DATE
)
PARTITION BY RANGE(YEAR(dt)) (
 PARTITION p0 VALUES LESS THAN (1990),
 PARTITION p1 VALUES LESS THAN (2000),
 PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, `YEAR(NULL)` returns `NULL`. A row with a `dt` column value of `NULL` is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

**Handling of NULL with LIST partitioning.** A table that is partitioned by `LIST` admits `NULL` values if and only if one of its partitions is defined using that value-list that contains `NULL`. The converse of

this is that a table partitioned by `LIST` which does not explicitly use `NULL` in a value list rejects rows resulting in a `NULL` value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (
-> c1 INT,
-> c2 VARCHAR(20)
->)
-> PARTITION BY LIST(c1) (
-> PARTITION p0 VALUES IN (0, 3, 6),
-> PARTITION p1 VALUES IN (1, 4, 7),
-> PARTITION p2 VALUES IN (2, 5, 8)
->);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL
```

Only rows having a `c1` value between 0 and 8 inclusive can be inserted into `ts1`. `NULL` falls outside this range, just like the number 9. We can create tables `ts2` and `ts3` having value lists containing `NULL`, as shown here:

```
mysql> CREATE TABLE ts2 (
-> c1 INT,
-> c2 VARCHAR(20)
->)
-> PARTITION BY LIST(c1) (
-> PARTITION p0 VALUES IN (0, 3, 6),
-> PARTITION p1 VALUES IN (1, 4, 7),
-> PARTITION p2 VALUES IN (2, 5, 8),
-> PARTITION p3 VALUES IN (NULL)
->);
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
-> c1 INT,
-> c2 VARCHAR(20)
->)
-> PARTITION BY LIST(c1) (
-> PARTITION p0 VALUES IN (0, 3, 6),
-> PARTITION p1 VALUES IN (1, 4, 7, NULL),
-> PARTITION p2 VALUES IN (2, 5, 8)
->);
Query OK, 0 rows affected (0.01 sec)
```

When defining value lists for partitioning, you can (and should) treat `NULL` just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7)`, `VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```
mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `p` database):

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';
+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+
| ts2 | p0 | 0 | 0 | 0 |
| ts2 | p1 | 0 | 0 | 0 |
```

## How MySQL Partitioning Handles NULL

```
| ts2 | p2 | 0 | 0 | 0 |
| ts2 | p3 | 1 | 20 | 20 |
| ts3 | p0 | 0 | 0 | 0 |
| ts3 | p1 | 1 | 20 | 20 |
| ts3 | p2 | 0 | 0 | 0 |
+-----+-----+-----+-----+-----+
7 rows in set (0.01 sec)
```

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a `SELECT`.

**Handling of NULL with HASH and KEY partitioning.** `NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th` (also in the `p` database) created using the following statement:

```
mysql> CREATE TABLE th (
 -> c1 INT,
 -> c2 VARCHAR(20)
 ->)
 -> PARTITION BY HASH(c1)
 -> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)
```

The partitions belonging to this table can be viewed using the query shown here:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
 > FROM INFORMATION_SCHEMA.PARTITIONS
 > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| th | p0 | 0 | 0 | 0 |
| th | p1 | 0 | 0 | 0 |
+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

`TABLE_ROWS` for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted, as shown here:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;
+-----+-----+
| c1 | c2 |
+-----+-----+
| NULL | mothra |
+-----+-----+
| 0 | gigan |
+-----+-----+
2 rows in set (0.01 sec)
```

Recall that for any integer `N`, the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as 0. Checking the `INFORMATION_SCHEMA.PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
 > FROM INFORMATION_SCHEMA.PARTITIONS
 > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| th | p0 | 2 | 20 | 20 |
| th | p1 | 0 | 0 | 0 |
+-----+-----+-----+-----+-----+
```

```
2 rows in set (0.00 sec)
```

By repeating the last example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify that `NULL` is also treated like 0 for this type of partitioning.

## 22.3 Partition Management

MySQL 5.7 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` statement. There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see [Section 22.3.1, “Management of RANGE and LIST Partitions”](#).
- For a discussion of managing `HASH` and `KEY` partitions, see [Section 22.3.2, “Management of HASH and KEY Partitions”](#).
- See [Section 22.3.5, “Obtaining Information About Partitions”](#), for a discussion of mechanisms provided in MySQL 5.7 for obtaining information about partitioned tables and partitions.
- For a discussion of performing maintenance operations on partitions, see [Section 22.3.4, “Maintenance of Partitions”](#).

### Note

In MySQL 5.7, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` statement with a `partition_options` clause. This clause has the same syntax as that used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. Suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
 PARTITION BY RANGE(YEAR(purchased))
 PARTITION p0 VALUES LESS THAN (1990),
 PARTITION p1 VALUES LESS THAN (1995),
 PARTITION p2 VALUES LESS THAN (2000),
 PARTITION p3 VALUES LESS THAN (2005)
 ;
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`.

`ALTER TABLE ... ENGINE = ...` changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. Use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning. See [Section 13.1.8, “ALTER TABLE Statement”](#).

### Important

Only a single `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARTITION`).

In MySQL 5.7, it is possible to delete all rows from one or more selected partitions using `ALTER TABLE ... TRUNCATE PARTITION`.

### 22.3.1 Management of RANGE and LIST Partitions

Adding and dropping of range and list partitions are handled in a similar fashion, so we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see [Section 22.3.2, “Management of HASH and KEY Partitions”](#).

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with the `DROP PARTITION` option. Suppose that you have created a table that is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
 -> PARTITION BY RANGE(YEAR(purchased)) (
 -> PARTITION p0 VALUES LESS THAN (1990),
 -> PARTITION p1 VALUES LESS THAN (1995),
 -> PARTITION p2 VALUES LESS THAN (2000),
 -> PARTITION p3 VALUES LESS THAN (2005),
 -> PARTITION p4 VALUES LESS THAN (2010),
 -> PARTITION p5 VALUES LESS THAN (2015)
 ->);
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO tr VALUES
 -> (1, 'desk organiser', '2003-10-15'),
 -> (2, 'alarm clock', '1997-11-05'),
 -> (3, 'chair', '2009-03-10'),
 -> (4, 'bookcase', '1989-01-10'),
 -> (5, 'exercise bike', '2014-05-09'),
 -> (6, 'sofa', '1987-06-05'),
 -> (7, 'espresso maker', '2011-11-22'),
 -> (8, 'aquarium', '1992-08-04'),
 -> (9, 'study desk', '2006-09-16'),
 -> (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.05 sec)
Records: 10 Duplicates: 0 Warnings: 0
```

You can see which items should have been inserted into partition `p2` as shown here:

```
mysql> SELECT * FROM tr
 -> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+----+-----+-----+
| id | name | purchased |
+----+-----+-----+
| 2 | alarm clock | 1997-11-05 |
| 10 | lava lamp | 1998-12-25 |
+----+-----+-----+
2 rows in set (0.00 sec)
```

You can also get this information using partition selection, as shown here:

```
mysql> SELECT * FROM tr PARTITION (p2);
+----+-----+-----+
| id | name | purchased |
+----+-----+-----+
| 2 | alarm clock | 1997-11-05 |
| 10 | lava lamp | 1998-12-25 |
+----+-----+-----+
2 rows in set (0.00 sec)
```

See [Section 22.5, “Partition Selection”](#), for more information.

To drop the partition named `p2`, execute the following command:

```
mysql> ALTER TABLE tr DROP PARTITION p2;
```

```
Query OK, 0 rows affected (0.03 sec)
```

### Note

The `NDBCLUSTER` storage engine does not support `ALTER TABLE ... DROP PARTITION`. It does, however, support the other partitioning-related extensions to `ALTER TABLE` that are described in this chapter.

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous `SELECT` query:

```
mysql> SELECT * FROM tr WHERE purchased
 -> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)
```

Because of this, you must have the `DROP` privilege for a table before you can execute `ALTER TABLE ... DROP PARTITION` on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` statement. (See [Section 13.1.34, “TRUNCATE TABLE Statement”](#).)

If you intend to change the partitioning of a table *without* losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in [Section 13.1.8, “ALTER TABLE Statement”](#), for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` statement, you can see how the partitioning makeup of the table has been changed:

```
mysql> SHOW CREATE TABLE tr\G
*****1. row *****
 Table: tr
Create Table: CREATE TABLE `tr` (
 `id` int(11) DEFAULT NULL,
 `name` varchar(50) DEFAULT NULL,
 `purchased` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE (YEAR(purchased))
(PARTITION p0 VALUES LESS THAN (1990) ENGINE = InnoDB,
 PARTITION p1 VALUES LESS THAN (1995) ENGINE = InnoDB,
 PARTITION p3 VALUES LESS THAN (2005) ENGINE = InnoDB,
 PARTITION p4 VALUES LESS THAN (2010) ENGINE = InnoDB,
 PARTITION p5 VALUES LESS THAN (2015) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

When you insert new rows into the changed table with `purchased` column values between `'1995-01-01'` and `'2004-12-31'` inclusive, those rows are stored in partition `p3`. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
 -> BETWEEN '1995-01-01' AND '2004-12-31';
+----+-----+-----+
| id | name | purchased |
+----+-----+-----+
| 1 | desk organiser | 2003-10-15 |
| 11 | pencil holder | 1995-07-12 |
+----+-----+-----+
2 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
 -> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

The number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping `LIST` partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as used for dropping `RANGE` partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See [Section 22.2.2, “LIST Partitioning](#), for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by `RANGE`, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organization, which is defined as follows:

```
CREATE TABLE members (
 id INT,
 fname VARCHAR(25),
 lname VARCHAR(25),
 dob DATE
)
PARTITION BY RANGE(YEAR(dob)) (
 PARTITION p0 VALUES LESS THAN (1980),
 PARTITION p1 VALUES LESS THAN (1990),
 PARTITION p2 VALUES LESS THAN (2000)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2015, you realize that you are soon going to be admitting members who were born in 2000 (and later). You can modify the `members` table to accommodate new members born in the years 2000 to 2010 as shown here:

```
ALTER TABLE members ADD PARTITION (PARTITION p3 VALUES LESS THAN (2010));
```

With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions results in an error as shown here:

```
mysql> ALTER TABLE members
 > ADD PARTITION (
 > PARTITION n VALUES LESS THAN (1970));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly »
 increasing for each partition
```

You can work around this problem by reorganizing the first partition into two new ones that split the range between them, like this:

```
ALTER TABLE members
 REORGANIZE PARTITION p0 INTO (
 PARTITION n0 VALUES LESS THAN (1970),
 PARTITION n1 VALUES LESS THAN (1980)
);
```

Using `SHOW CREATE TABLE` you can see that the `ALTER TABLE` statement has had the desired effect:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
 Table: members
Create Table: CREATE TABLE `members` (
 `id` int(11) DEFAULT NULL,
 `fname` varchar(25) DEFAULT NULL,
 `lname` varchar(25) DEFAULT NULL,
 `dob` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE (YEAR(dob))
(PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB,
 PARTITION n1 VALUES LESS THAN (1980) ENGINE = InnoDB,
```

```
PARTITION p1 VALUES LESS THAN (1990) ENGINE = InnoDB,
PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (2010) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

See also [Section 13.1.8.1, “ALTER TABLE Partition Operations”](#).

You can also use `ALTER TABLE ... ADD PARTITION` to add new partitions to a table that is partitioned by `LIST`. Suppose a table `tt` is defined using the following `CREATE TABLE` statement:

```
CREATE TABLE tt (
 id INT,
 data INT
)
PARTITION BY LIST(data) (
 PARTITION p0 VALUES IN (5, 10, 15),
 PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the `data` column values `7`, `14`, and `21` as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Keep in mind that you *cannot* add a new `LIST` partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error results:

```
mysql> ALTER TABLE tt ADD PARTITION
 > (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
 in list partitioning
```

Because any rows with the `data` column value `12` have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes `12` in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1`—and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

You can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 hired DATE NOT NULL
)
PARTITION BY RANGE(YEAR(hired)) (
 PARTITION p1 VALUES LESS THAN (1991),
 PARTITION p2 VALUES LESS THAN (1996),
 PARTITION p3 VALUES LESS THAN (2001),
 PARTITION p4 VALUES LESS THAN (2005)
);

ALTER TABLE employees ADD PARTITION (
 PARTITION p5 VALUES LESS THAN (2010),
 PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving `RANGE` partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
```

```
Table: members
Create Table: CREATE TABLE `members` (
 `id` int(11) DEFAULT NULL,
 `fname` varchar(25) DEFAULT NULL,
 `lname` varchar(25) DEFAULT NULL,
 `dob` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE (YEAR(dob))
(PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB,
 PARTITION n1 VALUES LESS THAN (1980) ENGINE = InnoDB,
 PARTITION p1 VALUES LESS THAN (1990) ENGINE = InnoDB,
 PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,
 PARTITION p3 VALUES LESS THAN (2010) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION n0 INTO (
 PARTITION s0 VALUES LESS THAN (1960),
 PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can reverse the effect of the previous statement on the `members` table as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
 PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is shown here:

```
ALTER TABLE tbl_name
 REORGANIZE PARTITION partition_list
 INTO (partition_definitions);
```

Here, `tbl_name` is the name of the partitioned table, and `partition_list` is a comma-separated list of names of one or more existing partitions to be changed. `partition_definitions` is a comma-separated list of new partition definitions, which follow the same rules as for the `partition_definitions` list used in `CREATE TABLE`. You are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, like this:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
 PARTITION m0 VALUES LESS THAN (1980),
 PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
```

```
PARTITION p1 VALUES IN (6, 18),
PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The `PARTITION` options used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

A new `RANGE` partitioning scheme cannot have any overlapping ranges; a new `LIST` partitioning scheme cannot have any overlapping sets of values.

- The combination of partitions in the `partition_definitions` list should account for the same range or set of values overall as the combined partitions named in the `partition_list`.

For example, partitions `p1` and `p2` together cover the years 1980 through 1999 in the `members` table used as an example in this section. Any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip range partitions.

For instance, you could not reorganize the example `members` table using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, so these are not adjacent partitions. (You cannot skip partition `p1` in this case.)

- You cannot use `REORGANIZE PARTITION` to change the type of partitioning used by the table (for example, you cannot change `RANGE` partitions to `HASH` partitions or the reverse). You also cannot use this statement to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`, as shown here:

```
ALTER TABLE members
PARTITION BY HASH(YEAR(dob))
PARTITIONS 8;
```

### 22.3.2 Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see [Section 22.3.1, “Management of RANGE and LIST Partitions”](#).

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` statement. Suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```
CREATE TABLE clients (
 id INT,
 fname VARCHAR(30),
 lname VARCHAR(30),
 signed DATE
)
PARTITION BY HASH(MONTH(signed))
PARTITIONS 12;
```

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_1k (
 -> id INT,
 -> fname VARCHAR(30),
 -> lname VARCHAR(30),
 -> signed DATE
 ->)
 -> PARTITION BY LINEAR KEY(signed)
 -> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_1k COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

The number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

### 22.3.3 Exchanging Partitions and Subpartitions with Tables

In MySQL 5.7, it is possible to exchange a table partition or subpartition with a table using `ALTER TABLE pt EXCHANGE PARTITION p WITH TABLE nt`, where `pt` is the partitioned table and `p` is the partition or subpartition of `pt` to be exchanged with unpartitioned table `nt`, provided that the following statements are true:

1. Table `nt` is not itself partitioned.
2. Table `nt` is not a temporary table.
3. The structures of tables `pt` and `nt` are otherwise identical.
4. Table `nt` contains no foreign key references, and no other table has any foreign keys that refer to `nt`.
5. There are no rows in `nt` that lie outside the boundaries of the partition definition for `p`. This condition does not apply if the `WITHOUT VALIDATION` option is used. The `[ {WITH|WITHOUT} VALIDATION ]` option was added in MySQL 5.7.5.
6. For `InnoDB` tables, both tables use the same row format. To determine the row format of an `InnoDB` table, query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`.
7. `nt` does not have any partitions that use the `DATA DIRECTORY` option. This restriction is lifted for `InnoDB` tables in MySQL 5.7.25 and later.

In addition to the `ALTER`, `INSERT`, and `CREATE` privileges usually required for `ALTER TABLE` statements, you must have the `DROP` privilege to perform `ALTER TABLE ... EXCHANGE PARTITION`.

You should also be aware of the following effects of `ALTER TABLE ... EXCHANGE PARTITION`:

- Executing `ALTER TABLE ... EXCHANGE PARTITION` does not invoke any triggers on either the partitioned table or the table to be exchanged.
- Any `AUTO_INCREMENT` columns in the exchanged table are reset.
- The `IGNORE` keyword has no effect when used with `ALTER TABLE ... EXCHANGE PARTITION`.

The syntax of the `ALTER TABLE ... EXCHANGE PARTITION` statement is shown here, where `pt` is the partitioned table, `p` is the partition or subpartition to be exchanged, and `nt` is the nonpartitioned table to be exchanged with `p`:

```
ALTER TABLE pt
 EXCHANGE PARTITION p
 WITH TABLE nt;
```

Optionally, you can append a `WITH VALIDATION` or `WITHOUT VALIDATION` clause. When `WITHOUT VALIDATION` is specified, the `ALTER TABLE ... EXCHANGE PARTITION` operation does not perform row-by-row validation when exchanging a partition or nonpartitioned table, allowing database administrators to assume responsibility for ensuring that rows are within the boundaries of the partition definition. `WITH VALIDATION` is the default behavior and need not be specified explicitly. The `[{WITH|WITHOUT} VALIDATION]` option was added in MySQL 5.7.5.

One and only one partition or subpartition may be exchanged with one and only one nonpartitioned table in a single `ALTER TABLE EXCHANGE PARTITION` statement. To exchange multiple partitions or subpartitions, use multiple `ALTER TABLE EXCHANGE PARTITION` statements. `EXCHANGE PARTITION` may not be combined with other `ALTER TABLE` options. The partitioning and (if applicable) subpartitioning used by the partitioned table may be of any type or types supported in MySQL 5.7.

## Exchanging a Partition with a Nonpartitioned Table

Suppose that a partitioned table `e` has been created and populated using the following SQL statements:

```
CREATE TABLE e (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30)
)
PARTITION BY RANGE (id) (
 PARTITION p0 VALUES LESS THAN (50),
 PARTITION p1 VALUES LESS THAN (100),
 PARTITION p2 VALUES LESS THAN (150),
 PARTITION p3 VALUES LESS THAN (MAXVALUE)
);

INSERT INTO e VALUES
 (1669, "Jim", "Smith"),
 (337, "Mary", "Jones"),
 (16, "Frank", "White"),
 (2005, "Linda", "Black");
```

Now we create a nonpartitioned copy of `e` named `e2`. This can be done using the `mysql` client as shown here:

```
mysql> CREATE TABLE e2 LIKE e;
Query OK, 0 rows affected (1.34 sec)

mysql> ALTER TABLE e2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.90 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

You can see which partitions in table `e` contain rows by querying the `INFORMATION_SCHEMA.PARTITIONS` table, like this:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
```

```

-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0 | 1 |
| p1 | 0 |
| p2 | 0 |
| p3 | 3 |
+-----+-----+
4 rows in set (0.00 sec)

```

**Note**

For partitioned InnoDB tables, the row count given in the TABLE\_ROWS column of the INFORMATION\_SCHEMA.PARTITIONS table is only an estimated value used in SQL optimization, and is not always exact.

To exchange partition p0 in table e with table e2, you can use the ALTER TABLE statement shown here:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```

More precisely, the statement just issued causes any rows found in the partition to be swapped with those found in the table. You can observe how this has happened by querying the INFORMATION\_SCHEMA.PARTITIONS table, as before. The table row that was previously found in partition p0 is no longer present:

```

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0 | 0 |
| p1 | 0 |
| p2 | 0 |
| p3 | 3 |
+-----+-----+
4 rows in set (0.00 sec)

```

If you query table e2, you can see that the “missing” row can now be found there:

```
mysql> SELECT * FROM e2;
+----+-----+-----+
| id | fname | lname |
+----+-----+-----+
| 16 | Frank | White |
+----+-----+-----+
1 row in set (0.00 sec)
```

The table to be exchanged with the partition does not necessarily have to be empty. To demonstrate this, we first insert a new row into table e, making sure that this row is stored in partition p0 by choosing an id column value that is less than 50, and verifying this afterward by querying the PARTITIONS table:

```

mysql> INSERT INTO e VALUES (41, "Michael", "Green");
Query OK, 1 row affected (0.05 sec)

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0 | 1 |
| p1 | 0 |
| p2 | 0 |
+-----+-----+

```

```
| p3 | 3 |
+-----+
4 rows in set (0.00 sec)
```

Now we once again exchange partition `p0` with table `e2` using the same `ALTER TABLE` statement as previously:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```

The output of the following queries shows that the table row that was stored in partition `p0` and the table row that was stored in table `e2`, prior to issuing the `ALTER TABLE` statement, have now switched places:

```
mysql> SELECT * FROM e;
+----+----+----+
| id | fname | lname |
+----+----+----+
| 16 | Frank | White |
| 1669 | Jim | Smith |
| 337 | Mary | Jones |
| 2005 | Linda | Black |
+----+----+----+
4 rows in set (0.00 sec)

mysql> SELECT PARTITION_NAME, TABLE_ROWS
 -> FROM INFORMATION_SCHEMA.PARTITIONS
 -> WHERE TABLE_NAME = 'e';
+----+----+
| PARTITION_NAME | TABLE_ROWS |
+----+----+
| p0 | 1 |
| p1 | 0 |
| p2 | 0 |
| p3 | 3 |
+----+----+
4 rows in set (0.00 sec)

mysql> SELECT * FROM e2;
+----+----+----+
| id | fname | lname |
+----+----+----+
| 41 | Michael | Green |
+----+----+----+
1 row in set (0.00 sec)
```

## Nonmatching Rows

You should keep in mind that any rows found in the nonpartitioned table prior to issuing the `ALTER TABLE ... EXCHANGE PARTITION` statement must meet the conditions required for them to be stored in the target partition; otherwise, the statement fails. To see how this occurs, first insert a row into `e2` that is outside the boundaries of the partition definition for partition `p0` of table `e`. For example, insert a row with an `id` column value that is too large; then, try to exchange the table with the partition again:

```
mysql> INSERT INTO e2 VALUES (51, "Ellen", "McDonald");
Query OK, 1 row affected (0.08 sec)

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition
```

Only the `WITHOUT VALIDATION` option would permit this operation to succeed:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.02 sec)
```

When a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using `REPAIR TABLE` or `ALTER TABLE ... REPAIR PARTITION`.

## Exchanging Partitions Without Row-By-Row Validation

To avoid time consuming validation when exchanging a partition with a table that has many rows, it is possible to skip the row-by-row validation step by appending `WITHOUT VALIDATION` to the `ALTER TABLE ... EXCHANGE PARTITION` statement.

The following example compares the difference between execution times when exchanging a partition with a nonpartitioned table, with and without validation. The partitioned table (table `e`) contains two partitions of 1 million rows each. The rows in `p0` of table `e` are removed and `p0` is exchanged with a nonpartitioned table of 1 million rows. The `WITH VALIDATION` operation takes 0.74 seconds. By comparison, the `WITHOUT VALIDATION` operation takes 0.01 seconds.

```
Create a partitioned table with 1 million rows in each partition

CREATE TABLE e (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30)
)
PARTITION BY RANGE (id) (
 PARTITION p0 VALUES LESS THAN (1000001),
 PARTITION p1 VALUES LESS THAN (2000001),
);
;

SELECT COUNT(*) FROM e;
| COUNT(*) |
+-----+
| 2000000 |
+-----+
1 row in set (0.27 sec)

View the rows in each partition

SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0 | 1000000 |
| p1 | 1000000 |
+-----+-----+
2 rows in set (0.00 sec)

Create a nonpartitioned table of the same structure and populate it with 1 million rows

CREATE TABLE e2 (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30)
);
;

mysql> SELECT COUNT(*) FROM e2;
+-----+
| COUNT(*) |
+-----+
| 1000000 |
+-----+
1 row in set (0.24 sec)

Create another nonpartitioned table of the same structure and populate it with 1 million rows

CREATE TABLE e3 (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30)
);
;

mysql> SELECT COUNT(*) FROM e3;
+-----+
| COUNT(*) |
+-----+
```

```

| 1000000 |
+-----+
1 row in set (0.25 sec)

Drop the rows from p0 of table e

mysql> DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)

Confirm that there are no rows in partition p0

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0 | 0 |
| p1 | 1000000 |
+-----+-----+
2 rows in set (0.00 sec)

Exchange partition p0 of table e with the table e2 'WITH VALIDATION'

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITH VALIDATION;
Query OK, 0 rows affected (0.74 sec)

Confirm that the partition was exchanged with table e2

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0 | 1000000 |
| p1 | 1000000 |
+-----+-----+
2 rows in set (0.00 sec)

Once again, drop the rows from p0 of table e

mysql> DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)

Confirm that there are no rows in partition p0

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0 | 0 |
| p1 | 1000000 |
+-----+-----+
2 rows in set (0.00 sec)

Exchange partition p0 of table e with the table e3 'WITHOUT VALIDATION'

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e3 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.01 sec)

Confirm that the partition was exchanged with table e3

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0 | 1000000 |
| p1 | 1000000 |
+-----+-----+
2 rows in set (0.00 sec)

```

If a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using `REPAIR TABLE` or `ALTER TABLE ... REPAIR PARTITION`.

## Exchanging a Subpartition with a Nonpartitioned Table

You can also exchange a subpartition of a subpartitioned table (see [Section 22.2.6, “Subpartitioning”](#)) with a nonpartitioned table using an `ALTER TABLE ... EXCHANGE PARTITION` statement. In the following example, we first create a table `es` that is partitioned by `RANGE` and subpartitioned by `KEY`, populate this table as we did table `e`, and then create an empty, nonpartitioned copy `es2` of the table, as shown here:

```
mysql> CREATE TABLE es (
-> id INT NOT NULL,
-> fname VARCHAR(30),
-> lname VARCHAR(30)
->)
-> PARTITION BY RANGE (id)
-> SUBPARTITION BY KEY (lname)
-> SUBPARTITIONS 2 (
-> PARTITION p0 VALUES LESS THAN (50),
-> PARTITION p1 VALUES LESS THAN (100),
-> PARTITION p2 VALUES LESS THAN (150),
-> PARTITION p3 VALUES LESS THAN (MAXVALUE)
->);
Query OK, 0 rows affected (2.76 sec)

mysql> INSERT INTO es VALUES
-> (1669, "Jim", "Smith"),
-> (337, "Mary", "Jones"),
-> (16, "Frank", "White"),
-> (2005, "Linda", "Black");
Query OK, 4 rows affected (0.04 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> CREATE TABLE es2 LIKE es;
Query OK, 0 rows affected (1.27 sec)

mysql> ALTER TABLE es2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.70 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

Although we did not explicitly name any of the subpartitions when creating table `es`, we can obtain generated names for these by including the `SUBPARTITION_NAME` of the `PARTITIONS` table from `INFORMATION_SCHEMA` when selecting from that table, as shown here:

```
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'es';
+-----+-----+-----+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p0 | p0sp0 | 1 |
| p0 | p0sp1 | 0 |
| p1 | p1sp0 | 0 |
| p1 | p1sp1 | 0 |
| p2 | p2sp0 | 0 |
| p2 | p2sp1 | 0 |
| p3 | p3sp0 | 3 |
| p3 | p3sp1 | 0 |
+-----+-----+-----+
8 rows in set (0.00 sec)
```

The following `ALTER TABLE` statement exchanges subpartition `p3sp0` table `es` with the nonpartitioned table `es2`:

```
mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es2;
Query OK, 0 rows affected (0.29 sec)
```

You can verify that the rows were exchanged by issuing the following queries:

```
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
```

```
--> WHERE TABLE_NAME = 'es';
+-----+-----+-----+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p0 | p0sp0 | 1 |
| p0 | p0sp1 | 0 |
| p1 | p1sp0 | 0 |
| p1 | p1sp1 | 0 |
| p2 | p2sp0 | 0 |
| p2 | p2sp1 | 0 |
| p3 | p3sp0 | 0 |
| p3 | p3sp1 | 0 |
+-----+-----+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM es2;
+----+----+----+
| id | fname | lname |
+----+----+----+
| 1669 | Jim | Smith |
| 337 | Mary | Jones |
| 2005 | Linda | Black |
+----+----+----+
3 rows in set (0.00 sec)
```

If a table is subpartitioned, you can exchange only a subpartition of the table—not an entire partition—with an unpartitioned table, as shown here:

```
mysql> ALTER TABLE es EXCHANGE PARTITION p3 WITH TABLE es2;
ERROR 1704 (HY000): Subpartitioned table, use subpartition instead of partition
```

The comparison of table structures used by MySQL is very strict. The number, order, names, and types of columns and indexes of the partitioned table and the nonpartitioned table must match exactly. In addition, both tables must use the same storage engine:

```
mysql> CREATE TABLE es3 LIKE e;
Query OK, 0 rows affected (1.31 sec)

mysql> ALTER TABLE es3 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.53 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE es3\G
***** 1. row *****
 Table: es3
Create Table: CREATE TABLE `es3` (
 `id` int(11) NOT NULL,
 `fname` varchar(30) DEFAULT NULL,
 `lname` varchar(30) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
1 row in set (0.00 sec)

mysql> ALTER TABLE es3 ENGINE = MyISAM;
Query OK, 0 rows affected (0.15 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es3;
ERROR 1497 (HY000): The mix of handlers in the partitions is not allowed in this version of MySQL
```

## 22.3.4 Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out using SQL statements intended for such purposes on partitioned tables in MySQL 5.7.

Table maintenance of partitioned tables can be accomplished using the statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE`, which are supported for partitioned tables.

You can use a number of extensions to `ALTER TABLE` for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

Example:

```
ALTER TABLE t1 REBUILD PARTITION p0, p1;
```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`, or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

Example:

```
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
```

Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

Some MySQL storage engines, including `InnoDB`, do not support per-partition optimization; in these cases, `ALTER TABLE ... OPTIMIZE PARTITION` analyzes and rebuilds the entire table, and causes an appropriate warning to be issued. (Bug #11751825, Bug #42822) Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead, to avoid this issue.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

Example:

```
ALTER TABLE t1 ANALYZE PARTITION p3;
```

- **Repairing partitions.** This repairs corrupted partitions.

Example:

```
ALTER TABLE t1 REPAIR PARTITION p0,p1;
```

Normally, `REPAIR PARTITION` fails when the partition contains duplicate key errors. In MySQL 5.7.2 and later, you can use `ALTER IGNORE TABLE` with this option, in which case all rows that cannot be moved due to the presence of duplicate keys are removed from the partition (Bug #16900947).

- **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with nonpartitioned tables.

Example:

```
ALTER TABLE trb3 CHECK PARTITION p1;
```

This command tells you if the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

Normally, `CHECK PARTITION` fails when the partition contains duplicate key errors. In MySQL 5.7.2 and later, you can use `ALTER IGNORE TABLE` with this option, in which case the statement returns the contents of each row in the partition where a duplicate key violation is found. Only the values for the columns in the partitioning expression for the table are reported. (Bug #16900947)

Each of the statements in the list just shown also supports the keyword `ALL` in place of the list of partition names. Using `ALL` causes the statement to act on all partitions in the table.

The use of `mysqlcheck` and `myisamchk` is not supported with partitioned tables.

In MySQL 5.7, you can also truncate partitions using `ALTER TABLE ... TRUNCATE PARTITION`. This statement can be used to delete all rows from one or more partitions in much the same way that `TRUNCATE TABLE` deletes all rows from a table.

`ALTER TABLE ... TRUNCATE PARTITION ALL` truncates all partitions in the table.

Prior to MySQL 5.7.2, `ANALYZE`, `CHECK`, `OPTIMIZE`, `REBUILD`, `REPAIR`, and `TRUNCATE` operations were not permitted on subpartitions (Bug #14028340, Bug #65184).

## 22.3.5 Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. Methods of obtaining such information include the following:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
***** 1. row *****
 Table: trb3
Create Table: CREATE TABLE `trb3` (
 `id` int(11) default NULL,
 `name` varchar(50) default NULL,
 `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
 PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
 PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
 PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.00 sec)
```

The output from `SHOW TABLE STATUS` for partitioned tables is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. The `Engine` column contains the name of the storage engine used by all partitions of the table. (See Section 13.7.5.36, “`SHOW TABLE STATUS Statement`”, for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See Section 24.3.16, “The `INFORMATION_SCHEMA PARTITIONS Table`”.

It is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN`. The `partitions` column in the `EXPLAIN` output lists the partitions from which records would be matched by the query.

Suppose that you have a table `trb1` created and populated as follows:

```
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
 PARTITION BY RANGE(id)
 (
 PARTITION p0 VALUES LESS THAN (3),
 PARTITION p1 VALUES LESS THAN (7),
 PARTITION p2 VALUES LESS THAN (9),
 PARTITION p3 VALUES LESS THAN (11)
);
INSERT INTO trb1 VALUES
```

## Obtaining Information About Partitions

```
(1, 'desk organiser', '2003-10-15'),
(2, 'CD player', '1993-11-05'),
(3, 'TV set', '1996-03-10'),
(4, 'bookcase', '1982-01-10'),
(5, 'exercise bike', '2004-05-09'),
(6, 'sofa', '1987-06-05'),
(7, 'popcorn maker', '2001-11-22'),
(8, 'aquarium', '1992-08-04'),
(9, 'study desk', '1984-09-16'),
(10, 'lava lamp', '1998-12-25');
```

You can see which partitions are used in a query such as `SELECT * FROM trbl;`, as shown here:

```
mysql> EXPLAIN SELECT * FROM trbl\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: trbl
 partitions: p0,p1,p2,p3
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 10
 Extra: Using filesort
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```
mysql> EXPLAIN SELECT * FROM trbl WHERE id < 5\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: trbl
 partitions: p0,p1
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 10
 Extra: Using where
```

`EXPLAIN` also provides information about keys used and possible keys:

```
mysql> ALTER TABLE trbl ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10 Duplicates: 0 Warnings: 0

mysql> EXPLAIN SELECT * FROM trbl WHERE id < 5\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: trbl
 partitions: p0,p1
 type: range
possible_keys: PRIMARY
 key: PRIMARY
 key_len: 4
 ref: NULL
 rows: 7
 Extra: Using where
```

If `EXPLAIN PARTITIONS` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

The `rows` column of `EXPLAIN` output displays the total number of rows in the table.

See also Section 13.8.2, “[EXPLAIN Statement](#)”.

## 22.4 Partition Pruning

This section discusses an optimization known as *partition pruning*. The core concept behind partition pruning is relatively simple, and can be described as “Do not scan partitions where there can be no matching values”. Suppose that you have a partitioned table `t1` defined by this statement:

```
CREATE TABLE t1 (
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 region_code TINYINT UNSIGNED NOT NULL,
 dob DATE NOT NULL
)
PARTITION BY RANGE(region_code) (
 PARTITION p0 VALUES LESS THAN (64),
 PARTITION p1 VALUES LESS THAN (128),
 PARTITION p2 VALUES LESS THAN (192),
 PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Consider the case where you wish to obtain results from a `SELECT` statement such as this one:

```
SELECT fname, lname, region_code, dob
 FROM t1
 WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned are in either of the partitions `p0` or `p3`; that is, we need to search only in partitions `p1` and `p2` to find matching rows. By doing so, it is possible to expend much less time and effort in finding matching rows than would be required to scan all partitions in the table. This “cutting away” of unneeded partitions is known as *pruning*. When the optimizer can make use of partition pruning in performing this query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

### Note

When pruning is performed on a partitioned `MyISAM` table, all partitions are opened, whether or not they are examined, due to the design of the `MyISAM` storage engine. This means that you must have a sufficient number of file descriptors available to cover all partitions of the table. See [MyISAM and partition file descriptor usage](#).

This limitation does not apply to partitioned tables using other MySQL storage engines such as `InnoDB`.

The optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following two cases:

- `partition_column = constant`
- `partition_column IN (constant1, constant2, ..., constantN)`

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including `<`, `>`, `<=`, `>=`, and `<>`. Some queries using `BETWEEN` in the `WHERE` clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

MySQL can apply partition pruning to `SELECT`, `DELETE`, and `UPDATE` statements. An `INSERT` statement also accesses only one partition per inserted row; this is true even for a table that is partitioned by `HASH` or `KEY` although this is not currently shown in the output of `EXPLAIN`.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the `WHERE` clause can be converted to `WHERE region_code IN (126, 127, 128, 129)`. Then the optimizer can determine that the first two values in the list are found in partition `p1`, the remaining two values in partition `p2`, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

The optimizer can also perform pruning for `WHERE` conditions that involve comparisons of the preceding types on multiple columns for tables that use `RANGE COLUMNS` or `LIST COLUMNS` partitioning.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a `DATE` or `DATETIME` column when the partitioning expression uses the `YEAR()` or `TO_DAYS()` function. In addition, in MySQL 5.7, pruning can be applied for such tables when the partitioning expression uses the `TO_SECONDS()` function.

Suppose that table `t2`, defined as shown here, is partitioned on a `DATE` column:

```
CREATE TABLE t2 (
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 region_code TINYINT UNSIGNED NOT NULL,
 dob DATE NOT NULL
)
PARTITION BY RANGE(YEAR(dob)) (
 PARTITION d0 VALUES LESS THAN (1970),
 PARTITION d1 VALUES LESS THAN (1975),
 PARTITION d2 VALUES LESS THAN (1980),
 PARTITION d3 VALUES LESS THAN (1985),
 PARTITION d4 VALUES LESS THAN (1990),
 PARTITION d5 VALUES LESS THAN (2000),
 PARTITION d6 VALUES LESS THAN (2005),
 PARTITION d7 VALUES LESS THAN MAXVALUE
);
```

The following statements using `t2` can make use of partition pruning:

```
SELECT * FROM t2 WHERE dob = '1982-06-23';

UPDATE t2 SET region_code = 8 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';

DELETE FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last statement, the optimizer can also act as follows:

1. *Find the partition containing the low end of the range.*

`YEAR('1984-06-21')` yields the value `1984`, which is found in partition `d3`.

2. *Find the partition containing the high end of the range.*

`YEAR('1999-06-21')` evaluates to `1999`, which is found in partition `d5`.

3. *Scan only these two partitions and any partitions that may lie between them.*

In this case, this means that only partitions `d3`, `d4`, and `d5` are scanned. The remaining partitions may be safely ignored (and are ignored).

### Important

Invalid `DATE` and `DATETIME` values referenced in the `WHERE` condition of a statement against a partitioned table are treated as `NULL`. This means that a query such as `SELECT * FROM partitioned_table WHERE date_column < '2008-12-00'` does not return any values (see Bug #40972).

So far, we have looked only at examples using `RANGE` partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by `LIST`, where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```
CREATE TABLE t3 (
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 region_code TINYINT UNSIGNED NOT NULL,
 dob DATE NOT NULL
)
PARTITION BY LIST(region_code) (
 PARTITION r0 VALUES IN (1, 3),
 PARTITION r1 VALUES IN (2, 5, 8),
 PARTITION r2 VALUES IN (4, 9),
 PARTITION r3 VALUES IN (6, 7, 10)
);
```

For a statement such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by `HASH` or `[LINEAR] KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 region_code TINYINT UNSIGNED NOT NULL,
 dob DATE NOT NULL
)
PARTITION BY KEY(region_code)
PARTITIONS 8;
```

A statement that compares a column value with a constant can be pruned:

```
UPDATE t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

### Important

This optimization is used only if the range size is smaller than the number of partitions. Consider this statement:

```
DELETE FROM t4 WHERE region_code BETWEEN 4 AND 12;
```

The range in the `WHERE` clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the `DELETE` cannot be pruned.

When a table is partitioned by `HASH` or `[LINEAR] KEY`, pruning can be used only on integer columns. For example, this statement cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

Prior to MySQL 5.7.1, partition pruning was disabled for all tables using a storage engine that provides automatic partitioning, such as the `NDB` storage engine used by NDB Cluster. (Bug #14672885) Beginning with MySQL 5.7.1, such tables can be pruned if they are explicitly partitioned. (Bug #14827952)

## 22.5 Partition Selection

MySQL 5.7 supports explicit selection of partitions and subpartitions that, when executing a statement, should be checked for rows matching a given `WHERE` condition. Partition selection is similar to partition pruning, in that only specific partitions are checked for matches, but differs in two key respects:

1. The partitions to be checked are specified by the issuer of the statement, unlike partition pruning, which is automatic.
2. Whereas partition pruning applies only to queries, explicit selection of partitions is supported for both queries and a number of DML statements.

SQL statements supporting explicit partition selection are listed here:

- `SELECT`
- `DELETE`
- `INSERT`
- `REPLACE`
- `UPDATE`
- `LOAD DATA`.
- `LOAD XML`.

The remainder of this section discusses explicit partition selection as it applies generally to the statements just listed, and provides some examples.

Explicit partition selection is implemented using a `PARTITION` option. For all supported statements, this option uses the syntax shown here:

```
PARTITION (partition_names)
partition_names:
 partition_name, ...
```

This option always follows the name of the table to which the partition or partitions belong. `partition_names` is a comma-separated list of partitions or subpartitions to be used. Each name in this list must be the name of an existing partition or subpartition of the specified table; if any of the partitions or subpartitions are not found, the statement fails with an error (`partition 'partition_name' doesn't exist`). Partitions and subpartitions named in `partition_names` may be listed in any order, and may overlap.

When the `PARTITION` option is used, only the partitions and subpartitions listed are checked for matching rows. This option can be used in a `SELECT` statement to determine which rows belong to a given partition. Consider a partitioned table named `employees`, created and populated using the statements shown here:

```
SET @@SQL_MODE = '';
CREATE TABLE employees (
 id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 fname VARCHAR(25) NOT NULL,
```

```

 lname VARCHAR(25) NOT NULL,
 store_id INT NOT NULL,
 department_id INT NOT NULL
)
 PARTITION BY RANGE(id) (
 PARTITION p0 VALUES LESS THAN (5),
 PARTITION p1 VALUES LESS THAN (10),
 PARTITION p2 VALUES LESS THAN (15),
 PARTITION p3 VALUES LESS THAN MAXVALUE
);
INSERT INTO employees VALUES
 ('', 'Bob', 'Taylor', 3, 2), ('', 'Frank', 'Williams', 1, 2),
 ('', 'Ellen', 'Johnson', 3, 4), ('', 'Jim', 'Smith', 2, 4),
 ('', 'Mary', 'Jones', 1, 1), ('', 'Linda', 'Black', 2, 3),
 ('', 'Ed', 'Jones', 2, 1), ('', 'June', 'Wilson', 3, 1),
 ('', 'Andy', 'Smith', 1, 3), ('', 'Lou', 'Waters', 2, 4),
 ('', 'Jill', 'Stone', 1, 4), ('', 'Roger', 'White', 3, 2),
 ('', 'Howard', 'Andrews', 1, 2), ('', 'Fred', 'Goldberg', 3, 3),
 ('', 'Barbara', 'Brown', 2, 3), ('', 'Alice', 'Rogers', 2, 2),
 ('', 'Mark', 'Morgan', 3, 3), ('', 'Karen', 'Cole', 3, 2);

```

You can see which rows are stored in partition `p1` like this:

```

mysql> SELECT * FROM employees PARTITION (p1);
+----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+----+-----+-----+-----+-----+
| 5 | Mary | Jones | 1 | 1 |
| 6 | Linda | Black | 2 | 3 |
| 7 | Ed | Jones | 2 | 1 |
| 8 | June | Wilson | 3 | 1 |
| 9 | Andy | Smith | 1 | 3 |
+----+-----+-----+-----+
5 rows in set (0.00 sec)

```

The result is the same as obtained by the query `SELECT * FROM employees WHERE id BETWEEN 5 AND 9.`

To obtain rows from multiple partitions, supply their names as a comma-delimited list. For example, `SELECT * FROM employees PARTITION (p1, p2)` returns all rows from partitions `p1` and `p2` while excluding rows from the remaining partitions.

Any valid query against a partitioned table can be rewritten with a `PARTITION` option to restrict the result to one or more desired partitions. You can use `WHERE` conditions, `ORDER BY` and `LIMIT` options, and so on. You can also use aggregate functions with `HAVING` and `GROUP BY` options. Each of the following queries produces a valid result when run on the `employees` table as previously defined:

```

mysql> SELECT * FROM employees PARTITION (p0, p2)
 -> WHERE lname LIKE 'S%';
+----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+----+-----+-----+-----+
| 4 | Jim | Smith | 2 | 4 |
| 11 | Jill | Stone | 1 | 4 |
+----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT id, CONCAT(fname, ' ', lname) AS name
 -> FROM employees PARTITION (p0) ORDER BY lname;
+----+-----+
| id | name |
+----+-----+
| 3 | Ellen Johnson |
| 4 | Jim Smith |
| 1 | Bob Taylor |
| 2 | Frank Williams |
+----+-----+
4 rows in set (0.06 sec)

```

## Partition Selection

```
mysql> SELECT store_id, COUNT(department_id) AS c
 -> FROM employees PARTITION (p1,p2,p3)
 -> GROUP BY store_id HAVING c > 4;
+---+-----+
| c | store_id |
+---+-----+
| 5 | 2 |
| 5 | 3 |
+---+-----+
2 rows in set (0.00 sec)
```

Statements using partition selection can be employed with tables using any of the partitioning types supported in MySQL 5.7. When a table is created using [LINEAR] HASH or [LINEAR] KEY partitioning and the names of the partitions are not specified, MySQL automatically names the partitions  $p_0, p_1, p_2, \dots, p_{N-1}$ , where  $N$  is the number of partitions. For subpartitions not explicitly named, MySQL assigns automatically to the subpartitions in each partition  $p_X$  the names  $p_{Xsp0}, p_{Xsp1}, p_{Xsp2}, \dots, p_{XspM-1}$ , where  $M$  is the number of subpartitions. When executing against this table a `SELECT` (or other SQL statement for which explicit partition selection is allowed), you can use these generated names in a `PARTITION` option, as shown here:

```
mysql> CREATE TABLE employees_sub (
 -> id INT NOT NULL AUTO_INCREMENT,
 -> fname VARCHAR(25) NOT NULL,
 -> lname VARCHAR(25) NOT NULL,
 -> store_id INT NOT NULL,
 -> department_id INT NOT NULL,
 -> PRIMARY KEY pk (id, lname)
 ->)
 -> PARTITION BY RANGE(id)
 -> SUBPARTITION BY KEY (lname)
 -> SUBPARTITIONS 2 (
 -> PARTITION p0 VALUES LESS THAN (5),
 -> PARTITION p1 VALUES LESS THAN (10),
 -> PARTITION p2 VALUES LESS THAN (15),
 -> PARTITION p3 VALUES LESS THAN MAXVALUE
 ->);
Query OK, 0 rows affected (1.14 sec)

mysql> INSERT INTO employees_sub # re-use data in employees table
 -> SELECT * FROM employees;
Query OK, 18 rows affected (0.09 sec)
Records: 18 Duplicates: 0 Warnings: 0

mysql> SELECT id, CONCAT(fname, ' ', lname) AS name
 -> FROM employees_sub PARTITION (p2sp1);
+---+-----+
| id | name |
+---+-----+
| 10 | Lou Waters |
| 14 | Fred Goldberg |
+---+-----+
2 rows in set (0.00 sec)
```

You may also use a `PARTITION` option in the `SELECT` portion of an `INSERT ... SELECT` statement, as shown here:

```
mysql> CREATE TABLE employees_copy LIKE employees;
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO employees_copy
 -> SELECT * FROM employees PARTITION (p2);
Query OK, 5 rows affected (0.04 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM employees_copy;
+---+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+---+-----+-----+-----+
| 10 | Lou | Waters | 2 | 4 |
| 11 | Jill | Stone | 1 | 4 |
+---+-----+-----+-----+
```

```

| 12 | Roger | White | 3 | 2 |
| 13 | Howard | Andrews | 1 | 2 |
| 14 | Fred | Goldberg | 3 | 3 |
+----+-----+-----+-----+
5 rows in set (0.00 sec)

```

Partition selection can also be used with joins. Suppose we create and populate two tables using the statements shown here:

```

CREATE TABLE stores (
 id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 city VARCHAR(30) NOT NULL
)
PARTITION BY HASH(id)
PARTITIONS 2;

INSERT INTO stores VALUES
 ('', 'Nambucca'), ('', 'Uranga'),
 ('', 'Bellingen'), ('', 'Grafton');

CREATE TABLE departments (
 id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 name VARCHAR(30) NOT NULL
)
PARTITION BY KEY(id)
PARTITIONS 2;

INSERT INTO departments VALUES
 ('', 'Sales'), ('', 'Customer Service'),
 ('', 'Delivery'), ('', 'Accounting');

```

You can explicitly select partitions (or subpartitions, or both) from any or all of the tables in a join. (The `PARTITION` option used to select partitions from a given table immediately follows the name of the table, before all other options, including any table alias.) For example, the following query gets the name, employee ID, department, and city of all employees who work in the Sales or Delivery department (partition `p1` of the `departments` table) at the stores in either of the cities of Nambucca and Bellingen (partition `p0` of the `stores` table):

```

mysql> SELECT
 -> e.id AS 'Employee ID', CONCAT(e.fname, ' ', e.lname) AS Name,
 -> s.city AS City, d.name AS department
 -> FROM employees AS e
 -> JOIN stores PARTITION (p1) AS s ON e.store_id=s.id
 -> JOIN departments PARTITION (p0) AS d ON e.department_id=d.id
 -> ORDER BY e.lname;
+-----+-----+-----+-----+
| Employee ID | Name | City | department |
+-----+-----+-----+-----+
| 14 | Fred Goldberg | Bellingen | Delivery |
| 5 | Mary Jones | Nambucca | Sales |
| 17 | Mark Morgan | Bellingen | Delivery |
| 9 | Andy Smith | Nambucca | Delivery |
| 8 | June Wilson | Bellingen | Sales |
+-----+-----+-----+-----+
5 rows in set (0.00 sec)

```

For general information about joins in MySQL, see [Section 13.2.9.2, “JOIN Clause”](#).

When the `PARTITION` option is used with `DELETE` statements, only those partitions (and subpartitions, if any) listed with the option are checked for rows to be deleted. Any other partitions are ignored, as shown here:

```

mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+
| 4 | Jim | Smith | 2 | 4 |
| 8 | June | Wilson | 3 | 1 |
| 11 | Jill | Stone | 1 | 4 |
+-----+-----+-----+-----+

```

## Partition Selection

```
3 rows in set (0.00 sec)

mysql> DELETE FROM employees PARTITION (p0, p1)
 -> WHERE fname LIKE 'j%';
Query OK, 2 rows affected (0.09 sec)

mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
+----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+----+-----+-----+-----+
| 11 | Jill | Stone | 1 | 4 |
+----+-----+-----+-----+
1 row in set (0.00 sec)
```

Only the two rows in partitions `p0` and `p1` matching the `WHERE` condition were deleted. As you can see from the result when the `SELECT` is run a second time, there remains a row in the table matching the `WHERE` condition, but residing in a different partition (`p2`).

`UPDATE` statements using explicit partition selection behave in the same way; only rows in the partitions referenced by the `PARTITION` option are considered when determining the rows to be updated, as can be seen by executing the following statements:

```
mysql> UPDATE employees PARTITION (p0)
 -> SET store_id = 2 WHERE fname = 'Jill';
Query OK, 0 rows affected (0.00 sec)
Rows matched: 0 Changed: 0 Warnings: 0

mysql> SELECT * FROM employees WHERE fname = 'Jill';
+----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+----+-----+-----+-----+
| 11 | Jill | Stone | 1 | 4 |
+----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> UPDATE employees PARTITION (p2)
 -> SET store_id = 2 WHERE fname = 'Jill';
Query OK, 1 row affected (0.09 sec)
Rows matched: 1 Changed: 1 Warnings: 0

mysql> SELECT * FROM employees WHERE fname = 'Jill';
+----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+----+-----+-----+-----+
| 11 | Jill | Stone | 2 | 4 |
+----+-----+-----+-----+
1 row in set (0.00 sec)
```

In the same way, when `PARTITION` is used with `DELETE`, only rows in the partition or partitions named in the partition list are checked for deletion.

For statements that insert rows, the behavior differs in that failure to find a suitable partition causes the statement to fail. This is true for both `INSERT` and `REPLACE` statements, as shown here:

```
mysql> INSERT INTO employees PARTITION (p2) VALUES (20, 'Jan', 'Jones', 1, 3);
ERROR 1729 (HY000): Found a row not matching the given partition set
mysql> INSERT INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 1, 3);
Query OK, 1 row affected (0.07 sec)

mysql> REPLACE INTO employees PARTITION (p0) VALUES (20, 'Jan', 'Jones', 3, 2);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> REPLACE INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 3, 2);
Query OK, 2 rows affected (0.09 sec)
```

For statements that write multiple rows to a partitioned table that uses the `InnoDB` storage engine: If any row in the list following `VALUES` cannot be written to one of the partitions specified in the `partition_names` list, the entire statement fails and no rows are written. This is shown for `INSERT` statements in the following example, reusing the `employees` table created previously:

```

mysql> ALTER TABLE employees
-> REORGANIZE PARTITION p3 INTO (
-> PARTITION p3 VALUES LESS THAN (20),
-> PARTITION p4 VALUES LESS THAN (25),
-> PARTITION p5 VALUES LESS THAN MAXVALUE
->);
Query OK, 6 rows affected (2.09 sec)
Records: 6 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE employees\G
***** 1. row ****
Table: employees
Create Table: CREATE TABLE `employees` (
 `id` int(11) NOT NULL AUTO_INCREMENT,
 `fname` varchar(25) NOT NULL,
 `lname` varchar(25) NOT NULL,
 `store_id` int(11) NOT NULL,
 `department_id` int(11) NOT NULL,
 PRIMARY KEY (`id`)
) ENGINE=InnoDB AUTO_INCREMENT=27 DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE (id)
(PARTITION p0 VALUES LESS THAN (5) ENGINE = InnoDB,
 PARTITION p1 VALUES LESS THAN (10) ENGINE = InnoDB,
 PARTITION p2 VALUES LESS THAN (15) ENGINE = InnoDB,
 PARTITION p3 VALUES LESS THAN (20) ENGINE = InnoDB,
 PARTITION p4 VALUES LESS THAN (25) ENGINE = InnoDB,
 PARTITION p5 VALUES LESS THAN MAXVALUE ENGINE = InnoDB) */
1 row in set (0.00 sec)

mysql> INSERT INTO employees PARTITION (p3, p4) VALUES
-> (24, 'Tim', 'Greene', 3, 1), (26, 'Linda', 'Mills', 2, 1);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> INSERT INTO employees PARTITION (p3, p4, p5) VALUES
-> (24, 'Tim', 'Greene', 3, 1), (26, 'Linda', 'Mills', 2, 1);
Query OK, 2 rows affected (0.06 sec)
Records: 2 Duplicates: 0 Warnings: 0

```

The preceding is true for both `INSERT` statements and `REPLACE` statements that write multiple rows.

In MySQL 5.7.1 and later, partition selection is disabled for tables employing a storage engine that supplies automatic partitioning, such as `NDB`. (Bug #14827952)

## 22.6 Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support.

**Prohibited constructs.** The following constructs are not permitted in partitioning expressions:

- Stored procedures, stored functions, UDFs, or plugins.
- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see [Section 22.6.3, “Partitioning Limitations Relating to Functions”](#).

**Arithmetic and logical operators.** Use of the arithmetic operators `+`, `-`, and `*` is permitted in partitioning expressions. However, the result must be an integer value or `NULL` (except in the case of `[LINEAR] KEY` partitioning, as discussed elsewhere in this chapter; see [Section 22.2, “Partitioning Types”](#), for more information).

The `DIV` operator is also supported, and the `/` operator is not permitted. (Bug #30188, Bug #33182)

The bit operators `|`, `&`, `^`, `<<`, `>>`, and `~` are not permitted in partitioning expressions.

**HANDLER statements.** Previously, the `HANDLER` statement was not supported with partitioned tables. This limitation is removed beginning with MySQL 5.7.1.

**Server SQL mode.** Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in [Section 5.1.10, “Server SQL Modes”](#), the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, *it is strongly recommended that you never change the server SQL mode after creating partitioned tables*.

**Examples.** The following examples illustrate some changes in behavior of partitioned tables due to a change in the server SQL mode:

1. **Error handling.** Suppose that you create a partitioned table whose partitioning expression is one such as `column DIV 0` or `column MOD 0`, as shown here:

```
mysql> CREATE TABLE tn (c1 INT)
-> PARTITION BY LIST(1 DIV c1) (
-> PARTITION p0 VALUES IN (NULL),
-> PARTITION p1 VALUES IN (1)
->);
Query OK, 0 rows affected (0.05 sec)
```

The default behavior for MySQL is to return `NULL` for the result of a division by zero, without producing any errors:

```
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| |
+-----+
1 row in set (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

However, changing the server SQL mode to treat division by zero as an error and to enforce strict error handling causes the same `INSERT` statement to fail, as shown here:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
ERROR 1365 (22012): Division by 0
```

2. **Table accessibility.** Sometimes a change in the server SQL mode can make partitioned tables unusable. The following `CREATE TABLE` statement can be executed successfully only if the `NO_UNSIGNED_SUBTRACTION` mode is in effect:

```
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) (
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
->);
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

```

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| NO_UNSIGNED_SUBTRACTION |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
 -> PARTITION BY RANGE(c1 - 10) (
 -> PARTITION p0 VALUES LESS THAN (-5),
 -> PARTITION p1 VALUES LESS THAN (0),
 -> PARTITION p2 VALUES LESS THAN (5),
 -> PARTITION p3 VALUES LESS THAN (10),
 -> PARTITION p4 VALUES LESS THAN (MAXVALUE)
 ->);
Query OK, 0 rows affected (0.05 sec)

```

If you remove the `NO_UNSIGNED_SUBTRACTION` server SQL mode after creating `tu`, you may no longer be able to access this table:

```

mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain
mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain

```

See also [Section 5.1.10, “Server SQL Modes”](#).

Server SQL modes also impact replication of partitioned tables. Disparate SQL modes on source and replica can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the source's and replica's copies of a given table, and may even cause inserts into partitioned tables that succeed on the source to fail on the replica. For best results, you should always use the same server SQL mode on the source and on the replica.

**Performance considerations.** Some effects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITION`, or `REMOVE PARTITIONING`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` is enabled and that `open_files_limit` is set properly. For partitioned tables using the `MyISAM` storage engine, increasing `myisam_max_sort_file_size` may improve performance; partitioning and repartitioning operations involving `InnoDB` tables may be made more efficient by enabling `innodb_file_per_table`.

See also [Maximum number of partitions](#).

- **MyISAM and partition file descriptor usage.**

For a partitioned `MyISAM` table, MySQL uses 2 file descriptors for each partition, for each such table that is open. This means that you need many more file descriptors to perform operations on a partitioned `MyISAM` table than on a table which is identical to it except that the latter table is not partitioned, particularly when performing `ALTER TABLE` operations.

Assume a `MyISAM` table `t` with 100 partitions, such as the table created by this SQL statement:

```

CREATE TABLE t (c1 VARCHAR(50))
PARTITION BY KEY (c1) PARTITIONS 100

```

```
ENGINE=MYISAM;
```

### Note

For brevity, we use `KEY` partitioning for the table shown in this example, but file descriptor usage as described here applies to all partitioned `MyISAM` tables, regardless of the type of partitioning that is employed. Partitioned tables using other storage engines such as `InnoDB` are not affected by this issue.

Now assume that you wish to repartition `t` so that it has 101 partitions, using the statement shown here:

```
ALTER TABLE t PARTITION BY KEY (c1) PARTITIONS 101;
```

To process this `ALTER TABLE` statement, MySQL uses 402 file descriptors—that is, two for each of the 100 original partitions, plus two for each of the 101 new partitions. This is because all partitions (old and new) must be opened concurrently during the reorganization of the table data. It is recommended that, if you expect to perform such operations, you should make sure that the `open_files_limit` system variable is not set too low to accommodate them.

- **Table locks.** Generally, the process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending `INSERT` and `UPDATE` operations are performed as soon as the partitioning operation has completed. For `InnoDB`-specific exceptions to this limitation, see [Partitioning Operations](#).
- **Storage engine.** Partitioning operations, queries, and update operations generally tend to be faster with `MyISAM` tables than with `InnoDB` or `NDB` tables.
- **Indexes; partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of *partition pruning* can improve performance dramatically. See [Section 22.4, “Partition Pruning”](#), for more information.

Previously, index condition pushdown was not supported for partitioned tables. This limitation was removed in MySQL 5.7.3. See [Section 8.2.1.5, “Index Condition Pushdown Optimization”](#).

- **Performance with LOAD DATA.** In MySQL 5.7, `LOAD DATA` uses buffering to improve performance. You should be aware that the buffer uses 130 KB memory per partition to achieve this.

### Maximum number of partitions.

The maximum possible number of partitions for a given table not using the `NDB` storage engine is 8192. This number includes subpartitions.

The maximum possible number of user-defined partitions for a table using the `NDB` storage engine is determined according to the version of the NDB Cluster software being used, the number of data nodes, and other factors. See [NDB and user-defined partitioning](#), for more information.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as `Got error ... from storage engine: Out of resources when opening file`, you may be able to address the issue by increasing the value of the `open_files_limit` system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see [Section B.3.2.16, “File Not Found and Similar Errors”](#), for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also [File system operations](#).

### Query cache not supported.

The query cache is not supported for partitioned tables, and is automatically disabled for queries involving partitioned tables. The query cache cannot be enabled for such queries.

**Per-partition key caches.**

In MySQL 5.7, key caches are supported for partitioned MyISAM tables, using the `CACHE INDEX` and `LOAD INDEX INTO CACHE` statements. Key caches may be defined for one, several, or all partitions, and indexes for one, several, or all partitions may be preloaded into key caches.

**Foreign keys not supported for partitioned InnoDB tables.**

Partitioned tables using the InnoDB storage engine do not support foreign keys. More specifically, this means that the following two statements are true:

1. No definition of an InnoDB table employing user-defined partitioning may contain foreign key references; no InnoDB table whose definition contains foreign key references may be partitioned.
2. No InnoDB table definition may contain a foreign key reference to a user-partitioned table; no InnoDB table with user-defined partitioning may contain columns referenced by foreign keys.

The scope of the restrictions just listed includes all tables that use the InnoDB storage engine. `CREATE TABLE` and `ALTER TABLE` statements that would result in tables violating these restrictions are not allowed.

**ALTER TABLE ... ORDER BY.** An `ALTER TABLE ... ORDER BY column` statement run against a partitioned table causes ordering of rows only within each partition.

**Effects on REPLACE statements by modification of primary keys.** It can be desirable in some cases (see [Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#)) to modify a table's primary key. Be aware that, if your application uses `REPLACE` statements and you do this, the results of these statements can be drastically altered. See [Section 13.2.8, “REPLACE Statement”](#), for more information and an example.

**FULLTEXT indexes.**

Partitioned tables do not support FULLTEXT indexes or searches, even for partitioned tables employing the InnoDB or MyISAM storage engine.

**Spatial columns.** Columns with spatial data types such as `POINT` or `GEOMETRY` cannot be used in partitioned tables.

**Temporary tables.**

Temporary tables cannot be partitioned. (Bug #17497)

**Log tables.** It is not possible to partition the log tables; an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error.

**Data type of partitioning key.**

A partitioning key must be either an integer column or an expression that resolves to an integer. Expressions employing `ENUM` columns cannot be used. The column or expression value may also be `NULL`. (See [Section 22.2.7, “How MySQL Partitioning Handles NULL”](#).)

There are two exceptions to this restriction:

1. When partitioning by `[LINEAR] KEY`, it is possible to use columns of any valid MySQL data type other than `TEXT` or `BLOB` as partitioning keys, because MySQL's internal key-hashing functions produce the correct data type from these types. For example, the following two `CREATE TABLE` statements are valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;

CREATE TABLE tke
(c1 ENUM('red', 'orange', 'yellow', 'green', 'blue', 'indigo', 'violet'))
PARTITION BY LINEAR KEY(c1)
PARTITIONS 6;
```

2. When partitioning by `RANGE COLUMNS` or `LIST COLUMNS`, it is possible to use string, `DATE`, and `DATETIME` columns. For example, each of the following `CREATE TABLE` statements is valid:

```
CREATE TABLE rc (c1 INT, c2 DATE)
PARTITION BY RANGE COLUMNS(c2) (
 PARTITION p0 VALUES LESS THAN('1990-01-01'),
 PARTITION p1 VALUES LESS THAN('1995-01-01'),
 PARTITION p2 VALUES LESS THAN('2000-01-01'),
 PARTITION p3 VALUES LESS THAN('2005-01-01'),
 PARTITION p4 VALUES LESS THAN(MAXVALUE)
);

CREATE TABLE lc (c1 INT, c2 CHAR(1))
PARTITION BY LIST COLUMNS(c2) (
 PARTITION p0 VALUES IN('a', 'd', 'g', 'j', 'm', 'p', 's', 'v', 'y'),
 PARTITION p1 VALUES IN('b', 'e', 'h', 'k', 'n', 'q', 't', 'w', 'z'),
 PARTITION p2 VALUES IN('c', 'f', 'i', 'l', 'o', 'r', 'u', 'x', NULL)
);
```

Neither of the preceding exceptions applies to `BLOB` or `TEXT` column types.

### Subqueries.

A partitioning key may not be a subquery, even if that subquery resolves to an integer value or `NULL`.

**Column index prefixes not supported for key partitioning.** When creating a table that is partitioned by key, any columns in the partitioning key which use column prefixes are not used in the table's partitioning function. Consider the following `CREATE TABLE` statement, which has three `VARCHAR` columns, and whose primary key uses all three columns and specifies prefixes for two of them:

```
CREATE TABLE t1 (
 a VARCHAR(10000),
 b VARCHAR(25),
 c VARCHAR(10),
 PRIMARY KEY (a(10), b, c(2))
) PARTITION BY KEY() PARTITIONS 2;
```

This statement is accepted, but the resulting table is actually created as if you had issued the following statement, using only the primary key column which does not include a prefix (column `b`) for the partitioning key:

```
CREATE TABLE t1 (
 a VARCHAR(10000),
 b VARCHAR(25),
 c VARCHAR(10),
 PRIMARY KEY (a(10), b, c(2))
) PARTITION BY KEY(b) PARTITIONS 2;
```

No warning is issued or any other indication provided that this has occurred, except in the event that all columns specified for the partitioning key use prefixes, in which case the statement fails with the error message shown here:

```
mysql> CREATE TABLE t2 (
-> a VARCHAR(10000),
-> b VARCHAR(25),
-> c VARCHAR(10),
-> PRIMARY KEY (a(10), b(5), c(2))
->) PARTITION BY KEY() PARTITIONS 2;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the
table's partitioning function
```

This also occurs when altering or upgrading such tables, and includes cases in which the columns used in the partitioning function are defined implicitly as those in the table's primary key by employing an empty `PARTITION BY KEY()` clause.

This is a known issue which is addressed in MySQL 8.0 by deprecating the permissive behavior; in MySQL 8.0, if any columns using prefixes are included in a table's partitioning function, the server logs

an appropriate warning for each such column, or raises a descriptive error if necessary. (Allowing the use of columns with prefixes in partitioning keys is subject to removal altogether in a future version of MySQL.)

For general information about partitioning tables by key, see [Section 22.2.5, “KEY Partitioning”](#).

### Issues with subpartitions.

Subpartitions must use `HASH` or `KEY` partitioning. Only `RANGE` and `LIST` partitions may be subpartitioned; `HASH` and `KEY` partitions cannot be subpartitioned.

`SUBPARTITION BY KEY` requires that the subpartitioning column or columns be specified explicitly, unlike the case with `PARTITION BY KEY`, where it can be omitted (in which case the table's primary key column is used by default). Consider the table created by this statement:

```
CREATE TABLE ts (
 id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 name VARCHAR(30)
);
```

You can create a table having the same columns, partitioned by `KEY`, using a statement such as this one:

```
CREATE TABLE ts (
 id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 name VARCHAR(30)
)
PARTITION BY KEY()
PARTITIONS 4;
```

The previous statement is treated as though it had been written like this, with the table's primary key column used as the partitioning column:

```
CREATE TABLE ts (
 id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 name VARCHAR(30)
)
PARTITION BY KEY(id)
PARTITIONS 4;
```

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```
mysql> CREATE TABLE ts (
-> id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
-> name VARCHAR(30)
->)
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY()
-> SUBPARTITIONS 4
-> (
-> PARTITION p0 VALUES LESS THAN (100),
-> PARTITION p1 VALUES LESS THAN (MAXVALUE)
->);
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near ')'

mysql> CREATE TABLE ts (
-> id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
-> name VARCHAR(30)
->)
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY(id)
-> SUBPARTITIONS 4
-> (
-> PARTITION p0 VALUES LESS THAN (100),
-> PARTITION p1 VALUES LESS THAN (MAXVALUE)
```

```
->);
Query OK, 0 rows affected (0.07 sec)
```

This is a known issue (see Bug #51470).

**DATA DIRECTORY and INDEX DIRECTORY options.** `DATA DIRECTORY` and `INDEX DIRECTORY` are subject to the following restrictions when used with partitioned tables:

- Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored (see Bug #32091).
- On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions of `MyISAM` tables. However, you can use `DATA DIRECTORY` for individual partitions or subpartitions of `InnoDB` tables.

**Repairing and rebuilding partitioned tables.** The statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE` are supported for partitioned tables.

In addition, you can use `ALTER TABLE ... REBUILD PARTITION` to rebuild one or more partitions of a partitioned table; `ALTER TABLE ... REORGANIZE PARTITION` also causes partitions to be rebuilt. See [Section 13.1.8, “ALTER TABLE Statement”](#), for more information about these two statements.

Starting in MySQL 5.7.2, `ANALYZE`, `CHECK`, `OPTIMIZE`, `REPAIR`, and `TRUNCATE` operations are supported with subpartitions. `REBUILD` was also accepted syntax prior to MySQL 5.7.5, although this had no effect. (Bug #19075411, Bug #73130) See also [Section 13.1.8.1, “ALTER TABLE Partition Operations”](#).

`mysqlcheck`, `myisamchk`, and `myisampack` are not supported with partitioned tables.

**FOR EXPORT option (FLUSH TABLES).** The `FLUSH TABLES` statement's `FOR EXPORT` option is not supported for partitioned `InnoDB` tables in MySQL 5.7.4 and earlier. (Bug #16943907)

**File name delimiters for partitions and subpartitions.** Table partition and subpartition file names include generated delimiters such as `#P#` and `#SP#`. The lettercase of such delimiters can vary and should not be depended upon.

## 22.6.1 Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression.* (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```
CREATE TABLE t1 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 UNIQUE KEY (col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 UNIQUE KEY (col1),
 UNIQUE KEY (col3)
```

```
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 UNIQUE KEY (col1, col2, col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 UNIQUE KEY (col1, col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

This example shows the error produced in such cases:

```
mysql> CREATE TABLE t3 (
-> col1 INT NOT NULL,
-> col2 DATE NOT NULL,
-> col3 INT NOT NULL,
-> col4 INT NOT NULL,
-> UNIQUE KEY (col1, col2),
-> UNIQUE KEY (col3)
->)
-> PARTITION BY HASH(col1 + col3)
-> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

```
mysql> CREATE TABLE t3 (
-> col1 INT NOT NULL,
-> col2 DATE NOT NULL,
-> col3 INT NOT NULL,
-> col4 INT NOT NULL,
-> UNIQUE KEY (col1, col2, col3),
-> UNIQUE KEY (col3)
->)
-> PARTITION BY HASH(col3)
-> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```
CREATE TABLE t4 (
 col1 INT NOT NULL,
 col2 INT NOT NULL,
```

```

 col3 INT NOT NULL,
 col4 INT NOT NULL,
 UNIQUE KEY (col1, col3),
 UNIQUE KEY (col2, col4)
);

```

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```

CREATE TABLE t5 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t6 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 PRIMARY KEY(col1, col3),
 UNIQUE KEY(col2)
)
PARTITION BY HASH(YEAR(col2))
PARTITIONS 4;

```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```

CREATE TABLE t7 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t8 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 PRIMARY KEY(col1, col2, col4),
 UNIQUE KEY(col2, col1)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider the partitioned table created as shown here:

```

mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
-> PARTITION BY RANGE(c1) (
-> PARTITION p0 VALUES LESS THAN (10),
-> PARTITION p1 VALUES LESS THAN (20),
-> PARTITION p2 VALUES LESS THAN (30),
-> PARTITION p3 VALUES LESS THAN (40)
->);
Query OK, 0 rows affected (0.12 sec)

```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```
possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0 Duplicates: 0 Warnings: 0

drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0 Duplicates: 0 Warnings: 0

use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0 Duplicates: 0 Warnings: 0

drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```
fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` created as shown here:

```
mysql> CREATE TABLE np_pk (
 -> id INT NOT NULL AUTO_INCREMENT,
 -> name VARCHAR(50),
 -> added DATE,
 -> PRIMARY KEY (id)
 ->);
Query OK, 0 rows affected (0.08 sec)
```

The following `ALTER TABLE` statement fails with an error, because the `added` column is not part of any unique key in the table:

```
mysql> ALTER TABLE np_pk
 -> PARTITION BY HASH(TO_DAYS(added))
 -> PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```
mysql> ALTER TABLE np_pk
 -> PARTITION BY HASH(id)
 -> PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

## 22.6.2 Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.

**MERGE storage engine.** User-defined partitioning and the `MERGE` storage engine are not compatible. Tables using the `MERGE` storage engine cannot be partitioned. Partitioned tables cannot be merged.

**FEDERATED storage engine.** Partitioning of `FEDERATED` tables is not supported; it is not possible to create partitioned `FEDERATED` tables.

**CSV storage engine.** Partitioned tables using the `CSV` storage engine are not supported; it is not possible to create partitioned `CSV` tables.

**InnoDB storage engine.** `InnoDB` foreign keys and MySQL partitioning are not compatible. Partitioned `InnoDB` tables cannot have foreign key references, nor can they have columns referenced by foreign keys. `InnoDB` tables which have or which are referenced by foreign keys cannot be partitioned.

`InnoDB` does not support the use of multiple disks for subpartitions. (This is currently supported only by `MyISAM`.)

In addition, `ALTER TABLE ... OPTIMIZE PARTITION` does not work correctly with partitioned tables that use the `InnoDB` storage engine. Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION`, instead, for such tables. For more information, see Section 13.1.8.1, “`ALTER TABLE` Partition Operations”.

**User-defined partitioning and the NDB storage engine (NDB Cluster).** Partitioning by `KEY` (including `LINEAR KEY`) is the only type of partitioning supported for the `NDB` storage engine. It is not possible under normal circumstances in NDB Cluster to create an NDB Cluster table using any partitioning type other than `[LINEAR] KEY`, and attempting to do so fails with an error.

*Exception (not for production):* It is possible to override this restriction by setting the `new` system variable on NDB Cluster SQL nodes to `ON`. If you choose to do this, you should be aware that tables using partitioning types other than `[LINEAR] KEY` are not supported in production. *In such cases, you can create and use tables with partitioning types other than `KEY` or `LINEAR KEY`, but you do this entirely at your own risk.*

The maximum number of partitions that can be defined for an `NDB` table depends on the number of data nodes and node groups in the cluster, the version of the NDB Cluster software in use, and other factors. See `NDB` and user-defined partitioning, for more information.

As of MySQL NDB Cluster 7.5.2, the maximum amount of fixed-size data that can be stored per partition in an `NDB` table is 128 TB. Previously, this was 16 GB.

`CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDB` table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

**Exception.** If a user-partitioned `NDB` table is created using an empty column-list (that is, using `PARTITION BY KEY()` or `PARTITION BY LINEAR KEY()`), then no explicit primary key is required.

**Upgrading partitioned tables.** When performing an upgrade, tables which are partitioned by `KEY` and which use any storage engine other than `NDB` must be dumped and reloaded.

**Same storage engine for all partitions.** All partitions of a partitioned table must use the same storage engine and it must be the same storage engine used by the table as a whole. In addition, if one does not specify an engine on the table level, then one must do either of the following when creating or altering a partitioned table:

- Do not specify any engine for *any* partition or subpartition
- Specify the engine for *all* partitions or subpartitions

## 22.6.3 Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Only the MySQL functions shown in the following list are allowed in partitioning expressions:

- `ABS()`
- `CEILING()` (see [CEILING\(\) and FLOOR\(\)](#))
- `DATEDIFF()`
- `DAY()`
- `DAYOFMONTH()`
- `DAYOFWEEK()`
- `DAYOFYEAR()`
- `EXTRACT()` (see [EXTRACT\(\) function with WEEK specifier](#))
- `FLOOR()` (see [CEILING\(\) and FLOOR\(\)](#))
- `HOUR()`
- `MICROSECOND()`
- `MINUTE()`
- `MOD()`
- `MONTH()`
- `QUARTER()`
- `SECOND()`
- `TIME_TO_SEC()`
- `TO_DAYS()`
- `TO_SECONDS()`
- `UNIX_TIMESTAMP()` (with `TIMESTAMP` columns)
- `WEEKDAY()`
- `YEAR()`
- `YEARWEEK()`

In MySQL 5.7, partition pruning is supported for the `TO_DAYS()`, `TO_SECONDS()`, `YEAR()`, and `UNIX_TIMESTAMP()` functions. See [Section 22.4, “Partition Pruning”](#), for more information.

**CEILING() and FLOOR().** Each of these functions returns an integer only if it is passed an argument of an exact numeric type, such as one of the `INT` types or `DECIMAL`. This means, for example, that the following `CREATE TABLE` statement fails with an error, as shown here:

```
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST(FLOOR(c))(
 -> PARTITION p0 VALUES IN (1,3,5),
 -> PARTITION p1 VALUES IN (2,4,6)
```

```
->);
ERROR 1490 (HY000): The PARTITION function returns the wrong type
```

**EXTRACT() function with WEEK specifier.** The value returned by the `EXTRACT()` function, when used as `EXTRACT(WEEK FROM col)`, depends on the value of the `default_week_format` system variable. For this reason, `EXTRACT()` is not permitted as a partitioning function when it specifies the unit as `WEEK`. (Bug #54483)

See [Section 12.6.2, “Mathematical Functions”](#), for more information about the return types of these functions, as well as [Section 11.1, “Numeric Data Types”](#).

## 22.6.4 Partitioning and Locking

For storage engines such as `MyISAM` that actually execute table-level locks when executing DML or DDL statements, such a statement in older versions of MySQL (5.6.5 and earlier) that affected a partitioned table imposed a lock on the table as a whole; that is, all partitions were locked until the statement was finished. In MySQL 5.7, *partition lock pruning* eliminates unneeded locks in many cases, and most statements reading from or updating a partitioned `MyISAM` table cause only the effected partitions to be locked. For example, a `SELECT` from a partitioned `MyISAM` table locks only those partitions actually containing rows that satisfy the `SELECT` statement's `WHERE` condition are locked.

For statements affecting partitioned tables using storage engines such as `InnoDB`, that employ row-level locking and do not actually perform (or need to perform) the locks prior to partition pruning, this is not an issue.

The next few paragraphs discuss the effects of partition lock pruning for various MySQL statements on tables using storage engines that employ table-level locks.

### Effects on DML statements

`SELECT` statements (including those containing unions or joins) lock only those partitions that actually need to be read. This also applies to `SELECT ... PARTITION`.

An `UPDATE` prunes locks only for tables on which no partitioning columns are updated.

`REPLACE` and `INSERT` lock only those partitions having rows to be inserted or replaced. However, if an `AUTO_INCREMENT` value is generated for any partitioning column then all partitions are locked.

`INSERT ... ON DUPLICATE KEY UPDATE` is pruned as long as no partitioning column is updated.

`INSERT ... SELECT` locks only those partitions in the source table that need to be read, although all partitions in the target table are locked.

Locks imposed by `LOAD DATA` statements on partitioned tables cannot be pruned.

The presence of `BEFORE INSERT` or `BEFORE UPDATE` triggers using any partitioning column of a partitioned table means that locks on `INSERT` and `UPDATE` statements updating this table cannot be pruned, since the trigger can alter its values: A `BEFORE INSERT` trigger on any of the table's partitioning columns means that locks set by `INSERT` or `REPLACE` cannot be pruned, since the `BEFORE INSERT` trigger may change a row's partitioning columns before the row is inserted, forcing the row into a different partition than it would be otherwise. A `BEFORE UPDATE` trigger on a partitioning column means that locks imposed by `UPDATE` or `INSERT ... ON DUPLICATE KEY UPDATE` cannot be pruned.

### Affected DDL statements

`CREATE VIEW` does not cause any locks.

`ALTER TABLE ... EXCHANGE PARTITION` prunes locks; only the exchanged table and the exchanged partition are locked.

`ALTER TABLE ... TRUNCATE PARTITION` prunes locks; only the partitions to be emptied are locked.

In addition, `ALTER TABLE` statements take metadata locks on the table level.

## Other statements

`LOCK TABLES` cannot prune partition locks.

`CALL stored_procedure(expr)` supports lock pruning, but evaluating `expr` does not.

`DO` and `SET` statements do not support partitioning lock pruning.

---

This chapter discusses stored database objects that are defined in terms of SQL code that is stored on the server for later execution.

Stored objects include these object types:

- Stored procedure: An object created with `CREATE PROCEDURE` and invoked using the `CALL` statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program.
- Stored function: An object created with `CREATE FUNCTION` and used much like a built-in function. You invoke it in an expression and it returns a value during expression evaluation.
- Trigger: An object created with `CREATE TRIGGER` that is associated with a table. A trigger is activated when a particular event occurs for the table, such as an insert or update.
- Event: An object created with `CREATE EVENT` and invoked by the server according to schedule.
- View: An object created with `CREATE VIEW` that when referenced produces a result set. A view acts as a virtual table.

Terminology used in this document reflects the stored object hierarchy:

- Stored routines include stored procedures and functions.
- Stored programs include stored routines, triggers, and events.
- Stored objects include stored programs and views.

This chapter describes how to use stored objects. The following sections provide additional information about SQL syntax for statements related to these objects, and about object processing:

- For each object type, there are `CREATE`, `ALTER`, and `DROP` statements that control which objects exist and how they are defined. See [Section 13.1, “Data Definition Statements”](#).
- The `CALL` statement is used to invoke stored procedures. See [Section 13.2.1, “CALL Statement”](#).
- Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See [Section 13.6, “Compound Statements”](#).
- Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see [Section 8.10.4, “Caching of Prepared Statements and Stored Programs”](#).

## 23.1 Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (`:`) characters. For example, the following stored procedure has a body made up of a `BEGIN ... END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
 SET @x = 0;
 REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END;
```

If you use the `mysql` client program to define a stored program containing semicolon characters, a problem arises. By default, `mysql` itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `:` before invoking the procedure. This enables the `:` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
-> SET @x = 0;
-> REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;
mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+-----+
| @x |
+-----+
| 1001 |
+-----+
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (`\`) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world! |
+-----+
1 row in set (0.00 sec)
```

## 23.2 Using Stored Routines

MySQL supports stored routines (procedures and functions). A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL installation procedure. If you are upgrading to MySQL 5.7 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.

## Additional Resources

- You may find the [Stored Procedures User Forum](#) of use when working with stored procedures and functions.
- For answers to some commonly asked questions regarding stored routines in MySQL, see [Section A.4, “MySQL 5.7 FAQ: Stored Procedures and Functions”](#).
- There are some restrictions on the use of stored routines. See [Section 23.8, “Restrictions on Stored Programs”](#).

- Binary logging for stored routines takes place as described in [Section 23.7, “Stored Program Binary Logging”](#).

### 23.2.1 Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see [Section 13.1.16, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#)). A procedure is invoked using a `CALL` statement (see [Section 13.2.1, “CALL Statement”](#)), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function’s name), and can return a scalar value. The body of a stored routine can use compound statements (see [Section 13.6, “Compound Statements”](#)).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see [Section 13.1.27, “DROP PROCEDURE and DROP FUNCTION Statements”](#)), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see [Section 13.1.6, “ALTER PROCEDURE Statement”](#)).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are not permitted.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See [Section 5.1.7, “Server System Variables”](#), for more information.

MySQL supports a very useful extension that enables the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See [mysql\\_real\\_connect\(\)](#), and [Multiple Statement Execution Support](#).

### 23.2.2 Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine is dropped). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.

- If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted to and dropped from the routine creator.
- The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. Manual manipulation of this table is not supported.

### 23.2.3 Stored Routine Metadata

To obtain metadata about stored routines:

- Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See [Section 24.3.21, “The INFORMATION\\_SCHEMA ROUTINES Table”](#).
- Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine definitions. See [Section 13.7.5.9, “SHOW CREATE PROCEDURE Statement”](#).
- Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine characteristics. See [Section 13.7.5.28, “SHOW PROCEDURE STATUS Statement”](#).
- Use the `SHOW PROCEDURE CODE` and `SHOW FUNCTION CODE` statements to see a representation of the internal implementation of the routine. See [Section 13.7.5.27, “SHOW PROCEDURE CODE Statement”](#).

### 23.2.4 Stored Procedures, Functions, Triggers, and LAST\_INSERT\_ID()

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see [Section 12.16, “Information Functions”](#)). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

## 23.3 Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when a statement inserts, updates, or deletes rows in the associated table. These row operations are trigger events. For example, rows can be inserted by `INSERT` or `LOAD DATA` statements, and an insert trigger activates for each inserted row. A trigger can be set to activate either before or after the trigger event. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

#### Important

MySQL triggers activate only for changes made to tables by SQL statements. This includes changes to base tables that underlie updatable views. Triggers do not activate for changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that triggers are not activated by updates made using the `NDB` API.

Triggers are not activated by changes in `INFORMATION_SCHEMA` or `performance_schema` tables. Those tables are actually views and triggers are not permitted on views.

The following sections describe the syntax for creating and dropping triggers, show some examples of how to use them, and indicate how to obtain trigger metadata.

## Additional Resources

- You may find the [Triggers User Forum](#) of use when working with triggers.
- For answers to commonly asked questions regarding triggers in MySQL, see [Section A.5, “MySQL 5.7 FAQ: Triggers”](#).
- There are some restrictions on the use of triggers; see [Section 23.8, “Restrictions on Stored Programs”](#).
- Binary logging for triggers takes place as described in [Section 23.7, “Stored Program Binary Logging”](#).

### 23.3.1 Trigger Syntax and Examples

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement, described in [Section 13.1.20, “CREATE TRIGGER Statement”](#), and [Section 13.1.31, “DROP TRIGGER Statement”](#).

Here is a simple example that associates a trigger with a table, to activate for `INSERT` operations. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
 FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.01 sec)
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger action time, the triggering event, and what to do when the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger activates before each row inserted into the table. The other permitted keyword here is `AFTER`.
- The keyword `INSERT` indicates the trigger event; that is, the type of operation that activates the trigger. In the example, `INSERT` operations cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` operations.
- The statement following `FOR EACH ROW` defines the trigger body; that is, the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering event. In the example, the trigger body is a simple `SET` that accumulates into a user variable the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----+
| Total amount inserted |
+-----+
| 1852.48 |
```

```
+-----+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

If you drop a table, any triggers for the table are also dropped.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

As of MySQL 5.7.2, it is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two `BEFORE UPDATE` triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a clause after `FOR EACH ROW` that indicates `FOLLOWS` or `PRECEDES` and the name of an existing trigger that also has the same trigger event and action time. With `FOLLOWS`, the new trigger activates after the existing trigger. With `PRECEDES`, the new trigger activates before the existing trigger.

For example, the following trigger definition defines another `BEFORE INSERT` trigger for the `account` table:

```
mysql> CREATE TRIGGER ins_transaction BEFORE INSERT ON account
 FOR EACH ROW PRECEDES ins_sum
 SET
 @deposits = @deposits + IF(NEW.amount > 0, NEW.amount, 0),
 @withdrawals = @withdrawals + IF(NEW.amount < 0, -NEW.amount, 0);
Query OK, 0 rows affected (0.01 sec)
```

This trigger, `ins_transaction`, is similar to `ins_sum` but accumulates deposits and withdrawals separately. It has a `PRECEDES` clause that causes it to activate before `ins_sum`; without that clause, it would activate after `ins_sum` because it is created after `ins_sum`.

Before MySQL 5.7.2, there cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. To work around this, you can define a trigger that executes multiple statements by using the `BEGIN ... END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

Within the trigger body, the `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. `OLD` and `NEW` are MySQL extensions to triggers; they are not case-sensitive.

In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. You can refer to a column named with `NEW` if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or used to update a row. (Such a `SET` statement has no effect in an `AFTER` trigger because the row change has already occurred.)

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the sequence number that is generated automatically when the new row actually is inserted.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is permitted within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a

trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `:` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value must be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
FOR EACH ROW
BEGIN
 IF NEW.amount < 0 THEN
 SET NEW.amount = 0;
 ELSEIF NEW.amount > 100 THEN
 SET NEW.amount = 100;
 END IF;
END;;
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to execute the same code from within several triggers.

There are limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction, such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`. (`ROLLBACK` to `SAVEPOINT` is permitted because it does not end a transaction.).

See also [Section 23.8, “Restrictions on Stored Programs”](#).

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.
- A `BEFORE` trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.
- An `AFTER` trigger is executed only if any `BEFORE` triggers and the row operation execute successfully.
- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

Triggers can contain direct references to tables by name, such as the trigger named `testref` shown in this example:

```
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
 a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 b4 INT DEFAULT 0
);
delimiter |
```

```

CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW
BEGIN
 INSERT INTO test2 SET a2 = NEW.a1;
 DELETE FROM test3 WHERE a3 = NEW.a1;
 UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;
|
delimiter ;
INSERT INTO test3 (a3) VALUES
 (NULL), (NULL), (NULL), (NULL), (NULL),
 (NULL), (NULL), (NULL), (NULL);
INSERT INTO test4 (a4) VALUES
 (0), (0), (0), (0), (0), (0), (0), (0), (0);

```

Suppose that you insert the following values into table `test1` as shown here:

```

mysql> INSERT INTO test1 VALUES
 (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8 Duplicates: 0 Warnings: 0

```

As a result, the four tables contain the following data:

```

mysql> SELECT * FROM test1;
+-----+
| a1 |
+-----+
| 1 |
| 3 |
| 1 |
| 7 |
| 1 |
| 8 |
| 4 |
| 4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test2;
+-----+
| a2 |
+-----+
| 1 |
| 3 |
| 1 |
| 7 |
| 1 |
| 8 |
| 4 |
| 4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test3;
+-----+
| a3 |
+-----+
| 2 |
| 5 |
| 6 |
| 9 |
| 10 |
+-----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM test4;
+-----+-----+
| a4 | b4 |
+-----+-----+

```

```
+---+---+
| 1 | 3 |
| 2 | 0 |
| 3 | 1 |
| 4 | 2 |
| 5 | 0 |
| 6 | 0 |
| 7 | 1 |
| 8 | 1 |
| 9 | 0 |
| 10 | 0 |
+---+---+
10 rows in set (0.00 sec)
```

### 23.3.2 Trigger Metadata

To obtain metadata about triggers:

- Query the `TRIGGERS` table of the `INFORMATION_SCHEMA` database. See [Section 24.3.29, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).
- Use the `SHOW CREATE TRIGGER` statement. See [Section 13.7.5.11, “SHOW CREATE TRIGGER Statement”](#).
- Use the `SHOW TRIGGERS` statement. See [Section 13.7.5.38, “SHOW TRIGGERS Statement”](#).

## 23.4 Using the Event Scheduler

The *MySQL Event Scheduler* manages the scheduling and execution of events, that is, tasks that run according to a schedule. The following discussion covers the Event Scheduler and is divided into the following sections:

- [Section 23.4.1, “Event Scheduler Overview”](#), provides an introduction to and conceptual overview of MySQL Events.
- [Section 23.4.3, “Event Syntax”](#), discusses the SQL statements for creating, altering, and dropping MySQL Events.
- [Section 23.4.4, “Event Metadata”](#), shows how to obtain information about events and how this information is stored by the MySQL Server.
- [Section 23.4.6, “The Event Scheduler and MySQL Privileges”](#), discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.

Stored routines require the `event` table in the `mysql` database. This table is created during the MySQL 5.7 installation procedure. If you are upgrading to MySQL 5.7 from an earlier version, be sure to update your grant tables to make sure that the `event` table exists. See [Section 2.11, “Upgrading MySQL”](#).

## Additional Resources

- You may find the [MySQL Event Scheduler User Forum](#) of use when working with scheduled events.
- There are some restrictions on the use of events; see [Section 23.8, “Restrictions on Stored Programs”](#).
- Binary logging for events takes place as described in [Section 23.7, “Stored Program Binary Logging”](#).

### 23.4.1 Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as *scheduled events*. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at

a specific date and time. Conceptually, this is similar to the idea of the Unix `crontab` (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term *events* to avoid confusion with triggers of the type discussed in [Section 23.3, “Using Triggers”](#). Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL, an event is uniquely identified by its name and the schema to which it is assigned.
- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a `BEGIN ... END` block if desired (see [Section 13.6, “Compound Statements”](#)). An event’s timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event’s schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. *A user may include statements in an event’s action which require privileges that the user does not actually have.* The event creation or modification statement succeeds but the event’s action fails. See [Section 23.4.6, “The Event Scheduler and MySQL Privileges”](#) for details.
- Many of the properties of an event can be set or modified using SQL statements. These properties include the event’s name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See [Section 13.1.2, “ALTER EVENT Statement”](#).

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement affecting that event. An event can be modified by any user having the `EVENT` privilege on the database for which the event is defined. See [Section 23.4.6, “The Event Scheduler and MySQL Privileges”](#).

- An event’s action statement may include most SQL statements permitted within stored routines. For restrictions, see [Section 23.8, “Restrictions on Stored Programs”](#).

## 23.4.2 Event Scheduler Configuration

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `PROCESS` privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global `event_scheduler` system variable determines whether the Event Scheduler is enabled and running on the server. It has one of these 3 values, which affect event scheduling as described here:

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed. `OFF` is the default value for `event_scheduler`.

When the Event Scheduler is stopped (`event_scheduler` is `OFF`), it can be started by setting the value of `event_scheduler` to `ON`. (See next item.)

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

When the Event Scheduler is `ON`, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
 Id: 1
 User: root
 Host: localhost
 db: NULL
Command: Query
 Time: 0
 State: NULL
 Info: show processlist
***** 2. row *****
 Id: 2
 User: event_scheduler
 Host: localhost
 db: NULL
Command: Daemon
 Time: 3
 State: Waiting for next activation
 Info: NULL
2 rows in set (0.00 sec)
```

Event scheduling can be stopped by setting the value of `event_scheduler` to `OFF`.

- **DISABLED**: This value renders the Event Scheduler nonoperational. When the Event Scheduler is `DISABLED`, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

If the Event Scheduler status has not been set to `DISABLED`, `event_scheduler` can be toggled between `ON` and `OFF` (using `SET`). It is also possible to use `0` for `OFF`, and `1` for `ON` when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```
SET GLOBAL event_scheduler = ON;
SET @@GLOBAL.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@GLOBAL.event_scheduler = 1;
```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```
SET GLOBAL event_scheduler = OFF;
SET @@GLOBAL.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@GLOBAL.event_scheduler = 0;
```

Although `ON` and `OFF` have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of `OFF`, `ON`, or `DISABLED`. `DISABLED` has no numeric equivalent. For this reason, `ON` and `OFF` are usually preferred over `1` and `0` when setting this variable.

Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:

```
mysql> SET @event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL
```

```
variable and should be set with SET GLOBAL
```

### Important

It is possible to set the Event Scheduler to `DISABLED` only at server startup. If `event_scheduler` is `ON` or `OFF`, you cannot set it to `DISABLED` at runtime. Also, if the Event Scheduler is set to `DISABLED` at startup, you cannot change the value of `event_scheduler` at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

```
--event-scheduler=DISABLED
```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it can be read by the server (for example, in a `[mysqld]` section):

```
event_scheduler=DISABLED
```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command-line option, or after removing or commenting out the line containing `event-scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

### Note

You can issue event-manipulation statements when `event_scheduler` is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

Starting the MySQL server with the `--skip-grant-tables` option causes `event_scheduler` to be set to `DISABLED`, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file (Bug #26807).

For SQL statements used to create, alter, and drop events, see [Section 23.4.3, “Event Syntax”](#).

MySQL provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See [Section 23.4.4, “Event Metadata”](#), and [Section 24.3.8, “The INFORMATION\\_SCHEMA EVENTS Table”](#), for more information.

For information regarding event scheduling and the MySQL privilege system, see [Section 23.4.6, “The Event Scheduler and MySQL Privileges”](#).

## 23.4.3 Event Syntax

MySQL provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See [Section 13.1.12, “CREATE EVENT Statement”](#).
- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See [Section 13.1.2, “ALTER EVENT Statement”](#).
- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See [Section 13.1.23, “DROP EVENT Statement”](#). Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See [Section 13.1.12, “CREATE EVENT Statement”](#).

An event can be dropped by any user having the `EVENT` privilege for the database on which the event is defined. See [Section 23.4.6, “The Event Scheduler and MySQL Privileges”](#).

## 23.4.4 Event Metadata

To obtain metadata about events:

- Query the `event` table of the `mysql` database.
- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See [Section 24.3.8, “The INFORMATION\\_SCHEMA EVENTS Table”](#).
- Use the `SHOW CREATE EVENT` statement. See [Section 13.7.5.7, “SHOW CREATE EVENT Statement”](#).
- Use the `SHOW EVENTS` statement. See [Section 13.7.5.18, “SHOW EVENTS Statement”](#).

### Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session `time_zone` value that is initialized from the server's global `time_zone` value when the session begins but may be changed during the session.

The session time zone that is current when a `CREATE EVENT` or `ALTER EVENT` statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the `mysql.event` table, the `execute_at`, `starts`, and `ends` times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The `last_executed` time is also stored in UTC.

If you select information from `mysql.event`, the times just mentioned are retrieved as UTC values. These times can also be obtained by selecting from the `INFORMATION_SCHEMA.EVENTS` table or from `SHOW EVENTS`, but they are reported as ETZ values. Other times available from these sources indicate when an event was created or last altered; these are displayed as STZ values. The following table summarizes representation of event times.

| Value         | <code>mysql.event</code> | <code>INFORMATION_SCHEMA.EVENTS</code> |     |
|---------------|--------------------------|----------------------------------------|-----|
| Execute at    | UTC                      | ETZ                                    | ETZ |
| Starts        | UTC                      | ETZ                                    | ETZ |
| Ends          | UTC                      | ETZ                                    | ETZ |
| Last executed | UTC                      | ETZ                                    | n/a |
| Created       | STZ                      | STZ                                    | n/a |
| Last altered  | STZ                      | STZ                                    | n/a |

## 23.4.5 Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's error log. See [Section 23.4.6, “The Event Scheduler and MySQL Privileges”](#) for an example.

To obtain information about the state of the Event Scheduler for debugging and troubleshooting purposes, run `mysqladmin debug` (see [Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”](#)); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:

```

Events status:
LLA = Last Locked At LUA = Last Unlocked At
WOC = Waiting On Condition DL = Data Locked

Event scheduler status:
State : INITIALIZED
Thread id : 0
LLA : n/a:0
LUA : n/a:0
WOC : NO
Workers : 0
Executed : 0
Data locked: NO

Event queue status:
Element count : 0
Data locked : NO
Attempting lock : NO
LLA : init_queue:95
LUA : init_queue:103
WOC : NO
Next activation : never

```

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For example, for `SELECT ... INTO var_list` statements, if the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). For either condition, you can avoid having the warnings be logged by declaring a condition handler; see [Section 13.6.7.2, “DECLARE ... HANDLER Statement”](#). For statements that may retrieve multiple rows, another strategy is to use `LIMIT 1` to limit the result set to a single row.

### 23.4.6 The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` system variable. This requires privileges sufficient to set global system variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

The `EVENT` privilege governs the creation, modification, and deletion of events. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please
consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
```

```
ON SCHEDULE
EVERY 10 SECOND
DO
 INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (`hostname.err`), you can see that the event is executing, but the action it is attempting to perform fails:

```
2013-09-24T12:41:31.261992Z 25 [ERROR] Event Scheduler:
[jon@ghidora][cookbook.e_store_ts] INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
2013-09-24T12:41:31.262022Z 25 [Note] Event Scheduler:
[jon@ghidora].[myschema.e_store_ts] event execution failed.
2013-09-24T12:41:41.271796Z 26 [ERROR] Event Scheduler:
[jon@ghidora][cookbook.e_store_ts] INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
2013-09-24T12:41:41.272761Z 26 [Note] Event Scheduler:
[jon@ghidora].[myschema.e_store_ts] event execution failed.
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME='e_store_ts'
> AND EVENT_SCHEMA='myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00
ENDS: 0000-00-00 00:00:00
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2006-02-09 22:36:06
LAST_ALTERED: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT:
1 row in set (0.00 sec)
```

To rescind the `EVENT` privilege, use the `REVOKE` statement. In this example, the `EVENT` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

### Important

Revoking the `EVENT` privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user `jon@ghidora` has been granted the `EVENT` and `INSERT` privileges on the `myschema` schema. This user then creates the following event:

```
CREATE EVENT e_insert
 ON SCHEDULE
 EVERY 7 SECOND
 DO
 INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT` privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- `DROP USER jon@ghidora;`
- `RENAME USER jon@ghidora TO someotherguy@ghidora;`

You can verify that this is true by examining the `mysql.event` table (discussed later in this section) or the `INFORMATION_SCHEMA.EVENTS` table (see [Section 24.3.8, “The INFORMATION\\_SCHEMA EVENTS Table”](#)) before and after issuing a `DROP USER` or `RENAME USER` statement.

Event definitions are stored in the `mysql.event` table. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```
DELETE FROM mysql.event
 WHERE db = 'myschema'
 AND name = 'e_insert';
```

It is very important to match the event name and database schema name when deleting rows from the `mysql.event` table. This is because different events of the same name can exist in different schemas.

Users' `EVENT` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values '`Y`' or '`N`'. '`N`' is the default. `mysql.user.Event_priv` is set to '`Y`' for a given user only if that user has the global `EVENT` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to '`Y`'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

Five status variables provide counts of event-related operations (but *not* of statements executed by events; see [Section 23.8, “Restrictions on Stored Programs”](#)). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.

## 23.5 Using Views

MySQL supports views, including updatable views. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

### Additional Resources

- You may find the [Views User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see [Section A.6, “MySQL 5.7 FAQ: Views”](#).
- There are some restrictions on the use of views; see [Section 23.9, “Restrictions on Views”](#).

### 23.5.1 View Syntax

The `CREATE VIEW` statement creates a new view (see [Section 13.1.21, “CREATE VIEW Statement”](#)). To alter the definition of a view or drop a view, use `ALTER VIEW` (see [Section 13.1.10, “ALTER VIEW Statement”](#)), or `DROP VIEW` (see [Section 13.1.32, “DROP VIEW Statement”](#)).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+----+----+-----+
| qty | price | value |
+----+----+-----+
| 3 | 50 | 150 |
| 5 | 60 | 300 |
+----+----+-----+
mysql> SELECT * FROM v WHERE qty = 5;
+----+----+-----+
| qty | price | value |
+----+----+-----+
| 5 | 60 | 300 |
+----+----+-----+
```

### 23.5.2 View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`.

- For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.
- For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.
- For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

- If no `ALGORITHM` clause is present, the default algorithm is determined by the value of the `derived_merge` flag of the `optimizer_switch` system variable. For additional discussion, see [Section 8.2.2.4, “Optimizing Derived Tables and View References with Merging or Materialization”](#).

A reason to specify `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the `MERGE` algorithm cannot be used, a temporary table must be used instead. Constructs that prevent merging are the same as those that prevent merging in derived tables. Examples are `SELECT DISTINCT` or `LIMIT` in the subquery. For details, see [Section 8.2.2.4, “Optimizing Derived Tables and View References with Merging or Materialization”](#).

### 23.5.3 Updatable and Insertable Views

Some views are updatable and references to them can be used to specify tables to be updated in data change statements. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. Derived tables can also be specified in multiple-table `UPDATE` and `DELETE` statements, but can only be used for reading data to specify rows to be updated or deleted. Generally, the view references must be updatable, meaning that they may be merged and not materialized. Composite views have more complex rules.

For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Subquery in the select list

Before MySQL 5.7.11, subqueries in the select list fail for `INSERT`, but are okay for `UPDATE`, `DELETE`. As of MySQL 5.7.11, that is still true for nondependent subqueries. For dependent subqueries in the select list, no data change statements are permitted.

- Certain joins (see additional join discussion later in this section)
- Reference to nonupdatable view in the `FROM` clause
- Subquery in the `WHERE` clause that refers to a table in the `FROM` clause
- Refers only to literal values (in this case, there is no underlying table to update)
- `ALGORITHM = TEMPTABLE` (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table (fails for `INSERT`, okay for `UPDATE`, `DELETE`)

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see [Section 13.1.18.7, “CREATE TABLE and Generated Columns”](#).

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the `MERGE` algorithm. For this to work, the view must use an inner join (not an outer join or a `UNION`). Also, only a single table in the view definition can be updated, so the `SET` clause must name only columns from one of the tables in the view. Views that use `UNION ALL` are not permitted even though they might be theoretically updatable.

With respect to insertability (being updatable with `INSERT` statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references. They must not be expressions, such as these:

```
3.14159
col1 + 3
UPPER(col2)
```

```
col3 / col4
(subquery)
```

MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `INFORMATION_SCHEMA.VIEWS` table displays the status of this flag.

If a view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and are rejected. (Even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The `IS_UPDATABLE` flag may be unreliable if a view depends on one or more other views, and one of these underlying views is updated. Regardless of the `IS_UPDATABLE` value, the server keeps track of the updatability of a view and correctly rejects data change operations to views that are not updatable. If the `IS_UPDATABLE` value for a view has become inaccurate due to changes to underlying views, the value can be updated by deleting and re-creating the view.

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See [Section 5.1.7, “Server System Variables”](#).

For the following discussion, suppose that these tables and views exist:

```
CREATE TABLE t1 (x INTEGER);
CREATE TABLE t2 (c INTEGER);
CREATE VIEW vmat AS SELECT SUM(x) AS s FROM t1;
CREATE VIEW vup AS SELECT * FROM t2;
CREATE VIEW vjoin AS SELECT * FROM vmat JOIN vup ON vmat.s=vup.c;
```

`INSERT`, `UPDATE`, and `DELETE` statements are permitted as follows:

- `INSERT`: The insert table of an `INSERT` statement may be a view reference that is merged. If the view is a join view, all components of the view must be updatable (not materialized). For a multiple-table updatable view, `INSERT` can work if it inserts into a single table.

This statement is invalid because one component of the join view is nonupdatable:

```
INSERT INTO vjoin (c) VALUES (1);
```

This statement is valid; the view contains no materialized components:

```
INSERT INTO vup (c) VALUES (1);
```

- `UPDATE`: The table or tables to be updated in an `UPDATE` statement may be view references that are merged. If a view is a join view, at least one component of the view must be updatable (this differs from `INSERT`).

In a multiple-table `UPDATE` statement, the updated table references of the statement must be base tables or updatable view references. Nonupdated table references may be materialized views or derived tables.

This statement is valid; column `c` is from the updatable part of the join view:

```
UPDATE vjoin SET c=c+1;
```

This statement is invalid; column `x` is from the nonupdatable part:

```
UPDATE vjoin SET x=x+1;
```

This statement is valid; the updated table reference of the multiple-table `UPDATE` is an updatable view (`vup`):

```
UPDATE vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...
SET c=c+1;
```

This statement is invalid; it tries to update a materialized derived table:

```
UPDATE vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...
SET s=s+1;
```

- **DELETE**: The table or tables to be deleted from in a **DELETE** statement must be merged views. Join views are not allowed (this differs from **INSERT** and **UPDATE**).

This statement is invalid because the view is a join view:

```
DELETE vjoin WHERE ...;
```

This statement is valid because the view is a merged (updatable) view:

```
DELETE vup WHERE ...;
```

This statement is valid because it deletes from a merged (updatable) view:

```
DELETE vup FROM vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...;
```

Additional discussion and examples follow.

Earlier discussion in this section pointed out that a view is not insertable if not all columns are simple column references (for example, if it contains columns that are expressions or composite expressions). Although such a view is not insertable, it can be updatable if you update only columns that are not expressions. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is an expression. But it is updatable if the update does not try to update `col2`. This update is permissible:

```
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update an expression column:

```
UPDATE v SET col2 = 0;
```

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

### 23.5.4 The View WITH CHECK OPTION Clause

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts to rows for which the `WHERE` clause in the `select_statement` is not true. It also prevents updates to rows for which the `WHERE` clause is true but the update would cause it to be not true (in other words, it prevents visible rows from being updated to nonvisible rows).

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCDED` keywords determine the scope of check testing when the view is defined in terms of another view. When neither keyword is given, the default is `CASCDED`.

Before MySQL 5.7.6, `WITH CHECK OPTION` testing works like this:

- With `LOCAL`, the view `WHERE` clause is checked, but no underlying views are checked.
- With `CASCDED`, the view `WHERE` clause is checked, then checking recurses to underlying views, adds `WITH CASCDED CHECK OPTION` to them (for purposes of the check; their definitions remain unchanged), and applies the same rules.
- With no check option, the view `WHERE` clause is not checked, and no underlying views are checked.

As of MySQL 5.7.6, `WITH CHECK OPTION` testing is standard-compliant (with changed semantics from previously for `LOCAL` and no check clause):

- With `LOCAL`, the view `WHERE` clause is checked, then checking recurses to underlying views and applies the same rules.
- With `CASCDED`, the view `WHERE` clause is checked, then checking recurses to underlying views, adds `WITH CASCDED CHECK OPTION` to them (for purposes of the check; their definitions remain unchanged), and applies the same rules.
- With no check option, the view `WHERE` clause is not checked, then checking recurses to underlying views, and applies the same rules.

Consider the definitions for the following table and set of views:

```
CREATE TABLE t1 (a INT);
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
WITH CHECK OPTION;
CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
WITH LOCAL CHECK OPTION;
CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
WITH CASCDED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. Before MySQL 5.7.6, because `v2` has a `LOCAL` check option, inserts are tested only against the `v2` check. `v3` has a `CASCDED` check option, so inserts are tested not only against the `v3` check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

As of MySQL 5.7.6, the semantics for `LOCAL` differ from previously: Inserts for `v2` are checked against its `LOCAL` check option, then (unlike before 5.7.6), the check recurses to `v1` and the rules are applied again. The rules for `v1` cause a check failure. The check for `v3` fails as before:

```
mysql> INSERT INTO v2 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v2'
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

## 23.5.5 View Metadata

To obtain metadata about views:

- Query the `VIEWS` table of the `INFORMATION_SCHEMA` database. See [Section 24.3.31, “The INFORMATION\\_SCHEMA VIEWS Table”](#).
- Use the `SHOW CREATE VIEW` statement. See [Section 13.7.5.13, “SHOW CREATE VIEW Statement”](#).

## 23.6 Stored Object Access Control

Stored programs (procedures, functions, triggers, and events) and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. The privileges applicable to execution of a stored object are controlled by its `DEFINER` attribute and `SQL SECURITY` characteristic.

- [The DEFINER Attribute](#)
- [The SQL SECURITY Characteristic](#)
- [Examples](#)

- [Orphan Stored Objects](#)
- [Risk-Minimization Guidelines](#)

## The DEFINER Attribute

A stored object definition can include a `DEFINER` attribute that names a MySQL account. If a definition omits the `DEFINER` attribute, the default object definer is the user who creates it.

The following rules determine which accounts you can specify as the `DEFINER` attribute for a stored object:

- If you have the `SUPER` privilege, you can specify any account as the `DEFINER` attribute. If the account does not exist, a warning is generated.
- Otherwise, the only permitted account is your own, specified either literally or as `CURRENT_USER` or `CURRENT_USER()`. You cannot set the definer to any other account.

Creating a stored object with a nonexistent `DEFINER` account creates an orphan object, which may have negative consequences; see [Orphan Stored Objects](#).

## The SQL SECURITY Characteristic

For stored routines (procedures and functions) and views, the object definition can include an `SQL SECURITY` characteristic with a value of `DEFINER` or `INVOKER` to specify whether the object executes in definer or invoker context. If the definition omits the `SQL SECURITY` characteristic, the default is definer context.

Triggers and events have no `SQL SECURITY` characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored object that executes in definer security context executes with the privileges of the account named by its `DEFINER` attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, `EXECUTE` to call a stored procedure or `SELECT` to select from a view), but during object execution, the invoker's privileges are ignored and only the `DEFINER` account privileges matter. If the `DEFINER` account has few privileges, the object is correspondingly limited in the operations it can perform. If the `DEFINER` account is highly privileged (such as an administrative account), the object can perform powerful operations *no matter who invokes it*.
- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The `DEFINER` attribute has no effect on object execution.

## Examples

Consider the following stored procedure, which is declared with `SQL SECURITY DEFINER` to execute in definer security context:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
 UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the `EXECUTE` privilege for `p1` can invoke it with a `CALL` statement. However, when `p1` executes, it does so in definer security context and thus executes with the privileges of `'admin'@'localhost'`, the account named as its `DEFINER` attribute. This account must have the `EXECUTE` privilege for `p1` as well as the `UPDATE` privilege for the table `t1` referenced within the object body. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to `p1` except that its `SQL SECURITY` characteristic is `INVOKER`:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
 UPDATE t1 SET counter = counter + 1;
END;
```

Unlike `p1`, `p2` executes in invoker security context and thus with the privileges of the invoking user regardless of the `DEFINER` attribute value. `p2` fails if the invoker lacks the `EXECUTE` privilege for `p2` or the `UPDATE` privilege for the table `t1`.

## Orphan Stored Objects

An orphan stored object is one for which its `DEFINER` attribute names a nonexistent account:

- An orphan stored object can be created by specifying a nonexistent `DEFINER` account at object-creation time.
- An existing stored object can become orphaned through execution of a `DROP USER` statement that drops the object `DEFINER` account, or a `RENAME USER` statement that renames the object `DEFINER` account.

An orphan stored object may be problematic in these ways:

- Because the `DEFINER` account does not exist, the object may not work as expected if it executes in definer security context:
  - For a stored routine, an error occurs at routine execution time if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.
  - For a trigger, it is not a good idea for trigger activation to occur until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.
  - For an event, an error occurs at event execution time if the account does not exist.
  - For a view, an error occurs when the view is referenced if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.
- The object may present a security risk if the nonexistent `DEFINER` account is subsequently re-created for a purpose unrelated to the object. In this case, the account “adopts” the object and, with the appropriate privileges, is able to execute it even if that is not intended.

To obtain information about the accounts used as stored object definers in a MySQL installation, query the `INFORMATION_SCHEMA`.

This query identifies which `INFORMATION_SCHEMA` tables describe objects that have a `DEFINER` attribute:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME FROM INFORMATION_SCHEMA.COLUMNS
 WHERE COLUMN_NAME = 'DEFINER';
+-----+-----+
| TABLE_SCHEMA | TABLE_NAME |
+-----+-----+
| information_schema | EVENTS |
| information_schema | ROUTINES |
| information_schema | TRIGGERS |
| information_schema | VIEWS |
+-----+-----+
```

The result tells you which tables to query to discover which stored object `DEFINER` values exist and which objects have a particular `DEFINER` value:

- To identify which **DEFINER** values exist in each table, use these queries:

```
SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.EVENTS;
SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.ROUTINES;
SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.TRIGGERS;
SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.VIEWS;
```

The query results are significant for any account displayed as follows:

- If the account exists, dropping or renaming it causes stored objects to become orphaned. If you plan to drop or rename the account, consider first dropping its associated stored objects or redefining them to have a different definer.
- If the account does not exist, creating it causes it to adopt currently orphaned stored objects. If you plan to create the account, consider whether the orphaned objects should be associated with it. If not, redefine them to have a different definer.

To redefine an object with a different definer, you can use **ALTER EVENT** or **ALTER VIEW** to directly modify the **DEFINER** account of events and views. For stored procedures and functions and for triggers, you must drop the object and re-create it with a different **DEFINER** account

- To identify which objects have a given **DEFINER** account, use these queries, substituting the account of interest for *user\_name@host\_name*:

```
SELECT EVENT_SCHEMA, EVENT_NAME FROM INFORMATION_SCHEMA.EVENTS
WHERE DEFINER = 'user_name@host_name';
SELECT ROUTINE_SCHEMA, ROUTINE_NAME, ROUTINE_TYPE
FROM INFORMATION_SCHEMA.ROUTINES
WHERE DEFINER = 'user_name@host_name';
SELECT TRIGGER_SCHEMA, TRIGGER_NAME FROM INFORMATION_SCHEMA.TRIGGERS
WHERE DEFINER = 'user_name@host_name';
SELECT TABLE_SCHEMA, TABLE_NAME FROM INFORMATION_SCHEMA.VIEWS
WHERE DEFINER = 'user_name@host_name';
```

For the **ROUTINES** table, the query includes the **ROUTINE\_TYPE** column so that output rows distinguish whether the **DEFINER** is for a stored procedure or stored function.

If the account you are searching for does not exist, any objects displayed by those queries are orphan objects.

## Risk-Minimization Guidelines

To minimize the risk potential for stored object creation and use, follow these guidelines:

- Do not create orphan stored objects; that is, objects for which the **DEFINER** attribute names a nonexistent account. Do not cause stored objects to become orphaned by dropping or renaming an account named by the **DEFINER** attribute of any existing object.
- For a stored routine or view, use **SQL SECURITY INVOKER** in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.
- If you create definer-context stored objects while using an account that has the **SUPER** privilege, specify an explicit **DEFINER** attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged **DEFINER** account only when absolutely necessary.
- Administrators can prevent users from creating stored objects that specify highly privileged **DEFINER** accounts by not granting them the **SUPER** privilege.
- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent references to these objects by not granting unauthorized users particular privileges:

- A stored routine cannot be referenced by a user who does not have the `EXECUTE` privilege for it.
- A view cannot be referenced by a user who does not have the appropriate privilege for it (`SELECT` to select from it, `INSERT` to insert into it, and so forth).

However, no such control exists for triggers and events because they always execute in definer context. The server invokes these objects automatically as necessary, and users do not reference them directly:

- A trigger is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges.
- An event is executed by the server on a scheduled basis.

In both cases, if the `DEFINER` account is highly privileged, the object may be able to perform sensitive or dangerous operations. This remains true if the privileges needed to create the object are revoked from the account of the user who created it. Administrators should be especially careful about granting users object-creation privileges.

## 23.7 Stored Program Binary Logging

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. (Binary log events differ from scheduled event stored objects.) The binary log has two important purposes:

- For replication, the binary log is used on source replication servers as a record of the statements to be sent to replica servers. The source sends the events contained in its binary log to its replicas, which execute those events to make the same data changes that were made on the source. See [Section 16.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 7.3.2, “Using Backups for Recovery”](#).

However, if logging occurs at the statement level, there are certain binary logging issues with respect to stored programs (stored procedures and functions, triggers, and events):

- In some cases, a statement might affect different sets of rows on source and replica.
- Replicated statements executed on a replica are processed by the replica SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on source and replica servers, so a user can write a routine containing a dangerous statement that executes only on the replica where it is processed by a thread that has full privileges.
- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on source and replica, or cause restored data to differ from the original data.

This section describes how MySQL handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid logging problems. It also provides additional information about the reasons for these conditions.

Unless noted otherwise, the remarks here assume that binary logging is enabled on the server (see [Section 5.4.4, “The Binary Log”](#).) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery. In MySQL 5.7, binary logging is not enabled by default, and you enable it using the `--log-bin` option.

In general, the issues described here result when binary logging occurs at the SQL statement level (statement-based binary logging). If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row

changes are logged, not the statements that make the changes. For stored procedures, this means that the `CALL` statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the replica side, only the row changes are seen, not the stored program invocation.

Mixed format binary logging (`binlog_format=MIXED`) uses statement-based binary logging, except for cases where only row-based binary logging is guaranteed to lead to proper results. With mixed format, when a stored function, stored procedure, trigger, event, or prepared statement contains anything that is not safe for statement-based binary logging, the entire statement is marked as unsafe and logged in row format. The statements used to create and drop procedures, functions, triggers, and events are always safe, and are logged in statement format. For more information about row-based, mixed, and statement-based logging, and how safe and unsafe statements are determined, see [Section 16.2.1, “Replication Formats”](#).

The conditions on the use of stored functions in MySQL can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required. (Depending on the `DEFINER` value in the function definition, `SUPER` might be required regardless of whether binary logging is enabled. See [Section 13.1.16, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#).)
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
 RETURN i;
END;
```

This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
 RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
 UPDATE t SET modtime = NOW() WHERE id = p_id;
 RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator. MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- When you attempt to execute a stored function, if `binlog_format=STATEMENT` is set, the `DETERMINISTIC` keyword must be specified in the function definition. If this is not the case, an error is generated and the function does not run, unless `log_bin_trust_function_creators=1` is specified to override this check (see below). For recursive function calls, the `DETERMINISTIC` keyword is required on the outermost call only. If row-based or mixed binary logging is in use, the statement is accepted and replicated even if the function was defined without the `DETERMINISTIC` keyword.
- Because MySQL does not check if a function really is deterministic at creation time, the invocation of a stored function with the `DETERMINISTIC` keyword might carry out an action that is unsafe for statement-based logging, or invoke a function or procedure containing unsafe statements. If this occurs when `binlog_format=STATEMENT` is set, a warning message is issued. If row-based or mixed binary logging is in use, no warning is issued, and the statement is replicated in row-based format.
- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable at server startup.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see [Section 16.4.1, “Replication Features and Issues”](#).

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might be invalid in some cases. For example, the `UUID()` function is nondeterministic (and does not replicate). Be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the replica side, the replica uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE EVENT`, `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP EVENT`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.
- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the source server:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
```

```
IF (a < 3) THEN
 INSERT INTO t2 VALUES (a);
END IF;
RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;
```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the replica, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
  - It is possible for a function to follow different execution paths on source and replica servers.
  - Statements executed on a replica are processed by the replica SQL thread which has full privileges.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a function, the user can write a function containing a dangerous statement that executes only on the replica where it is processed by a thread that has full privileges. For example, if the source and replica servers have server ID values of 1 and 2, respectively, a user on the source server could create and invoke an unsafe function `unsafe_func()` as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
 -> BEGIN
 -> IF @@server_id=2 THEN dangerous_statement; END IF;
 -> RETURN 1;
 -> END;
 -> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the replica executes them. Because the replica SQL thread has full privileges, it executes the dangerous statement. Thus, the function invocation has different effects on the source and replica and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error occurs:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable at server startup. If binary logging is not enabled, `log_bin_trust_function_creators`

does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:
  - It makes a replica different from the source.
  - Restored data is different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a source server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.
- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the source server are observed on replicas. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

`var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of `var_value`, and a “name” of `var_name`. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
| 14 |
+-----+
```

`NAME_CONST()` enables a logged standalone statement to be executed on a replica with the same effect as the original statement that was executed on the source within a stored procedure.

The use of `NAME_CONST()` can result in a problem for `CREATE TABLE ... SELECT` statements when the source column expressions refer to local variables. Converting these references to `NAME_CONST()` expressions can result in column names that are different on the source and replica servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when `myvar` has a value of 1:

```
CREATE TABLE t1 SELECT myvar;
```

That is rewritten as follows:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```

To ensure that the source and replica tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the replica with the same value as on the source. For example, if a statement refers to a variable `@my_var`, that statement is preceded in the binary log by the following statement, where `value` is the value of `@my_var` on the source:

```
SET @my_var = value;
```

- Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:
  - Updates to transactional tables are not logged.
  - Updates to nontransactional tables are logged because rollback does not cancel them.
  - Updates to a mix of transactional and nontransactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that replicas make the same changes and rollbacks as on the source.
- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

## 23.8 Restrictions on Stored Programs

- [SQL Statements Not Permitted in Stored Routines](#)
- [Restrictions for Stored Functions](#)

- Restrictions for Triggers
- Name Conflicts within Stored Routines
- Replication Considerations
- Debugging Considerations
- Unsupported Syntax from the SQL:2003 Standard
- Stored Routine Concurrency Considerations
- Event Scheduler Restrictions
- Stored Programs in NDB Cluster

These restrictions apply to the features described in [Chapter 23, \*Stored Objects\*](#).

Some of the restrictions noted here apply to all stored routines; that is, both to stored procedures and stored functions. There are also some [restrictions specific to stored functions](#) but not to stored procedures.

The restrictions for stored functions also apply to triggers. There are also some [restrictions specific to triggers](#).

The restrictions for stored procedures also apply to the `DO` clause of Event Scheduler event definitions. There are also some [restrictions specific to events](#).

## SQL Statements Not Permitted in Stored Routines

Stored routines cannot contain arbitrary SQL statements. The following statements are not permitted:

- The locking statements `LOCK TABLES` and `UNLOCK TABLES`.
- `ALTER VIEW`.
- `LOAD DATA`.
- SQL prepared statements (`PREPARE`, `EXECUTE`, `DEALLOCATE PREPARE`) can be used in stored procedures, but not stored functions or triggers. Thus, stored functions and triggers cannot use dynamic SQL (where you construct statements as strings and then execute them).
- Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. For a list of statements supported as prepared statements, see [Section 13.5, “Prepared Statements”](#). Exceptions are `SIGNAL`, `RESIGNAL`, and `GET DIAGNOSTICS`, which are not permissible as prepared statements but are permitted in stored programs.
- Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See [Section 13.5.1, “PREPARE Statement”](#).
- Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.

## Restrictions for Stored Functions

The following additional statements or operations are not permitted within stored functions. They are permitted within stored procedures, except stored procedures that are invoked from within a stored

function or trigger. For example, if you use `FLUSH` in a stored procedure, that stored procedure cannot be called from a stored function or trigger.

- Statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.
- Statements that return a result set. This includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. A function can process a result set either with `SELECT ... INTO var_list` or by using a cursor and `FETCH` statements. See [Section 13.2.9.1, “SELECT ... INTO Statement”](#), and [Section 13.6.6, “Cursors”](#).
- `FLUSH` statements.
- Stored functions cannot be used recursively.
- A stored function or trigger cannot modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.
- If you refer to a temporary table multiple times in a stored function under different aliases, a `Can't reopen table: 'tbl_name'` error occurs, even if the references occur in different statements within the function.
- `HANDLER ... READ` statements that invoke stored functions can cause replication errors and are disallowed.

## Restrictions for Triggers

For triggers, the following additional restrictions apply:

- Triggers are not activated by foreign key actions.
- When using row-based replication, triggers on the replica are not activated by statements originating on the source. The triggers on the replica are activated when using statement-based replication. For more information, see [Section 16.4.1.34, “Replication and Triggers”](#).
- The `RETURN` statement is not permitted in triggers, which cannot return a value. To exit a trigger immediately, use the `LEAVE` statement.
- Triggers are not permitted on tables in the `mysql` database. Nor are they permitted on `INFORMATION_SCHEMA` or `performance_schema` tables. Those tables are actually views and triggers are not permitted on views.
- The trigger cache does not detect when metadata of the underlying objects has changed. If a trigger uses a table and the table has changed since the trigger was loaded into the cache, the trigger operates using the outdated metadata.

## Name Conflicts within Stored Routines

The same identifier might be used for a routine parameter, a local variable, and a table column. Also, the same local variable name can be used in nested blocks. For example:

```
CREATE PROCEDURE p (i INT)
BEGIN
 DECLARE i INT DEFAULT 0;
 SELECT i FROM t;
 BEGIN
 DECLARE i INT DEFAULT 1;
 SELECT i FROM t;
 END;
END;
```

In such cases, the identifier is ambiguous and the following precedence rules apply:

- A local variable takes precedence over a routine parameter or table column.
- A routine parameter takes precedence over a table column.
- A local variable in an inner block takes precedence over a local variable in an outer block.

The behavior that variables take precedence over table columns is nonstandard.

## Replication Considerations

Use of stored routines can cause replication problems. This issue is discussed further in [Section 23.7, “Stored Program Binary Logging”](#).

The `--replicate-wild-do-table=db_name.tbl_name` option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*--db` options.

## Debugging Considerations

There are no stored routine debugging facilities.

## Unsupported Syntax from the SQL:2003 Standard

The MySQL stored routine syntax is based on the SQL:2003 standard. The following items from that standard are not currently supported:

- `UNDO` handlers
- `FOR` loops

## Stored Routine Concurrency Considerations

To prevent problems of interaction between sessions, when a client issues a statement, the server uses a snapshot of routines and triggers available for execution of the statement. That is, the server calculates a list of procedures, functions, and triggers that may be used during execution of the statement, loads them, and then proceeds to execute the statement. While the statement executes, it does not see changes to routines performed by other sessions.

For maximum concurrency, stored functions should minimize their side-effects; in particular, updating a table within a stored function can reduce concurrent operations on that table. A stored function acquires table locks before executing, to avoid inconsistency in the binary log due to mismatch of the order in which statements execute and when they appear in the log. When statement-based binary logging is used, statements that invoke a function are recorded rather than the statements executed within the function. Consequently, stored functions that update the same underlying tables do not execute in parallel. In contrast, stored procedures do not acquire table-level locks. All statements executed within stored procedures are written to the binary log, even for statement-based binary logging. See [Section 23.7, “Stored Program Binary Logging”](#).

## Event Scheduler Restrictions

The following limitations are specific to the Event Scheduler:

- Event names are handled in case-insensitive fashion. For example, you cannot have two events in the same database with the names `anEvent` and `AnEvent`.
- An event may not be created, altered, or dropped from within a stored program, if the event name is specified by means of a variable. An event also may not create, alter, or drop stored routines or triggers.
- DDL statements on events are prohibited while a `LOCK TABLES` statement is in effect.

- Event timings using the intervals `YEAR`, `QUARTER`, `MONTH`, and `YEAR_MONTH` are resolved in months; those using any other interval are resolved in seconds. There is no way to cause events scheduled to occur at the same second to execute in a given order. In addition—due to rounding, the nature of threaded applications, and the fact that a nonzero length of time is required to create events and to signal their execution—events may be delayed by as much as 1 or 2 seconds. However, the time shown in the `INFORMATION_SCHEMA.EVENTS` table's `LAST_EXECUTED` column or the `mysql.event` table's `last_executed` column is always accurate to within one second of the actual event execution time. (See also Bug #16522.)
- Each execution of the statements contained in the body of an event takes place in a new connection; thus, these statements have no effect in a given user session on the server's statement counts such as `Com_select` and `Com_insert` that are displayed by `SHOW STATUS`. However, such counts are updated in the global scope. (Bug #16422)
- Events do not support times later than the end of the Unix Epoch; this is approximately the beginning of the year 2038. Such dates are specifically not permitted by the Event Scheduler. (Bug #16396)
- References to stored functions, user-defined functions, and tables in the `ON SCHEDULE` clauses of `CREATE EVENT` and `ALTER EVENT` statements are not supported. These sorts of references are not permitted. (See Bug #22830 for more information.)

## Stored Programs in NDB Cluster

While stored procedures, stored functions, triggers, and scheduled events are all supported by tables using the `NDB` storage engine, you must keep in mind that these do *not* propagate automatically between MySQL Servers acting as Cluster SQL nodes. This is because of the following:

- Stored routine definitions are kept in tables in the `mysql` system database using the `MyISAM` storage engine, and so do not participate in clustering.
- The `.TRN` and `.TRG` files containing trigger definitions are not read by the `NDB` storage engine, and are not copied between Cluster nodes.

Any stored routine or trigger that interacts with NDB Cluster tables must be re-created by running the appropriate `CREATE PROCEDURE`, `CREATE FUNCTION`, or `CREATE TRIGGER` statements on each MySQL Server that participates in the cluster where you wish to use the stored routine or trigger. Similarly, any changes to existing stored routines or triggers must be carried out explicitly on all Cluster SQL nodes, using the appropriate `ALTER` or `DROP` statements on each MySQL Server accessing the cluster.

### Warning

Do *not* attempt to work around the issue described in the first item mentioned previously by converting any `mysql` database tables to use the `NDB` storage engine. *Altering the system tables in the mysql database is not supported* and is very likely to produce undesirable results.

## 23.9 Restrictions on Views

The maximum number of tables that can be referenced in the definition of a view is 61.

View processing is not optimized:

- It is not possible to create an index on a view.
- Indexes can be used for views processed using the merge algorithm. However, a view that is processed with the temptable algorithm is unable to take advantage of indexes on its underlying tables (although indexes can be used during generation of the temporary tables).

Before MySQL 5.7.7, subqueries cannot be used in the `FROM` clause of a view.

There is a general principle that you cannot modify a table and select from the same table in a subquery. See [Section 13.2.10.12, “Restrictions on Subqueries”](#).

The same principle also applies if you select from a view that selects from the table, if the view selects from the table in a subquery and the view is evaluated using the merge algorithm. Example:

```
CREATE VIEW v1 AS
SELECT * FROM t2 WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t2.a);

UPDATE t1, v2 SET t1.a = 1 WHERE t1.b = v2.b;
```

If the view is evaluated using a temporary table, you *can* select from the table in the view subquery and still modify that table in the outer query. In this case the view is stored in a temporary table and thus you are not really selecting from the table in a subquery and modifying it “at the same time.” (This is another reason you might wish to force MySQL to use the temptable algorithm by specifying `ALGORITHM = TEMPTABLE` in the view definition.)

You can use `DROP TABLE` or `ALTER TABLE` to drop or alter a table that is used in a view definition. No warning results from the `DROP` or `ALTER` operation, even though this invalidates the view. Instead, an error occurs later, when the view is used. `CHECK TABLE` can be used to check for views that have been invalidated by `DROP` or `ALTER` operations.

With regard to view updatability, the overall goal for views is that if any view is theoretically updatable, it should be updatable in practice. MySQL as quickly as possible. Many theoretically updatable views can be updated now, but limitations still exist. For details, see [Section 23.5.3, “Updatable and Insertable Views”](#).

There exists a shortcoming with the current implementation of views. If a user is granted the basic privileges necessary to create a view (the `CREATE VIEW` and `SELECT` privileges), that user cannot call `SHOW CREATE VIEW` on that object unless the user is also granted the `SHOW VIEW` privilege.

That shortcoming can lead to problems backing up a database with `mysqldump`, which may fail due to insufficient privileges. This problem is described in Bug #22062.

The workaround to the problem is for the administrator to manually grant the `SHOW VIEW` privilege to users who are granted `CREATE VIEW`, since MySQL doesn't grant it implicitly when views are created.

Views do not have indexes, so index hints do not apply. Use of index hints when selecting from a view is not permitted.

`SHOW CREATE VIEW` displays view definitions using an `AS alias_name` clause for each column. If a column is created from an expression, the default alias is the expression text, which can be quite long. Aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters). As a result, views created from the output of `SHOW CREATE VIEW` fail if any column alias exceeds 64 characters. This can cause problems in the following circumstances for views with too-long aliases:

- View definitions fail to replicate to newer replicas that enforce the column-length restriction.
- Dump files created with `mysqldump` cannot be loaded into servers that enforce the column-length restriction.

A workaround for either problem is to modify each problematic view definition to use aliases that provide shorter column names. Then the view replicates properly, and can be dumped and reloaded without causing an error. To modify the definition, drop and create the view again with `DROP VIEW` and `CREATE VIEW`, or replace the definition with `CREATE OR REPLACE VIEW`.

For problems that occur when reloading view definitions in dump files, another workaround is to edit the dump file to modify its `CREATE VIEW` statements. However, this does not change the original view definitions, which may cause problems for subsequent dump operations.

---

- [Performance Considerations](#)
- [Standards Considerations](#)
- [Conventions in the INFORMATION\\_SCHEMA Reference Sections](#)
- [Related Information](#)

## INFORMATION\_SCHEMA Usage Notes

[INFORMATION\\_SCHEMA](#) is a database within each MySQL instance, the place that stores information about all the other databases that the MySQL server maintains. The [INFORMATION\\_SCHEMA](#) database

contains several read-only tables. They are actually views, not base tables, so there are no files associated with them, and you cannot set triggers on them. Also, there is no database directory with that name.

Although you can select `INFORMATION_SCHEMA` as the default database with a `USE` statement, you can only read the contents of tables, not perform `INSERT`, `UPDATE`, or `DELETE` operations on them.

Here is an example of a statement that retrieves information from `INFORMATION_SCHEMA`:

```
mysql> SELECT table_name, table_type, engine
 FROM information_schema.tables
 WHERE table_schema = 'db5'
 ORDER BY table_name;
+-----+-----+-----+
| table_name | table_type | engine |
+-----+-----+-----+
| fk | BASE TABLE | InnoDB |
| fk2 | BASE TABLE | InnoDB |
| goto | BASE TABLE | MyISAM |
| into | BASE TABLE | MyISAM |
| k | BASE TABLE | MyISAM |
| kurs | BASE TABLE | MyISAM |
| loop | BASE TABLE | MyISAM |
| pk | BASE TABLE | InnoDB |
| t | BASE TABLE | MyISAM |
| t2 | BASE TABLE | MyISAM |
| t3 | BASE TABLE | MyISAM |
| t7 | BASE TABLE | MyISAM |
| tables | BASE TABLE | MyISAM |
| v | VIEW | NULL |
| v2 | VIEW | NULL |
| v3 | VIEW | NULL |
| v56 | VIEW | NULL |
+-----+-----+-----+
17 rows in set (0.01 sec)
```

Explanation: The statement requests a list of all the tables in database `db5`, showing just three pieces of information: the name of the table, its type, and its storage engine.

## Character Set Considerations

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns.

Because some MySQL objects are represented as files, searches in `INFORMATION_SCHEMA` string columns can be affected by file system case sensitivity. For more information, see [Section 10.8.7, “Using Collation in INFORMATION\\_SCHEMA Searches”](#).

## `INFORMATION_SCHEMA` as Alternative to `SHOW` Statements

The `SELECT ... FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules, because all access is done on tables.
- You can use the familiar syntax of the `SELECT` statement, and only need to learn some table and column names.
- The implementor need not worry about adding keywords.
- You can filter, sort, concatenate, and transform the results from `INFORMATION_SCHEMA` queries into whatever format your application needs, such as a data structure or a text representation to parse.

- This technique is more interoperable with other database systems. For example, Oracle Database users are familiar with querying tables in the Oracle data dictionary.

Because `SHOW` is familiar and widely used, the `SHOW` statements remain as an alternative. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as described in Section 24.8, “Extensions to SHOW Statements”.

## INFORMATION\_SCHEMA and Privileges

For most `INFORMATION_SCHEMA` tables, each MySQL user has the right to access them, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the `INFORMATION_SCHEMA ROUTINES` table), users who have insufficient privileges see `NULL`. Some tables have different privilege requirements; for these, the requirements are mentioned in the applicable table descriptions. For example, `InnoDB` tables (tables with names that begin with `INNODB_`) require the `PROCESS` privilege.

The same privileges apply to selecting information from `INFORMATION_SCHEMA` and viewing the same information through `SHOW` statements. In either case, you must have some privilege on an object to see information about it.

## Performance Considerations

`INFORMATION_SCHEMA` queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use `EXPLAIN`. For information about using `EXPLAIN` output to tune `INFORMATION_SCHEMA` queries, see Section 8.2.3, “Optimizing `INFORMATION_SCHEMA` Queries”.

## Standards Considerations

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such added column is the `ENGINE` column in the `INFORMATION_SCHEMA TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: <https://web.archive.org/web/20070428032454/http://www.dbazine.com/db2/db2-disarticles/gulutzan5>.

## Conventions in the INFORMATION\_SCHEMA Reference Sections

The following sections describe each of the tables and columns in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA Name`” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW Name`” indicates the equivalent field name in the closest `SHOW` statement, if there is one.

- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

Many sections indicate what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`. For `SHOW` statements that display information for the default database if you omit a `FROM db_name` clause, you can often select information for the default database by adding an `AND TABLE_SCHEMA = SCHEMA()` condition to the `WHERE` clause of a query that retrieves information from an `INFORMATION_SCHEMA` table.

## Related Information

| INNODB_CMPMEM_RESET             | Status for compressed pages within InnoDB buffer pool                                       |            |            |
| INNODB_FT_BEING_DELETED         | Snapshot of INNODB_FT_DELETED table                                                         |            |            |
| INNODB_FT_CONFIG                | Metadata for InnoDB table FULLTEXT index and associated processing                          |            |            |
| INNODB_FT_DEFAULT_STOPWORD      | Default list of stopwords for InnoDB FULLTEXT indexes                                       |            |            |
| INNODB_FT_DELETED               | Rows deleted from InnoDB table FULLTEXT index                                               |            |            |
| INNODB_FT_INDEX_CACHED_TOKENS   | Token information for newly inserted rows in InnoDB FULLTEXT index                          |            |            |
| INNODB_FT_INDEX_INVERTED_TOKENS | Inverted index information for processing text searches against InnoDB table FULLTEXT index |            |            |
| INNODB_LOCK_WAITS               | InnoDB transaction lock-wait information                                                    | 5.7.14     |            |
| INNODB_LOCKS                    | InnoDB transaction lock information                                                         | 5.7.14     |            |
| INNODB_METRICS                  | InnoDB performance information                                                              |            |            |
| INNODB_SYS_COLUMNS              | Columns in each InnoDB table                                                                |            |            |
| INNODB_SYS_DATAFILE             | Data file path information for InnoDB file-per-table and general tablespaces                |            |            |
| INNODB_SYS_FIELDS               | Key columns of InnoDB indexes                                                               |            |            |
| INNODB_SYS_FOREIGN              | InnoDB foreign-key metadata                                                                 |            |            |
| INNODB_SYS_FOREIGN_COLS         | InnoDB foreign-key column status information                                                |            |            |
| INNODB_SYS_INDEXES              | InnoDB index metadata                                                                       |            |            |
| INNODB_SYS_TABLES               | InnoDB table metadata                                                                       |            |            |
| INNODB_SYS_TABLESPACES          | InnoDB file-per-table, general, and undo tablespace metadata                                |            |            |
| INNODB_SYS_TABLESTATUS          | InnoDB table low-level status information                                                   |            |            |
| INNODB_SYS_VIRTUAL              | InnoDB virtual generated column metadata                                                    |            |            |
| INNODB_TEMP_TABLE_INFO          | Information about active user-created InnoDB temporary tables                               |            |            |
| INNODB_TRX                      | Active InnoDB transaction information                                                       |            |            |
| KEY_COLUMN_USAGE                | Which key columns have constraints                                                          |            |            |
| MYSQL_FIREWALL_USER             | Firewall in-memory data for account profiles                                                |            |            |
| MYSQL_FIREWALL_WHITELIST        | Firewall in-memory data for account profile allowlists                                      |            |            |
| ndb_transid_mysql               | InnoDB transaction information                                                              |            |            |
| OPTIMIZER_TRACE                 | Information produced by optimizer trace activity                                            |            |            |
| PARAMETERS                      | Stored routine parameters and stored function return values                                 |            |            |

| Name                    | Description                                   | Introduced | Deprecated |
|-------------------------|-----------------------------------------------|------------|------------|
| PARTITIONS              | Table partition information                   |            |            |
| PLUGINS                 | Plugin information                            |            |            |
| PROCESSLIST             | Information about currently executing threads |            |            |
| PROFILING               | Statement profiling information               |            |            |
| REFERENTIAL_CONSTRAINTS | Foreign key information                       |            |            |
| ROUTINES                | Stored routine information                    |            |            |
| SCHEMA_PRIVILEGES       | Privileges defined on schemas                 |            |            |
| SCHEMATA                | Schema information                            |            |            |
| SESSION_STATUS          | Status variables for current session          |            |            |
| SESSION_VARIABLES       | System variables for current session          |            |            |
| STATISTICS              | Table index statistics                        |            |            |
| TABLE_CONSTRAINTS       | Which tables have constraints                 |            |            |
| TABLE_PRIVILEGES        | Privileges defined on tables                  |            |            |
| TABLES                  | Table information                             |            |            |
| TABLESPACES             | Tablespace information                        |            |            |
| TP_THREAD_GROUP_STATE   | Thread pool thread group states               |            |            |
| TP_THREAD_GROUP_STATS   | Thread pool thread group statistics           |            |            |
| TP_THREAD_STATE         | Thread pool thread information                |            |            |
| TRIGGERS                | Trigger information                           |            |            |
| USER_PRIVILEGES         | Privileges defined globally per user          |            |            |
| VIEWS                   | View information                              |            |            |

## 24.3 INFORMATION\_SCHEMA General Tables

The following sections describe what may be denoted as the “general” set of [INFORMATION\\_SCHEMA](#) tables. These are the tables not associated with particular storage engines, components, or plugins.

### 24.3.1 INFORMATION\_SCHEMA General Table Reference

The following table summarizes [INFORMATION\\_SCHEMA](#) general tables. For greater detail, see the individual table descriptions.

**Table 24.2 INFORMATION\_SCHEMA General Tables**

| Name                                  | Description                                |
|---------------------------------------|--------------------------------------------|
| CHARACTER_SETS                        | Available character sets                   |
| COLLATION_CHARACTER_SET_APPLICABILITY | Character set applicable to each collation |
| COLLATIONS                            | Collations for each character set          |
| COLUMN_PRIVILEGES                     | Privileges defined on columns              |
| COLUMNS                               | Columns in each table                      |
| ENGINES                               | Storage engine properties                  |
| EVENTS                                | Event Manager events                       |
| FILES                                 | Files that store tablespace data           |
| GLOBAL_STATUS                         | Global status variables                    |

| Name                    | Description                                                 |
|-------------------------|-------------------------------------------------------------|
| GLOBAL_VARIABLES        | Global system variables                                     |
| KEY_COLUMN_USAGE        | Which key columns have constraints                          |
| ndb_transid_mysql_conn  | NDB transaction information                                 |
| OPTIMIZER_TRACE         | Information produced by optimizer trace activity            |
| PARAMETERS              | Stored routine parameters and stored function return values |
| PARTITIONS              | Table partition information                                 |
| PLUGINS                 | Plugin information                                          |
| PROCESSLIST             | Information about currently executing threads               |
| PROFILING               | Statement profiling information                             |
| REFERENTIAL_CONSTRAINTS | Foreign key information                                     |
| ROUTINES                | Stored routine information                                  |
| SCHEMA_PRIVILEGES       | Privileges defined on schemas                               |
| SCHEMATA                | Schema information                                          |
| SESSION_STATUS          | Status variables for current session                        |
| SESSION_VARIABLES       | System variables for current session                        |
| STATISTICS              | Table index statistics                                      |
| TABLE_CONSTRAINTS       | Which tables have constraints                               |
| TABLE_PRIVILEGES        | Privileges defined on tables                                |
| TABLES                  | Table information                                           |
| TABLESPACES             | Tablespace information                                      |
| TRIGGERS                | Trigger information                                         |
| USER_PRIVILEGES         | Privileges defined globally per user                        |
| VIEWS                   | View information                                            |

### 24.3.2 The INFORMATION\_SCHEMA CHARACTER\_SETS Table

The `CHARACTER_SETS` table provides information about available character sets.

The `CHARACTER_SETS` table has these columns:

- `CHARACTER_SET_NAME`

The character set name.

- `DEFAULT_COLLATE_NAME`

The default collation for the character set.

- `DESCRIPTION`

A description of the character set.

- `MAXLEN`

The maximum number of bytes required to store one character.

### Notes

Character set information is also available from the `SHOW CHARACTER SET` statement. See Section 13.7.5.3, “[SHOW CHARACTER SET Statement](#)”. The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
[WHERE CHARACTER_SET_NAME LIKE 'wild']

SHOW CHARACTER SET
[LIKE 'wild']
```

### 24.3.3 The INFORMATION\_SCHEMA COLLATIONS Table

The `COLLATIONS` table provides information about collations for each character set.

The `COLLATIONS` table has these columns:

- `COLLATION_NAME`

The collation name.

- `CHARACTER_SET_NAME`

The name of the character set with which the collation is associated.

- `ID`

The collation ID.

- `IS_DEFAULT`

Whether the collation is the default for its character set.

- `IS_COMPILED`

Whether the character set is compiled into the server.

- `SORTLEN`

This is related to the amount of memory required to sort strings expressed in the character set.

#### Notes

Collation information is also available from the `SHOW COLLATION` statement. See [Section 13.7.5.4, "SHOW COLLATION Statement"](#). The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
[WHERE COLLATION_NAME LIKE 'wild']

SHOW COLLATION
[LIKE 'wild']
```

### 24.3.4 The INFORMATION\_SCHEMA COLLATION\_CHARACTER\_SET\_APPLICABILITY Table

The `COLLATION_CHARACTER_SET_APPLICABILITY` table indicates what character set is applicable for what collation.

The `COLLATION_CHARACTER_SET_APPLICABILITY` table has these columns:

- `COLLATION_NAME`

The collation name.

- `CHARACTER_SET_NAME`

The name of the character set with which the collation is associated.

## Notes

The `COLLATION_CHARACTER_SET_APPLICABILITY` columns are equivalent to the first two columns displayed by the `SHOW COLLATION` statement.

### 24.3.5 The INFORMATION\_SCHEMA COLUMNS Table

The `COLUMNS` table provides information about columns in tables.

The `COLUMNS` table has these columns:

- `TABLE_CATALOG`

The name of the catalog to which the table containing the column belongs. This value is always `def`.

- `TABLE_SCHEMA`

The name of the schema (database) to which the table containing the column belongs.

- `TABLE_NAME`

The name of the table containing the column.

- `COLUMN_NAME`

The name of the column.

- `ORDINAL_POSITION`

The position of the column within the table. `ORDINAL_POSITION` is necessary because you might want to say `ORDER BY ORDINAL_POSITION`. Unlike `SHOW COLUMNS`, `SELECT` from the `COLUMNS` table does not have automatic ordering.

- `COLUMN_DEFAULT`

The default value for the column. This is `NULL` if the column has an explicit default of `NULL`, or if the column definition includes no `DEFAULT` clause.

- `IS_NULLABLE`

The column nullability. The value is `YES` if `NULL` values can be stored in the column, `NO` if not.

- `DATA_TYPE`

The column data type.

The `DATA_TYPE` value is the type name only with no other information. The `COLUMN_TYPE` value contains the type name and possibly other information such as the precision or length.

- `CHARACTER_MAXIMUM_LENGTH`

For string columns, the maximum length in characters.

- `CHARACTER_OCTET_LENGTH`

For string columns, the maximum length in bytes.

- `NUMERIC_PRECISION`

For numeric columns, the numeric precision.

- `NUMERIC_SCALE`

For numeric columns, the numeric scale.

- **DATETIME\_PRECISION**

For temporal columns, the fractional seconds precision.

- **CHARACTER\_SET\_NAME**

For character string columns, the character set name.

- **COLLATION\_NAME**

For character string columns, the collation name.

- **COLUMN\_TYPE**

The column data type.

The **DATA\_TYPE** value is the type name only with no other information. The **COLUMN\_TYPE** value contains the type name and possibly other information such as the precision or length.

- **COLUMN\_KEY**

Whether the column is indexed:

- If **COLUMN\_KEY** is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
- If **COLUMN\_KEY** is **PRI**, the column is a **PRIMARY KEY** or is one of the columns in a multiple-column **PRIMARY KEY**.
- If **COLUMN\_KEY** is **UNI**, the column is the first column of a **UNIQUE** index. (A **UNIQUE** index permits multiple **NULL** values, but you can tell whether the column permits **NULL** by checking the **Null** column.)
- If **COLUMN\_KEY** is **MUL**, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

If more than one of the **COLUMN\_KEY** values applies to a given column of a table, **COLUMN\_KEY** displays the one with the highest priority, in the order **PRI**, **UNI**, **MUL**.

A **UNIQUE** index may be displayed as **PRI** if it cannot contain **NULL** values and there is no **PRIMARY KEY** in the table. A **UNIQUE** index may display as **MUL** if several columns form a composite **UNIQUE** index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

- **EXTRA**

Any additional information that is available about a given column. The value is nonempty in these cases:

- **auto\_increment** for columns that have the **AUTO\_INCREMENT** attribute.
- **on update CURRENT\_TIMESTAMP** for **TIMESTAMP** or **DATETIME** columns that have the **ON UPDATE CURRENT\_TIMESTAMP** attribute.
- **STORED GENERATED** or **VIRTUAL GENERATED** for generated columns.

- **PRIVILEGES**

The privileges you have for the column.

- **COLUMN\_COMMENT**

Any comment included in the column definition.

- **GENERATION\_EXPRESSION**

For generated columns, displays the expression used to compute column values. Empty for nongenerated columns. For information about generated columns, see [Section 13.1.18.7, “CREATE TABLE and Generated Columns”](#).

## Notes

- In `SHOW COLUMNS`, the `Type` display includes values from several different `COLUMNS` columns.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multibyte character sets.
- `CHARACTER_SET_NAME` can be derived from `COLLATION_NAME`. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the `COLLATION_NAME` column a value of `latin1_swedish_ci`, the character set is what is before the first underscore: `latin1`.

Column information is also available from the `SHOW COLUMNS` statement. See [Section 13.7.5.5, “SHOW COLUMNS Statement”](#). The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
 FROM INFORMATION_SCHEMA.COLUMNS
 WHERE table_name = 'tbl_name'
 [AND table_schema = 'db_name']
 [AND column_name LIKE 'wild']

SHOW COLUMNS
 FROM tbl_name
 [FROM db_name]
 [LIKE 'wild']
```

## 24.3.6 The INFORMATION\_SCHEMA COLUMN\_PRIVILEGES Table

The `COLUMN_PRIVILEGES` table provides information about column privileges. It takes its values from the `mysql.columns_priv` system table.

The `COLUMN_PRIVILEGES` table has these columns:

- **GRANTEE**

The name of the account to which the privilege is granted, in '`user_name'@'host_name'` format.

- **TABLE\_CATALOG**

The name of the catalog to which the table containing the column belongs. This value is always `def`.

- **TABLE\_SCHEMA**

The name of the schema (database) to which the table containing the column belongs.

- **TABLE\_NAME**

The name of the table containing the column.

- **COLUMN\_NAME**

The name of the column.

- **PRIVILEGE\_TYPE**

The privilege granted. The value can be any privilege that can be granted at the column level; see [Section 13.7.1.4, “GRANT Statement”](#). Each row lists a single privilege, so there is one row per column privilege held by the grantee.

In the output from `SHOW FULL COLUMNS`, the privileges are all in one column and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.

- `IS_GRANTABLE`

`YES` if the user has the `GRANT OPTION` privilege, `NO` otherwise. The output does not list `GRANT OPTION` as a separate row with `PRIVILEGE_TYPE='GRANT OPTION'`.

## Notes

- `COLUMN_PRIVILEGES` is a nonstandard `INFORMATION_SCHEMA` table.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
SHOW GRANTS ...
```

### 24.3.7 The INFORMATION\_SCHEMA ENGINES Table

The `ENGINES` table provides information about storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is.

The `ENGINES` table has these columns:

- `ENGINE`

The name of the storage engine.

- `SUPPORT`

The server's level of support for the storage engine, as shown in the following table.

| Value                 | Meaning                                                 |
|-----------------------|---------------------------------------------------------|
| <code>YES</code>      | The engine is supported and is active                   |
| <code>DEFAULT</code>  | Like <code>YES</code> , plus this is the default engine |
| <code>NO</code>       | The engine is not supported                             |
| <code>DISABLED</code> | The engine is supported but has been disabled           |

A value of `NO` means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of `DISABLED` occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log should contain a reason indicating why the option is disabled. See [Section 5.4.2, “The Error Log”](#).

You might also see `DISABLED` for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option. For the `NDB` storage engine, `DISABLED` means the server was compiled with support for NDB Cluster, but was not started with the `--ndbcluster` option.

All MySQL servers support `MyISAM` tables. It is not possible to disable `MyISAM`.

- `COMMENT`

A brief description of the storage engine.

- `TRANSACTIONS`

Whether the storage engine supports transactions.

- [XA](#)

Whether the storage engine supports XA transactions.

- [SAVEPOINTS](#)

Whether the storage engine supports savepoints.

## Notes

- [ENGINES](#) is a nonstandard [INFORMATION\\_SCHEMA](#) table.

Storage engine information is also available from the [SHOW ENGINES](#) statement. See [Section 13.7.5.16, “SHOW ENGINES Statement”](#). The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.ENGINES
SHOW ENGINES
```

## 24.3.8 The INFORMATION\_SCHEMA EVENTS Table

The [EVENTS](#) table provides information about Event Manager events, which are discussed in [Section 23.4, “Using the Event Scheduler”](#).

The [EVENTS](#) table has these columns:

- [EVENT\\_CATALOG](#)

The name of the catalog to which the event belongs. This value is always [def](#).

- [EVENT\\_SCHEMA](#)

The name of the schema (database) to which the event belongs.

- [EVENT\\_NAME](#)

The name of the event.

- [DEFINER](#)

The account named in the [DEFINER](#) clause (often the user who created the event), in '[user\\_name](#)'@'[host\\_name](#)' format.

- [TIME\\_ZONE](#)

The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is [SYSTEM](#).

- [EVENT\\_BODY](#)

The language used for the statements in the event's [DO](#) clause. The value is always [SQL](#).

- [EVENT\\_DEFINITION](#)

The text of the SQL statement making up the event's [DO](#) clause; in other words, the statement executed by this event.

- [EVENT\\_TYPE](#)

The event repetition type, either [ONE TIME](#) (transient) or [RECURRING](#) (repeating).

- [EXECUTE\\_AT](#)

For a one-time event, this is the `DATETIME` value specified in the `AT` clause of the `CREATE EVENT` statement used to create the event, or of the last `ALTER EVENT` statement that modified the event. The value shown in this column reflects the addition or subtraction of any `INTERVAL` value included in the event's `AT` clause. For example, if an event is created using `ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR`, and the event was created at 2018-02-09 14:05:30, the value shown in this column would be '`2018-02-10 20:05:30`'. If the event's timing is determined by an `EVERY` clause instead of an `AT` clause (that is, if the event is recurring), the value of this column is `NULL`.

- [INTERVAL\\_VALUE](#)

For a recurring event, the number of intervals to wait between event executions. For a transient event, the value is always `NULL`.

- [INTERVAL\\_FIELD](#)

The time units used for the interval which a recurring event waits before repeating. For a transient event, the value is always `NULL`.

- [SQL\\_MODE](#)

The SQL mode in effect when the event was created or altered, and under which the event executes. For the permitted values, see [Section 5.1.10, “Server SQL Modes”](#).

- [STARTS](#)

The start date and time for a recurring event. This is displayed as a `DATETIME` value, and is `NULL` if no start date and time are defined for the event. For a transient event, this column is always `NULL`. For a recurring event whose definition includes a `STARTS` clause, this column contains the corresponding `DATETIME` value. As with the `EXECUTE_AT` column, this value resolves any expressions used. If there is no `STARTS` clause affecting the timing of the event, this column is `NULL`.

- [ENDS](#)

For a recurring event whose definition includes a `ENDS` clause, this column contains the corresponding `DATETIME` value. As with the `EXECUTE_AT` column, this value resolves any expressions used. If there is no `ENDS` clause affecting the timing of the event, this column is `NULL`.

- [STATUS](#)

The event status. One of `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`. `SLAVESIDE_DISABLED` indicates that the creation of the event occurred on another MySQL server acting as a replication source and replicated to the current MySQL server which is acting as a replica, but the event is not presently being executed on the replica. For more information, see [Section 16.4.1.16, “Replication of Invoked Features”](#). information.

- [ON\\_COMPLETION](#)

One of the two values `PRESERVE` or `NOT PRESERVE`.

- [CREATED](#)

The date and time when the event was created. This is a `TIMESTAMP` value.

- [LAST\\_ALTERED](#)

The date and time when the event was last modified. This is a `TIMESTAMP` value. If the event has not been modified since its creation, this value is the same as the `CREATED` value.

- [LAST\\_EXECUTED](#)

The date and time when the event last executed. This is a `DATETIME` value. If the event has never executed, this column is `NULL`.

`LAST_EXECUTED` indicates when the event started. As a result, the `ENDS` column is never less than `LAST_EXECUTED`.

- `EVENT_COMMENT`

The text of the comment, if the event has one. If not, this value is empty.

- `ORIGINATOR`

The server ID of the MySQL server on which the event was created; used in replication. This value may be updated by `ALTER EVENT` to the server ID of the server on which that statement occurs, if executed on a replication source. The default value is 0.

- `CHARACTER_SET_CLIENT`

The session value of the `character_set_client` system variable when the event was created.

- `COLLATION_CONNECTION`

The session value of the `collation_connection` system variable when the event was created.

- `DATABASE_COLLATION`

The collation of the database with which the event is associated.

## Notes

- `EVENTS` is a nonstandard `INFORMATION_SCHEMA` table.
- Times in the `EVENTS` table are displayed using the event time zone, the current session time zone, or UTC, as described in [Section 23.4.4, “Event Metadata”](#).
- For more information about `SLAVESIDE_DISABLED` and the `ORIGINATOR` column, see [Section 16.4.1.16, “Replication of Invoked Features”](#).

## Example

Suppose that the user '`jon'@'ghidora'`' creates an event named `e_daily`, and then modifies it a few minutes later using an `ALTER EVENT` statement, as shown here:

```
DELIMITER |

CREATE EVENT e_daily
 ON SCHEDULE
 EVERY 1 DAY
 COMMENT 'Saves total number of sessions then clears the table each day'
 DO
 BEGIN
 INSERT INTO site_activity.totals (time, total)
 SELECT CURRENT_TIMESTAMP, COUNT(*)
 FROM site_activity.sessions;
 DELETE FROM site_activity.sessions;
 END |

DELIMITER ;

ALTER EVENT e_daily
 ENABLE;
```

(Note that comments can span multiple lines.)

This user can then run the following `SELECT` statement, and obtain the output shown:

```

mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
 WHERE EVENT_NAME = 'e_daily'
 AND EVENT_SCHEMA = 'myschema'\G

***** 1. row *****
EVENT_CATALOG: def
EVENT_SCHEMA: myschema
EVENT_NAME: e_daily
DEFINER: jon@ghidora
TIME_ZONE: SYSTEM
EVENT_BODY: SQL
EVENT_DEFINITION: BEGIN
 INSERT INTO site_activity.totals (time, total)
 SELECT CURRENT_TIMESTAMP, COUNT(*)
 FROM site_activity.sessions;
 DELETE FROM site_activity.sessions;
END
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 1
INTERVAL_FIELD: DAY
SQL_MODE: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
NO_ZERO_IN_DATE,NO_ZERO_DATE,
ERROR_FOR_DIVISION_BY_ZERO,
NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION
STARTS: 2018-08-08 11:06:34
ENDS: NULL
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2018-08-08 11:06:34
LAST_ALTERED: 2018-08-08 11:06:34
LAST_EXECUTED: 2018-08-08 16:06:34
EVENT_COMMENT: Saves total number of sessions then clears the
table each day
ORIGINATOR: 1
CHARACTER_SET_CLIENT: utf8
COLLATION_CONNECTION: utf8_general_ci
DATABASE_COLLATION: latin1_swedish_ci

```

Event information is also available from the `SHOW EVENTS` statement. See [Section 13.7.5.18, “SHOW EVENTS Statement”](#). The following statements are equivalent:

```

SELECT
 EVENT_SCHEMA, EVENT_NAME, DEFINER, TIME_ZONE, EVENT_TYPE, EXECUTE_AT,
 INTERVAL_VALUE, INTERVAL_FIELD, STARTS, ENDS, STATUS, ORIGINATOR,
 CHARACTER_SET_CLIENT, COLLATION_CONNECTION, DATABASE_COLLATION
FROM INFORMATION_SCHEMA.EVENTS
WHERE table_schema = 'db_name'
[AND column_name LIKE 'wild']

SHOW EVENTS
[FROM db_name]
[LIKE 'wild']

```

### 24.3.9 The INFORMATION\_SCHEMA FILES Table

The `FILES` table provides information about the files in which MySQL tablespace data is stored.

The `FILES` table provides information about InnoDB data files. In NDB Cluster, this table also provides information about the files in which NDB Cluster Disk Data tables are stored. For additional information specific to InnoDB, see [InnoDB Notes](#), later in this section; for additional information specific to NDB Cluster, see [NDB Notes](#).

The `FILES` table has these columns:

- `FILE_ID`

For InnoDB: The tablespace ID, also referred to as the `space_id` or `fil_space_t::id`.

For NDB: A file identifier. `FILE_ID` column values are auto-generated.

- **FILE\_NAME**

For **InnoDB**: The name of the data file. File-per-table and general tablespaces have an `.ibd` file name extension. Undo tablespaces are prefixed by `undo`. The system tablespace is prefixed by `ibdata`. Temporary tablespaces are prefixed by `ibtmp`. The file name includes the file path, which may be relative to the MySQL data directory (the value of the `datadir` system variable).

For **NDB**: The name of an **UNDO** log file created by `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP`, or of a data file created by `CREATE TABLESPACE` or `ALTER TABLESPACE`.

- **FILE\_TYPE**

For **InnoDB**: The tablespace file type. There are three possible file types for **InnoDB** files. **TABLESPACE** is the file type for any system, general, or file-per-table tablespace file that holds tables, indexes, or other forms of user data. **TEMPORARY** is the file type for temporary tablespaces. **UNDO LOG** is the file type for undo tablespaces, which hold undo records.

For **NDB**: One of the values **UNDO LOG**, **DATAFILE**, or **TABLESPACE**.

- **TABLESPACE\_NAME**

The name of the tablespace with which the file is associated.

- **TABLE\_CATALOG**

This value is always empty.

- **TABLE\_SCHEMA**

This is always `NULL`.

- **TABLE\_NAME**

This is always `NULL`.

- **LOGFILE\_GROUP\_NAME**

For **InnoDB**: This is always `NULL`.

For **NDB**: The name of the log file group to which the log file or data file belongs.

- **LOGFILE\_GROUP\_NUMBER**

For **InnoDB**: This is always `NULL`.

For **NDB**: For a Disk Data undo log file, the auto-generated ID number of the log file group to which the log file belongs. This is the same as the value shown for the `id` column in the `ndbinfo.dict_obj_info` table and the `log_id` column in the `ndbinfo.logspaces` and `ndbinfo.logsplaces` tables for this undo log file.

- **ENGINE**

For **InnoDB**: This is always **InnoDB**.

For **NDB**: This is always **ndbcluster**.

- **FULLTEXT\_KEYS**

This is always `NULL`.

- **DELETED\_ROWS**

This is always `NULL`.

- [UPDATE\\_COUNT](#)

This is always `NULL`.

- [FREE\\_EXTENTS](#)

For [InnoDB](#): The number of fully free extents in the current data file.

For [NDB](#): The number of extents which have not yet been used by the file.

- [TOTAL\\_EXTENTS](#)

For [InnoDB](#): The number of full extents used in the current data file. Any partial extent at the end of the file is not counted.

For [NDB](#): The total number of extents allocated to the file.

- [EXTENT\\_SIZE](#)

For [InnoDB](#): Extent size is 1048576 (1MB) for files with a 4KB, 8KB, or 16KB page size. Extent size is 2097152 bytes (2MB) for files with a 32KB page size, and 4194304 (4MB) for files with a 64KB page size. [FILES](#) does not report [InnoDB](#) page size. Page size is defined by the `innodb_page_size` system variable. Extent size information can also be retrieved from the `INNODB_SYS_TABLESPACES` table where `FILES.FILE_ID = INNODB_SYS_TABLESPACESSPACE`.

For [NDB](#): The size of an extent for the file in bytes.

- [INITIAL\\_SIZE](#)

For [InnoDB](#): The initial size of the file in bytes.

For [NDB](#): The size of the file in bytes. This is the same value that was used in the `INITIAL_SIZE` clause of the `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, or `ALTER TABLESPACE` statement used to create the file.

- [MAXIMUM\\_SIZE](#)

For [InnoDB](#): The maximum number of bytes permitted in the file. The value is `NULL` for all data files except for predefined system tablespace data files. Maximum system tablespace file size is defined by `innodb_data_file_path`. Maximum temporary tablespace file size is defined by `innodb_temp_data_file_path`. A `NULL` value for a predefined system tablespace data file indicates that a file size limit was not defined explicitly.

For [NDB](#): This value is always the same as the `INITIAL_SIZE` value.

- [AUTOEXTEND\\_SIZE](#)

The auto-extend size of the tablespace. For [NDB](#), `AUTOEXTEND_SIZE` is always `NULL`.

- [CREATION\\_TIME](#)

This is always `NULL`.

- [LAST\\_UPDATE\\_TIME](#)

This is always `NULL`.

- [LAST\\_ACCESS\\_TIME](#)

This is always `NULL`.

- [RECOVER\\_TIME](#)

This is always `NULL`.

- `TRANSACTION_COUNTER`

This is always `NULL`.

- `VERSION`

For `InnoDB`: This is always `NULL`.

For `NDB`: The version number of the file.

- `ROW_FORMAT`

For `InnoDB`: This is always `NULL`.

For `NDB`: One of `FIXED` or `DYNAMIC`.

- `TABLE_ROWS`

This is always `NULL`.

- `AVG_ROW_LENGTH`

This is always `NULL`.

- `DATA_LENGTH`

This is always `NULL`.

- `MAX_DATA_LENGTH`

This is always `NULL`.

- `INDEX_LENGTH`

This is always `NULL`.

- `DATA_FREE`

For `InnoDB`: The total amount of free space (in bytes) for the entire tablespace. Predefined system tablespaces, which include the system tablespace and temporary table tablespaces, may have one or more data files.

For `NDB`: This is always `NULL`.

- `CREATE_TIME`

This is always `NULL`.

- `UPDATE_TIME`

This is always `NULL`.

- `CHECK_TIME`

This is always `NULL`.

- `CHECKSUM`

This is always `NULL`.

- `STATUS`

For InnoDB: This value is [NORMAL](#) by default. InnoDB file-per-table tablespaces may report [IMPORTING](#), which indicates that the tablespace is not yet available.

For NDB: This is always [NORMAL](#).

- [EXTRA](#)

For InnoDB: This is always [NULL](#).

For NDB: This column shows which data node the data file or undo log file belongs to (each data node having its own copy of each file); for an undo log files, it also shows the size of the undo log buffer. Suppose that you use this statement on an NDB Cluster with four data nodes:

```
CREATE LOGFILE GROUP mygroup
 ADD UNDOFILE 'new_undo.dat'
 INITIAL_SIZE 2G
 ENGINE NDB;
```

After running the `CREATE LOGFILE GROUP` statement successfully, you should see a result similar to the one shown here for this query against the `FILES` table:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
 FROM INFORMATION_SCHEMA.FILES
 WHERE FILE_NAME = 'new_undo.dat';

+-----+-----+-----+
| LOGFILE_GROUP_NAME | FILE_TYPE | EXTRA |
+-----+-----+-----+
| mygroup | UNDO LOG | CLUSTER_NODE=5;UNDO_BUFFER_SIZE=8388608 |
| mygroup | UNDO LOG | CLUSTER_NODE=6;UNDO_BUFFER_SIZE=8388608 |
| mygroup | UNDO LOG | CLUSTER_NODE=7;UNDO_BUFFER_SIZE=8388608 |
| mygroup | UNDO LOG | CLUSTER_NODE=8;UNDO_BUFFER_SIZE=8388608 |
+-----+-----+-----+
```

## Notes

- `FILES` is a nonstandard [INFORMATION\\_SCHEMA](#) table.

### InnoDB Notes

The following notes apply to InnoDB data files.

- Data reported by `FILES` is reported from the InnoDB in-memory cache for open files. By comparison, `INNODB_SYS_DATAFILES` reports data from the `InnoDB SYS_DATAFILES` internal data dictionary table.
- The data reported by `FILES` includes temporary tablespace data. This data is not available in the `InnoDB SYS_DATAFILES` internal data dictionary table, and is therefore not reported by `INNODB_SYS_DATAFILES`.
- Undo tablespace data is reported by `FILES`.
- The following query returns all data pertinent to InnoDB tablespaces.

```
SELECT
 FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS,
 TOTAL_EXTENTS, EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE,
 AUTOEXTEND_SIZE, DATA_FREE, STATUS
FROM INFORMATION_SCHEMA.FILES WHERE ENGINE='InnoDB' \G
```

### NDB Notes

- The `FILES` table provides information about Disk Data *files* only; you cannot use it for determining disk space allocation or availability for individual NDB tables. However, it is possible to see how much

space is allocated for each NDB table having data stored on disk—as well as how much remains available for storage of data on disk for that table—using `ndb_desc`.

- The `CREATION_TIME`, `LAST_UPDATE_TIME`, and `LAST_ACCESSED` values are as reported by the operating system, and are not supplied by the NDB storage engine. Where no value is provided by the operating system, these columns display `NULL`.
- The difference between the `TOTAL_EXTENTS` and `FREE_EXTENTS` columns is the number of extents currently in use by the file:

```
SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
 FROM INFORMATION_SCHEMA.FILES
 WHERE FILE_NAME = 'myfile.dat';
```

To approximate the amount of disk space in use by the file, multiply that difference by the value of the `EXTENT_SIZE` column, which gives the size of an extent for the file in bytes:

```
SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
 FROM INFORMATION_SCHEMA.FILES
 WHERE FILE_NAME = 'myfile.dat';
```

Similarly, you can estimate the amount of space that remains available in a given file by multiplying `FREE_EXTENTS` by `EXTENT_SIZE`:

```
SELECT FREE_EXTENTS * EXTENT_SIZE AS bytes_free
 FROM INFORMATION_SCHEMA.FILES
 WHERE FILE_NAME = 'myfile.dat';
```

### Important

The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of `EXTENT_SIZE`. That is, the larger `EXTENT_SIZE` becomes, the less accurate the approximations are.

It is also important to remember that once an extent is used, it cannot be freed again without dropping the data file of which it is a part. This means that deletes from a Disk Data table do *not* release disk space.

The extent size can be set in a `CREATE TABLESPACE` statement. For more information, see [Section 13.1.19, “CREATE TABLESPACE Statement”](#).

- An additional row is present in the `FILES` table following the creation of a logfile group. This row has `NULL` for the value of the `FILE_NAME` column and `0` for the value of the `FILE_ID` column; the value of the `FILE_TYPE` column is always `UNDO_LOG`, and that of the `STATUS` column is always `NORMAL`. The value of the `ENGINE` column for this row is always `ndbcluster`.

The `FREE_EXTENTS` column in this row shows the total number of free extents available to all undo files belonging to a given log file group whose name and number are shown in the `LOGFILE_GROUP_NAME` and `LOGFILE_GROUP_NUMBER` columns, respectively.

Suppose there are no existing log file groups on your NDB Cluster, and you create one using the following statement:

```
mysql> CREATE LOGFILE GROUP lgl
 ADD UNDOFILE 'undofile.dat'
 INITIAL_SIZE = 16M
 UNDO_BUFFER_SIZE = 1M
 ENGINE = NDB;
```

You can now see this `NULL` row when you query the `FILES` table:

```
mysql> SELECT DISTINCT
 FILE_NAME AS File,
```

## The INFORMATION\_SCHEMA.FILES Table

```
FREE_EXTENTS AS Free,
TOTAL_EXTENTS AS Total,
EXTENT_SIZE AS Size,
INITIAL_SIZE AS Initial
FROM INFORMATION_SCHEMA.FILES;

+-----+-----+-----+-----+
| File | Free | Total | Size | Initial |
+-----+-----+-----+-----+
| undofile.dat | NULL | 4194304 | 4 | 16777216 |
| NULL | 4184068 | NULL | 4 | NULL |
+-----+-----+-----+-----+
```

The total number of free extents available for undo logging is always somewhat less than the sum of the `TOTAL_EXTENTS` column values for all undo files in the log file group due to overhead required for maintaining the undo files. This can be seen by adding a second undo file to the log file group, then repeating the previous query against the `FILES` table:

```
mysql> ALTER LOGFILE GROUP lg1
 ADD UNDOFILE 'undofile02.dat'
 INITIAL_SIZE = 4M
 ENGINE = NDB;

mysql> SELECT DISTINCT
 FILE_NAME AS File,
 FREE_EXTENTS AS Free,
 TOTAL_EXTENTS AS Total,
 EXTENT_SIZE AS Size,
 INITIAL_SIZE AS Initial
 FROM INFORMATION_SCHEMA.FILES;

+-----+-----+-----+-----+
| File | Free | Total | Size | Initial |
+-----+-----+-----+-----+
| undofile.dat | NULL | 4194304 | 4 | 16777216 |
| undofile02.dat | NULL | 1048576 | 4 | 4194304 |
| NULL | 5223944 | NULL | 4 | NULL |
+-----+-----+-----+-----+
```

The amount of free space in bytes which is available for undo logging by Disk Data tables using this log file group can be approximated by multiplying the number of free extents by the initial size:

```
mysql> SELECT
 FREE_EXTENTS AS 'Free Extents',
 FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
 FROM INFORMATION_SCHEMA.FILES
 WHERE LOGFILE_GROUP_NAME = 'lg1'
 AND FILE_NAME IS NULL;

+-----+-----+
| Free Extents | Free Bytes |
+-----+-----+
| 5223944 | 20895776 |
+-----+-----+
```

If you create an NDB Cluster Disk Data table and then insert some rows into it, you can see approximately how much space remains for undo logging afterward, for example:

```
mysql> CREATE TABLESPACE ts1
 ADD DATAFILE 'data1.dat'
 USE LOGFILE GROUP lg1
 INITIAL_SIZE 512M
 ENGINE = NDB;

mysql> CREATE TABLE dd (
 c1 INT NOT NULL PRIMARY KEY,
 c2 INT,
 c3 DATE
)
 TABLESPACE ts1 STORAGE DISK
 ENGINE = NDB;

mysql> INSERT INTO dd VALUES
```

```
(NULL, 1234567890, '2007-02-02'),
(NULL, 1126789005, '2007-02-03'),
(NULL, 1357924680, '2007-02-04'),
(NULL, 1642097531, '2007-02-05');

mysql> SELECT
 FREE_EXTENTS AS 'Free Extents',
 FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
 FROM INFORMATION_SCHEMA.FILES
 WHERE LOGFILE_GROUP_NAME = 'lg1'
 AND FILE_NAME IS NULL;
+-----+-----+
| Free Extents | Free Bytes |
+-----+-----+
| 5207565 | 20830260 |
+-----+-----+
```

- An additional row is present in the `FILES` table for any NDB Cluster tablespace, whether or not any data files are associated with the tablespace. This row has `NULL` for the value of the `FILE_NAME` column, and the value of the `FILE_ID` column is always `0`. The value shown in the `FILE_TYPE` column is always `TABLESPACE`, and that of the `STATUS` column is always `NORMAL`. The value of the `ENGINE` column for this row is always `ndbcluster`.
- For additional information, and examples of creating and dropping NDB Cluster Disk Data objects, see [Section 21.5.10, “NDB Cluster Disk Data Tables”](#).
- As of MySQL 5.7.31, you must have the `PROCESS` privilege to query this table.

### 24.3.10 The INFORMATION\_SCHEMA GLOBAL\_STATUS and SESSION\_STATUS Tables

#### Note

The value of the `show_compatibility_56` system variable affects the information available from the tables described here. For details, see the description of that variable in [Section 5.1.7, “Server System Variables”](#).

#### Note

Information available from the tables described here is also available from the Performance Schema. The `INFORMATION_SCHEMA` tables are deprecated in preference to the Performance Schema tables and are removed in MySQL 8.0. For advice on migrating away from the `INFORMATION_SCHEMA` tables to the Performance Schema tables, see [Section 25.20, “Migrating to Performance Schema System and Status Variable Tables”](#).

The `GLOBAL_STATUS` and `SESSION_STATUS` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL STATUS` and `SHOW SESSION STATUS` statements (see [Section 13.7.5.35, “SHOW STATUS Statement”](#)).

#### Notes

- The `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(1024)`.

### 24.3.11 The INFORMATION\_SCHEMA GLOBAL\_VARIABLES and SESSION\_VARIABLES Tables

#### Note

The value of the `show_compatibility_56` system variable affects the information available from the tables described here. For details, see the description of that variable in [Section 5.1.7, “Server System Variables”](#).

**Note**

Information available from the tables described here is also available from the Performance Schema. The `INFORMATION_SCHEMA` tables are deprecated in preference to the Performance Schema tables and are removed in MySQL 8.0. For advice on migrating away from the `INFORMATION_SCHEMA` tables to the Performance Schema tables, see [Section 25.20, “Migrating to Performance Schema System and Status Variable Tables”](#).

The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL VARIABLES` and `SHOW SESSION VARIABLES` statements (see [Section 13.7.5.39, “SHOW VARIABLES Statement”](#)).

**Notes**

- The `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(1024)`. For variables with very long values that are not completely displayed, use `SELECT` as a workaround. For example:

```
SELECT @@GLOBAL.innodb_data_file_path;
```

### 24.3.12 The INFORMATION\_SCHEMA KEY\_COLUMN\_USAGE Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints.

The `KEY_COLUMN_USAGE` table has these columns:

- `CONSTRAINT_CATALOG`

The name of the catalog to which the constraint belongs. This value is always `def`.

- `CONSTRAINT_SCHEMA`

The name of the schema (database) to which the constraint belongs.

- `CONSTRAINT_NAME`

The name of the constraint.

- `TABLE_CATALOG`

The name of the catalog to which the table belongs. This value is always `def`.

- `TABLE_SCHEMA`

The name of the schema (database) to which the table belongs.

- `TABLE_NAME`

The name of the table that has the constraint.

- `COLUMN_NAME`

The name of the column that has the constraint.

If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.

- `ORDINAL_POSITION`

The column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.

- [POSITION\\_IN\\_UNIQUE\\_CONSTRAINT](#)

`NULL` for unique and primary-key constraints. For foreign-key constraints, this column is the ordinal position in key of the table that is being referenced.

- [REFERENCED\\_TABLE\\_SCHEMA](#)

The name of the schema (database) referenced by the constraint.

- [REFERENCED\\_TABLE\\_NAME](#)

The name of the table referenced by the constraint.

- [REFERENCED\\_COLUMN\\_NAME](#)

The name of the column referenced by the constraint.

Suppose that there are two tables name `t1` and `t3` that have the following definitions:

```
CREATE TABLE t1
(
 s1 INT,
 s2 INT,
 s3 INT,
 PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
 s1 INT,
 s2 INT,
 s3 INT,
 KEY(s1),
 CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME = 'PRIMARY', TABLE_NAME = 't1', COLUMN_NAME = 's3', ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = NULL`.
- One row with `CONSTRAINT_NAME = 'CO', TABLE_NAME = 't3', COLUMN_NAME = 's2', ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = 1`.

### 24.3.13 The INFORMATION\_SCHEMA ndb\_transid\_mysql\_connection\_map Table

The `ndb_transid_mysql_connection_map` table provides a mapping between `NDB` transactions, `NDB` transaction coordinators, and MySQL Servers attached to an NDB Cluster as API nodes. This information is used when populating the `server_operations` and `server_transactions` tables of the `ndbinfo` NDB Cluster information database.

The `ndb_transid_mysql_connection_map` table has these columns:

- [mysql\\_connection\\_id](#)

The MySQL server connection ID.

- [node\\_id](#)

The transaction coordinator node ID.

- [ndb\\_transid](#)

The `NDB` transaction ID.

## Notes

The `mysql_connection_id` value is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`.

There are no `SHOW` statements associated with this table.

This is a nonstandard table, specific to NDB Cluster. It is implemented as an `INFORMATION_SCHEMA` plugin; you can verify that it is supported by checking the output of `SHOW PLUGINS`. If `ndb_transid_mysql_connection_map` support is enabled, the output from this statement includes a plugin having this name, of type `INFORMATION SCHEMA`, and having status `ACTIVE`, as shown here (using emphasized text):

| Name                                    | Status        | Type                      | Library | License |
|-----------------------------------------|---------------|---------------------------|---------|---------|
| binlog                                  | ACTIVE        | STORAGE ENGINE            | NULL    | GPL     |
| mysql_native_password                   | ACTIVE        | AUTHENTICATION            | NULL    | GPL     |
| CSV                                     | ACTIVE        | STORAGE ENGINE            | NULL    | GPL     |
| MEMORY                                  | ACTIVE        | STORAGE ENGINE            | NULL    | GPL     |
| MRG_MYISAM                              | ACTIVE        | STORAGE ENGINE            | NULL    | GPL     |
| MyISAM                                  | ACTIVE        | STORAGE ENGINE            | NULL    | GPL     |
| PERFORMANCE_SCHEMA                      | ACTIVE        | STORAGE ENGINE            | NULL    | GPL     |
| BLACKHOLE                               | ACTIVE        | STORAGE ENGINE            | NULL    | GPL     |
| ARCHIVE                                 | ACTIVE        | STORAGE ENGINE            | NULL    | GPL     |
| ndbcluster                              | ACTIVE        | STORAGE ENGINE            | NULL    | GPL     |
| ndbinfo                                 | ACTIVE        | STORAGE ENGINE            | NULL    | GPL     |
| <i>ndb_transid_mysql_connection_map</i> | <i>ACTIVE</i> | <i>INFORMATION SCHEMA</i> | NULL    | GPL     |
| InnoDB                                  | ACTIVE        | STORAGE ENGINE            | NULL    | GPL     |
| INNODB_TRX                              | ACTIVE        | INFORMATION SCHEMA        | NULL    | GPL     |
| INNODB_LOCKS                            | ACTIVE        | INFORMATION SCHEMA        | NULL    | GPL     |
| INNODB_LOCK_WAITS                       | ACTIVE        | INFORMATION SCHEMA        | NULL    | GPL     |
| INNODB_CMP                              | ACTIVE        | INFORMATION SCHEMA        | NULL    | GPL     |
| INNODB_CMP_RESET                        | ACTIVE        | INFORMATION SCHEMA        | NULL    | GPL     |
| INNODB_CPMEM                            | ACTIVE        | INFORMATION SCHEMA        | NULL    | GPL     |
| INNODB_CPMEM_RESET                      | ACTIVE        | INFORMATION SCHEMA        | NULL    | GPL     |
| partition                               | ACTIVE        | STORAGE ENGINE            | NULL    | GPL     |

22 rows in set (0.00 sec)

The plugin is enabled by default. You can disable it (or force the server not to run unless the plugin starts) by starting the server with the `--ndb-transid-mysql-connection-map` option. If the plugin is disabled, the status is shown by `SHOW PLUGINS` as `DISABLED`. The plugin cannot be enabled or disabled at runtime.

Although the names of this table and its columns are displayed using lowercase, you can use uppercase or lowercase when referring to them in SQL statements.

For this table to be created, the MySQL Server must be a binary supplied with the NDB Cluster distribution, or one built from the NDB Cluster sources with `NDB` storage engine support enabled. It is not available in the standard MySQL 5.7 Server.

### 24.3.14 The INFORMATION\_SCHEMA OPTIMIZER\_TRACE Table

The `OPTIMIZER_TRACE` table provides information produced by the optimizer tracing capability for traced statements. To enable tracking, use the `optimizer_trace` system variable. For details, see [MySQL Internals: Tracing the Optimizer](#).

The `OPTIMIZER_TRACE` table has these columns:

- `QUERY`

The text of the traced statement.

- `TRACE`

The trace, in JSON format.

- **MISSING\_BYTES\_BEYOND\_MAX\_MEM\_SIZE**

Each remembered trace is a string that is extended as optimization progresses and appends data to it. The `optimizer_trace_max_mem_size` variable sets a limit on the total amount of memory used by all currently remembered traces. If this limit is reached, the current trace is not extended (and thus is incomplete), and the `MISSING_BYTES_BEYOND_MAX_MEM_SIZE` column shows the number of bytes missing from the trace.

- **INSUFFICIENT\_PRIVILEGES**

If a traced query uses views or stored routines that have `SQL SECURITY` with a value of `DEFINER`, it may be that a user other than the definer is denied from seeing the trace of the query. In that case, the trace is shown as empty and `INSUFFICIENT_PRIVILEGES` has a value of 1. Otherwise, the value is 0.

#### 24.3.15 The INFORMATION\_SCHEMA PARAMETERS Table

The `PARAMETERS` table provides information about parameters for stored routines (stored procedures and stored functions), and about return values for stored functions. The `PARAMETERS` table does not include built-in SQL functions or user-defined functions (UDFs). Parameter information is similar to the contents of the `param_list` column in the `mysql.proc` table.

The `PARAMETERS` table has these columns:

- **SPECIFIC\_CATALOG**

The name of the catalog to which the routine containing the parameter belongs. This value is always `def`.

- **SPECIFIC\_SCHEMA**

The name of the schema (database) to which the routine containing the parameter belongs.

- **SPECIFIC\_NAME**

The name of the routine containing the parameter.

- **ORDINAL\_POSITION**

For successive parameters of a stored procedure or function, the `ORDINAL_POSITION` values are 1, 2, 3, and so forth. For a stored function, there is also a row that applies to the function return value (as described by the `RETURNS` clause). The return value is not a true parameter, so the row that describes it has these unique characteristics:

- The `ORDINAL_POSITION` value is 0.
- The `PARAMETER_NAME` and `PARAMETER_MODE` values are `NULL` because the return value has no name and the mode does not apply.
- **PARAMETER\_MODE**

The mode of the parameter. This value is one of `IN`, `OUT`, or `INOUT`. For a stored function return value, this value is `NULL`.

- **PARAMETER\_NAME**

The name of the parameter. For a stored function return value, this value is `NULL`.

- **DATA\_TYPE**

The parameter data type.

The `DATA_TYPE` value is the type name only with no other information. The `DTD_IDENTIFIER` value contains the type name and possibly other information such as the precision or length.

- `CHARACTER_MAXIMUM_LENGTH`

For string parameters, the maximum length in characters.

- `CHARACTER_OCTET_LENGTH`

For string parameters, the maximum length in bytes.

- `NUMERIC_PRECISION`

For numeric parameters, the numeric precision.

- `NUMERIC_SCALE`

For numeric parameters, the numeric scale.

- `DATETIME_PRECISION`

For temporal parameters, the fractional seconds precision.

- `CHARACTER_SET_NAME`

For character string parameters, the character set name.

- `COLLATION_NAME`

For character string parameters, the collation name.

- `DTD_IDENTIFIER`

The parameter data type.

The `DATA_TYPE` value is the type name only with no other information. The `DTD_IDENTIFIER` value contains the type name and possibly other information such as the precision or length.

- `ROUTINE_TYPE`

`PROCEDURE` for stored procedures, `FUNCTION` for stored functions.

#### 24.3.16 The INFORMATION\_SCHEMA PARTITIONS Table

The `PARTITIONS` table provides information about table partitions. Each row in this table corresponds to an individual partition or subpartition of a partitioned table. For more information about partitioning tables, see [Chapter 22, Partitioning](#).

The `PARTITIONS` table has these columns:

- `TABLE_CATALOG`

The name of the catalog to which the table belongs. This value is always `def`.

- `TABLE_SCHEMA`

The name of the schema (database) to which the table belongs.

- `TABLE_NAME`

The name of the table containing the partition.

- **PARTITION\_NAME**

The name of the partition.

- **SUBPARTITION\_NAME**

If the **PARTITIONS** table row represents a subpartition, the name of subpartition; otherwise **NULL**.

- **PARTITION\_ORDINAL\_POSITION**

All partitions are indexed in the same order as they are defined, with **1** being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown is this column reflects the current order, taking into account any indexing changes.

- **SUBPARTITION\_ORDINAL\_POSITION**

Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.

- **PARTITION\_METHOD**

One of the values **RANGE**, **LIST**, **HASH**, **LINEAR HASH**, **KEY**, or **LINEAR KEY**; that is, one of the available partitioning types as discussed in [Section 22.2, “Partitioning Types”](#).

- **SUBPARTITION\_METHOD**

One of the values **HASH**, **LINEAR HASH**, **KEY**, or **LINEAR KEY**; that is, one of the available subpartitioning types as discussed in [Section 22.2.6, “Subpartitioning”](#).

- **PARTITION\_EXPRESSION**

The expression for the partitioning function used in the **CREATE TABLE** or **ALTER TABLE** statement that created the table's current partitioning scheme.

For example, consider a partitioned table created in the **test** database using this statement:

```
CREATE TABLE tp (
 c1 INT,
 c2 INT,
 c3 VARCHAR(25)
)
PARTITION BY HASH(c1 + c2)
PARTITIONS 4;
```

The **PARTITION\_EXPRESSION** column in a **PARTITIONS** table row for a partition from this table displays **c1 + c2**, as shown here:

```
mysql> SELECT DISTINCT PARTITION_EXPRESSION
 FROM INFORMATION_SCHEMA.PARTITIONS
 WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
+-----+
| PARTITION_EXPRESSION |
+-----+
| c1 + c2 |
+-----+
```

- **SUBPARTITION\_EXPRESSION**

This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as **PARTITION\_EXPRESSION** does for the partitioning expression used to define a table's partitioning.

If the table has no subpartitions, this column is **NULL**.

- **PARTITION\_DESCRIPTION**

This column is used for RANGE and LIST partitions. For a [RANGE](#) partition, it contains the value set in the partition's [VALUES LESS THAN](#) clause, which can be either an integer or [MAXVALUE](#). For a [LIST](#) partition, this column contains the values defined in the partition's [VALUES IN](#) clause, which is a list of comma-separated integer values.

For partitions whose [PARTITION\\_METHOD](#) is other than [RANGE](#) or [LIST](#), this column is always [NULL](#).

- [TABLE\\_ROWS](#)

The number of table rows in the partition.

For partitioned [InnoDB](#) tables, the row count given in the [TABLE\\_ROWS](#) column is only an estimated value used in SQL optimization, and may not always be exact.

For [NDB](#) tables, you can also obtain this information using the [ndb\\_desc](#) utility.

- [AVG\\_ROW\\_LENGTH](#)

The average length of the rows stored in this partition or subpartition, in bytes. This is the same as [DATA\\_LENGTH](#) divided by [TABLE\\_ROWS](#).

For [NDB](#) tables, you can also obtain this information using the [ndb\\_desc](#) utility.

- [DATA\\_LENGTH](#)

The total length of all rows stored in this partition or subpartition, in bytes; that is, the total number of bytes stored in the partition or subpartition.

For [NDB](#) tables, you can also obtain this information using the [ndb\\_desc](#) utility.

- [MAX\\_DATA\\_LENGTH](#)

The maximum number of bytes that can be stored in this partition or subpartition.

For [NDB](#) tables, you can also obtain this information using the [ndb\\_desc](#) utility.

- [INDEX\\_LENGTH](#)

The length of the index file for this partition or subpartition, in bytes.

For partitions of [NDB](#) tables, whether the tables use implicit or explicit partitioning, the [INDEX\\_LENGTH](#) column value is always 0. However, you can obtain equivalent information using the [ndb\\_desc](#) utility.

- [DATA\\_FREE](#)

The number of bytes allocated to the partition or subpartition but not used.

For [NDB](#) tables, you can also obtain this information using the [ndb\\_desc](#) utility.

- [CREATE\\_TIME](#)

The time that the partition or subpartition was created.

- [UPDATE\\_TIME](#)

The time that the partition or subpartition was last modified.

- [CHECK\\_TIME](#)

The last time that the table to which this partition or subpartition belongs was checked.

For partitioned [InnoDB](#) tables, the value is always [NULL](#).

- [CHECKSUM](#)

The checksum value, if any; otherwise [NULL](#).

- [PARTITION\\_COMMENT](#)

The text of the comment, if the partition has one. If not, this value is empty.

The maximum length for a partition comment is defined as 1024 characters, and the display width of the [PARTITION\\_COMMENT](#) column is also 1024, characters to match this limit.

- [NODEGROUP](#)

This is the nodegroup to which the partition belongs. This is relevant only to NDB Cluster tables; otherwise, the value is always [0](#).

- [TABLESPACE\\_NAME](#)

The name of the tablespace to which the partition belongs. The value is always [DEFAULT](#), unless the table uses the [NDB](#) storage engine (see the *Notes* at the end of this section).

## Notes

- [PARTITIONS](#) is a nonstandard [INFORMATION\\_SCHEMA](#) table.

- A table using any storage engine other than [NDB](#) and which is not partitioned has one row in the [PARTITIONS](#) table. However, the values of the [PARTITION\\_NAME](#), [SUBPARTITION\\_NAME](#), [PARTITION\\_ORDINAL\\_POSITION](#), [SUBPARTITION\\_ORDINAL\\_POSITION](#), [PARTITION\\_METHOD](#), [SUBPARTITION\\_METHOD](#), [PARTITION\\_EXPRESSION](#), [SUBPARTITION\\_EXPRESSION](#), and [PARTITION\\_DESCRIPTION](#) columns are all [NULL](#). Also, the [PARTITION\\_COMMENT](#) column in this case is blank.

- An [NDB](#) table which is not explicitly partitioned has one row in the [PARTITIONS](#) table for each data node in the NDB cluster. For each such row:

- The [SUBPARTITION\\_NAME](#), [SUBPARTITION\\_ORDINAL\\_POSITION](#), [SUBPARTITION\\_METHOD](#), [PARTITION\\_EXPRESSION](#), [SUBPARTITION\\_EXPRESSION](#), [CREATE\\_TIME](#), [UPDATE\\_TIME](#), [CHECK\\_TIME](#), [CHECKSUM](#), and [TABLESPACE\\_NAME](#) columns are all [NULL](#).
- The [PARTITION\\_METHOD](#) is always [KEY](#).
- The [NODEGROUP](#) column is [default](#).
- The [PARTITION\\_EXPRESSION](#) and [PARTITION\\_COMMENT](#) columns are empty.

## 24.3.17 The INFORMATION\_SCHEMA PLUGINS Table

The [PLUGINS](#) table provides information about server plugins.

The [PLUGINS](#) table has these columns:

- [PLUGIN\\_NAME](#)

The name used to refer to the plugin in statements such as [INSTALL PLUGIN](#) and [UNINSTALL PLUGIN](#).

- [PLUGIN\\_VERSION](#)

The version from the plugin's general type descriptor.

- [PLUGIN\\_STATUS](#)

The plugin status, one of [ACTIVE](#), [INACTIVE](#), [DISABLED](#), or [DELETED](#).

- **PLUGIN\_TYPE**  
The type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.
- **PLUGIN\_TYPE\_VERSION**  
The version from the plugin's type-specific descriptor.
- **PLUGIN\_LIBRARY**  
The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.
- **PLUGIN\_LIBRARY\_VERSION**  
The plugin API interface version.
- **PLUGIN\_AUTHOR**  
The plugin author.
- **PLUGIN\_DESCRIPTION**  
A short description of the plugin.
- **PLUGIN\_LICENSE**  
How the plugin is licensed (for example, `GPL`).
- **LOAD\_OPTION**  
How the plugin was loaded. The value is `OFF`, `ON`, `FORCE`, or `FORCE_PLUS_PERMANENT`. See [Section 5.5.1, “Installing and Uninstalling Plugins”](#).

## Notes

- `PLUGINS` is a nonstandard `INFORMATION_SCHEMA` table.
- For plugins installed with `INSTALL PLUGIN`, the `PLUGIN_NAME` and `PLUGIN_LIBRARY` values are also registered in the `mysql.plugin` table.
- For information about plugin data structures that form the basis of the information in the `PLUGINS` table, see [The MySQL Plugin API](#).

Plugin information is also available from the `SHOW PLUGINS` statement. See [Section 13.7.5.25, “SHOW PLUGINS Statement”](#). These statements are equivalent:

```
SELECT
 PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
 PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;

SHOW PLUGINS;
```

### 24.3.18 The INFORMATION\_SCHEMA PROCESSLIST Table

The MySQL process list indicates the operations currently being performed by the set of threads executing within the server. The `PROCESSLIST` table is one source of process information. For a comparison of this table with other sources, see [Sources of Process Information](#).

The `PROCESSLIST` table has these columns:

- [ID](#)

The connection identifier. This is the same value displayed in the `Id` column of the `SHOW PROCESSLIST` statement, displayed in the `PROCESSLIST_ID` column of the Performance Schema `threads` table, and returned by the `CONNECTION_ID()` function within the thread.

- [USER](#)

The MySQL user who issued the statement. A value of `system user` refers to a nonclient thread spawned by the server to handle tasks internally, for example, a delayed-row handler thread or an I/O or SQL thread used on replica hosts. For `system user`, there is no host specified in the `Host` column. `unauthenticated user` refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet occurred. `event_scheduler` refers to the thread that monitors scheduled events (see [Section 23.4, “Using the Event Scheduler”](#)).

- [HOST](#)

The host name of the client issuing the statement (except for `system user`, for which there is no host). The host name for TCP/IP connections is reported in `host_name:client_port` format to make it easier to determine which client is doing what.

- [DB](#)

The default database for the thread, or `NULL` if none has been selected.

- [COMMAND](#)

The type of command the thread is executing on behalf of the client, or `Sleep` if the session is idle. For descriptions of thread commands, see [Section 8.14, “Examining Server Thread \(Process\) Information”](#). The value of this column corresponds to the `COM_xxx` commands of the client/server protocol and `Com_xxx` status variables. See [Section 5.1.9, “Server Status Variables”](#).

- [TIME](#)

The time in seconds that the thread has been in its current state. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See [Section 16.2.3, “Replication Threads”](#).

- [STATE](#)

An action, event, or state that indicates what the thread is doing. For descriptions of `STATE` values, see [Section 8.14, “Examining Server Thread \(Process\) Information”](#).

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

- [INFO](#)

The statement the thread is executing, or `NULL` if it is executing no statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the `INFO` value shows the `SELECT` statement.

## Notes

- `PROCESSLIST` is a nonstandard `INFORMATION_SCHEMA` table.
- Like the output from the `SHOW PROCESSLIST` statement, the `PROCESSLIST` table provides information about all threads, even those belonging to other users, if you have the `PROCESS` privilege. Otherwise (without the `PROCESS` privilege), nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

- If an SQL statement refers to the `PROCESSLIST` table, MySQL populates the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
SHOW FULL PROCESSLIST
```

### 24.3.19 The INFORMATION\_SCHEMA PROFILING Table

The `PROFILING` table provides statement profiling information. Its contents correspond to the information produced by the `SHOW PROFILE` and `SHOW PROFILES` statements (see [Section 13.7.5.30, “SHOW PROFILE Statement”](#)). The table is empty unless the `profiling` session variable is set to 1.

#### Note

This table is deprecated; expect it to be removed in a future release of MySQL. Use the [Performance Schema](#) instead; see [Section 25.19.1, “Query Profiling Using Performance Schema”](#).

The `PROFILING` table has these columns:

- `QUERY_ID`

A numeric statement identifier.

- `SEQ`

A sequence number indicating the display order for rows with the same `QUERY_ID` value.

- `STATE`

The profiling state to which the row measurements apply.

- `DURATION`

How long statement execution remained in the given state, in seconds.

- `CPU_USER, CPU_SYSTEM`

User and system CPU use, in seconds.

- `CONTEXT_VOLUNTARY, CONTEXT_INVOLUNTARY`

How many voluntary and involuntary context switches occurred.

- `BLOCK_OPS_IN, BLOCK_OPS_OUT`

The number of block input and output operations.

- `MESSAGES_SENT, MESSAGES_RECEIVED`

The number of communication messages sent and received.

- `PAGEFAULTS_MAJOR, PAGEFAULTS_MINOR`

The number of major and minor page faults.

- `SWAPS`

How many swaps occurred.

- `SOURCE_FUNCTION`, `SOURCE_FILE`, and `SOURCE_LINE`

Information indicating where in the source code the profiled state executes.

## Notes

- `PROFILING` is a nonstandard `INFORMATION_SCHEMA` table.

Profiling information is also available from the `SHOW PROFILE` and `SHOW PROFILES` statements. See Section 13.7.5.30, “`SHOW PROFILE Statement`”. For example, the following queries are equivalent:

```
SHOW PROFILE FOR QUERY 2;

SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;
```

## 24.3.20 The INFORMATION\_SCHEMA REFERENTIAL\_CONSTRAINTS Table

The `REFERENTIAL_CONSTRAINTS` table provides information about foreign keys.

The `REFERENTIAL_CONSTRAINTS` table has these columns:

- `CONSTRAINT_CATALOG`

The name of the catalog to which the constraint belongs. This value is always `def`.

- `CONSTRAINT_SCHEMA`

The name of the schema (database) to which the constraint belongs.

- `CONSTRAINT_NAME`

The name of the constraint.

- `UNIQUE_CONSTRAINT_CATALOG`

The name of the catalog containing the unique constraint that the constraint references. This value is always `def`.

- `UNIQUE_CONSTRAINT_SCHEMA`

The name of the schema (database) containing the unique constraint that the constraint references.

- `UNIQUE_CONSTRAINT_NAME`

The name of the unique constraint that the constraint references.

- `MATCH_OPTION`

The value of the constraint `MATCH` attribute. The only valid value at this time is `NONE`.

- `UPDATE_RULE`

The value of the constraint `ON UPDATE` attribute. The possible values are `CASCADE`, `SET NULL`, `SET DEFAULT`, `RESTRICT`, `NO ACTION`.

- `DELETE_RULE`

The value of the constraint `ON DELETE` attribute. The possible values are `CASCADE`, `SET NULL`, `SET DEFAULT`, `RESTRICT`, `NO ACTION`.

- `TABLE_NAME`

The name of the table. This value is the same as in the `TABLE_CONSTRAINTS` table.

- [REFERENCED\\_TABLE\\_NAME](#)

The name of the table referenced by the constraint.

### 24.3.21 The INFORMATION\_SCHEMA ROUTINES Table

The [ROUTINES](#) table provides information about stored routines (stored procedures and stored functions). The [ROUTINES](#) table does not include built-in SQL functions or user-defined functions (UDFs).

The column named “`mysql.proc` Name” indicates the `mysql.proc` table column that corresponds to the [INFORMATION\\_SCHEMA ROUTINES](#) table column, if any.

The [ROUTINES](#) table has these columns:

- [SPECIFIC\\_NAME](#)

The name of the routine.

- [ROUTINE\\_CATALOG](#)

The name of the catalog to which the routine belongs. This value is always `def`.

- [ROUTINE\\_SCHEMA](#)

The name of the schema (database) to which the routine belongs.

- [ROUTINE\\_NAME](#)

The name of the routine.

- [ROUTINE\\_TYPE](#)

`PROCEDURE` for stored procedures, `FUNCTION` for stored functions.

- [DATA\\_TYPE](#)

If the routine is a stored function, the return value data type. If the routine is a stored procedure, this value is empty.

The [DATA\\_TYPE](#) value is the type name only with no other information. The [DTD\\_IDENTIFIER](#) value contains the type name and possibly other information such as the precision or length.

- [CHARACTER\\_MAXIMUM\\_LENGTH](#)

For stored function string return values, the maximum length in characters. If the routine is a stored procedure, this value is `NULL`.

- [CHARACTER\\_OCTET\\_LENGTH](#)

For stored function string return values, the maximum length in bytes. If the routine is a stored procedure, this value is `NULL`.

- [NUMERIC\\_PRECISION](#)

For stored function numeric return values, the numeric precision. If the routine is a stored procedure, this value is `NULL`.

- [NUMERIC\\_SCALE](#)

For stored function numeric return values, the numeric scale. If the routine is a stored procedure, this value is `NULL`.

- [DATETIME\\_PRECISION](#)

For stored function temporal return values, the fractional seconds precision. If the routine is a stored procedure, this value is `NULL`.

- `CHARACTER_SET_NAME`

For stored function character string return values, the character set name. If the routine is a stored procedure, this value is `NULL`.

- `COLLATION_NAME`

For stored function character string return values, the collation name. If the routine is a stored procedure, this value is `NULL`.

- `DTD_IDENTIFIER`

If the routine is a stored function, the return value data type. If the routine is a stored procedure, this value is empty.

The `DATA_TYPE` value is the type name only with no other information. The `DTD_IDENTIFIER` value contains the type name and possibly other information such as the precision or length.

- `ROUTINE_BODY`

The language used for the routine definition. This value is always `SQL`.

- `ROUTINE_DEFINITION`

The text of the SQL statement executed by the routine.

- `EXTERNAL_NAME`

This value is always `NULL`.

- `EXTERNAL_LANGUAGE`

The language of the stored routine. MySQL calculates `EXTERNAL_LANGUAGE` thus:

- If `mysql.proc.language='SQL'`, `EXTERNAL_LANGUAGE` is `NULL`

- Otherwise, `EXTERNAL_LANGUAGE` is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always `NULL`.

- `PARAMETER_STYLE`

This value is always `SQL`.

- `IS_DETERMINISTIC`

`YES` or `NO`, depending on whether the routine is defined with the `DETERMINISTIC` characteristic.

- `SQL_DATA_ACCESS`

The data access characteristic for the routine. The value is one of `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, or `MODIFIES SQL DATA`.

- `SQL_PATH`

This value is always `NULL`.

- `SECURITY_TYPE`

The routine `SQL SECURITY` characteristic. The value is one of `DEFINER` or `INVOKER`.

- `CREATED`

The date and time when the routine was created. This is a `TIMESTAMP` value.

- `LAST_ALTERED`

The date and time when the routine was last modified. This is a `TIMESTAMP` value. If the routine has not been modified since its creation, this value is the same as the `CREATED` value.

- `SQL_MODE`

The SQL mode in effect when the routine was created or altered, and under which the routine executes. For the permitted values, see [Section 5.1.10, “Server SQL Modes”](#).

- `ROUTINE_COMMENT`

The text of the comment, if the routine has one. If not, this value is empty.

- `DEFINER`

The account named in the `DEFINER` clause (often the user who created the routine), in `'user_name'@'host_name'` format.

- `CHARACTER_SET_CLIENT`

The session value of the `character_set_client` system variable when the routine was created.

- `COLLATION_CONNECTION`

The session value of the `collation_connection` system variable when the routine was created.

- `DATABASE_COLLATION`

The collation of the database with which the routine is associated.

## Notes

- To see information about a routine, you must be the user named in the routine `DEFINER` clause or have `SELECT` access to the `mysql.proc` table. If you do not have privileges for the routine itself, the value displayed for the `ROUTINE_DEFINITION` column is `NULL`.
- Information about stored function return values is also available in the `PARAMETERS` table. The return value row for a stored function can be identified as the row that has an `ORDINAL_POSITION` value of 0.

## 24.3.22 The INFORMATION\_SCHEMA SCHEMATA Table

A schema is a database, so the `SCHEMATA` table provides information about databases.

The `SCHEMATA` table has these columns:

- `CATALOG_NAME`

The name of the catalog to which the schema belongs. This value is always `def`.

- `SCHEMA_NAME`

The name of the schema.

- `DEFAULT_CHARACTER_SET_NAME`

The schema default character set.

- `DEFAULT_COLLATION_NAME`

The schema default collation.

- [SQL\\_PATH](#)

This value is always `NULL`.

Schema names are also available from the `SHOW DATABASES` statement. See [Section 13.7.5.14, “SHOW DATABASES Statement”](#). The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
 FROM INFORMATION_SCHEMA.SCHEMATA
 [WHERE SCHEMA_NAME LIKE 'wild']

SHOW DATABASES
 [LIKE 'wild']
```

You see only those databases for which you have some kind of privilege, unless you have the global `SHOW DATABASES` privilege.

### Caution

Because a global privilege is considered a privilege for all databases, *any* global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `INFORMATION_SCHEMA SCHEMATA` table.

## 24.3.23 The INFORMATION\_SCHEMA SCHEMA\_PRIVILEGES Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. It takes its values from the `mysql.db` system table.

The `SCHEMA_PRIVILEGES` table has these columns:

- [GRANTEE](#)

The name of the account to which the privilege is granted, in '`user_name`@`host_name`' format.

- [TABLE\\_CATALOG](#)

The name of the catalog to which the schema belongs. This value is always `def`.

- [TABLE\\_SCHEMA](#)

The name of the schema.

- [PRIVILEGE\\_TYPE](#)

The privilege granted. The value can be any privilege that can be granted at the schema level; see [Section 13.7.1.4, “GRANT Statement”](#). Each row lists a single privilege, so there is one row per schema privilege held by the grantee.

- [IS\\_GRANTABLE](#)

`YES` if the user has the `GRANT OPTION` privilege, `NO` otherwise. The output does not list `GRANT OPTION` as a separate row with `PRIVILEGE_TYPE='GRANT OPTION'`.

## Notes

- `SCHEMA_PRIVILEGES` is a nonstandard `INFORMATION_SCHEMA` table.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.SCHEMA_PRIVILEGES

SHOW GRANTS ...
```

## 24.3.24 The INFORMATION\_SCHEMA STATISTICS Table

The `STATISTICS` table provides information about table indexes.

The `STATISTICS` table has these columns:

- `TABLE_CATALOG`

The name of the catalog to which the table containing the index belongs. This value is always `def`.

- `TABLE_SCHEMA`

The name of the schema (database) to which the table containing the index belongs.

- `TABLE_NAME`

The name of the table containing the index.

- `NON_UNIQUE`

0 if the index cannot contain duplicates, 1 if it can.

- `INDEX_SCHEMA`

The name of the schema (database) to which the index belongs.

- `INDEX_NAME`

The name of the index. If the index is the primary key, the name is always `PRIMARY`.

- `SEQ_IN_INDEX`

The column sequence number in the index, starting with 1.

- `COLUMN_NAME`

The column name. See also the description for the `EXPRESSION` column.

- `COLLATION`

How the column is sorted in the index. This can have values `A` (ascending), `D` (descending), or `NULL` (not sorted).

- `CARDINALITY`

An estimate of the number of unique values in the index. To update this number, run `ANALYZE TABLE` or (for MyISAM tables) `myisamchk -a`.

`CARDINALITY` is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- `SUB_PART`

The index prefix. That is, the number of indexed characters if the column is only partly indexed, `NULL` if the entire column is indexed.

#### Note

Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

For additional information about index prefixes, see [Section 8.3.4, “Column Indexes”](#), and [Section 13.1.14, “CREATE INDEX Statement”](#).

- [PACKED](#)

Indicates how the key is packed. [NULL](#) if it is not.

- [NULLABLE](#)

Contains [YES](#) if the column may contain [NULL](#) values and [''](#) if not.

- [INDEX\\_TYPE](#)

The index method used ([BTREE](#), [FULLTEXT](#), [HASH](#), [RTREE](#)).

- [COMMENT](#)

Information about the index not described in its own column, such as [disabled](#) if the index is disabled.

- [INDEX\\_COMMENT](#)

Any comment provided for the index with a [COMMENT](#) attribute when the index was created.

## Notes

- There is no standard [INFORMATION\\_SCHEMA](#) table for indexes. The MySQL column list is similar to what SQL Server 2000 returns for [sp\\_statistics](#), except that [QUALIFIER](#) and [OWNER](#) are replaced with [CATALOG](#) and [SCHEMA](#), respectively.

Information about table indexes is also available from the [SHOW INDEX](#) statement. See [Section 13.7.5.22, “SHOW INDEX Statement”](#). The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
 WHERE table_name = 'tbl_name'
 AND table_schema = 'db_name'

SHOW INDEX
 FROM tbl_name
 FROM db_name
```

### 24.3.25 The INFORMATION\_SCHEMA TABLES Table

The [TABLES](#) table provides information about tables in databases.

The [TABLES](#) table has these columns:

- [TABLE\\_CATALOG](#)

The name of the catalog to which the table belongs. This value is always [def](#).

- [TABLE\\_SCHEMA](#)

The name of the schema (database) to which the table belongs.

- [TABLE\\_NAME](#)

The name of the table.

- [TABLE\\_TYPE](#)

[BASE\\_TABLE](#) for a table, [VIEW](#) for a view, or [SYSTEM\\_VIEW](#) for an [INFORMATION\\_SCHEMA](#) table.

The [TABLES](#) table does not list [TEMPORARY](#) tables.

- [ENGINE](#)

The storage engine for the table. See [Chapter 14, “The InnoDB Storage Engine”](#), and [Chapter 15, “Alternative Storage Engines”](#).

For partitioned tables, `ENGINE` shows the name of the storage engine used by all partitions.

- `VERSION`

The version number of the table's `.frm` file.

- `ROW_FORMAT`

The row-storage format (`Fixed`, `Dynamic`, `Compressed`, `Redundant`, `Compact`). For `MyISAM` tables, `Dynamic` corresponds to what `myisamchk -dvv` reports as `Packed`. `InnoDB` table format is either `Redundant` or `Compact` when using the `Antelope` file format, or `Compressed` or `Dynamic` when using the `Barracuda` file format.

- `TABLE_ROWS`

The number of rows. Some storage engines, such as `MyISAM`, store the exact count. For other storage engines, such as `InnoDB`, this value is an approximation, and may vary from the actual value by as much as 40% to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.

`TABLE_ROWS` is `NULL` for `INFORMATION_SCHEMA` tables.

For `InnoDB` tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the `InnoDB` table is partitioned.)

- `AVG_ROW_LENGTH`

The average row length.

Refer to the notes at the end of this section for related information.

- `DATA_LENGTH`

For `MyISAM`, `DATA_LENGTH` is the length of the data file, in bytes.

For `InnoDB`, `DATA_LENGTH` is the approximate amount of space allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the `InnoDB` page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- `MAX_DATA_LENGTH`

For `MyISAM`, `MAX_DATA_LENGTH` is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

Unused for `InnoDB`.

Refer to the notes at the end of this section for information regarding other storage engines.

- `INDEX_LENGTH`

For `MyISAM`, `INDEX_LENGTH` is the length of the index file, in bytes.

For `InnoDB`, `INDEX_LENGTH` is the approximate amount of space allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the `InnoDB` page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- `DATA_FREE`

The number of allocated but unused bytes.

[InnoDB](#) tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

For NDB Cluster, [DATA\\_FREE](#) shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the [DATA\\_LENGTH](#) column.)

For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the [INFORMATION\\_SCHEMA PARTITIONS](#) table, as shown in this example:

```
SELECT SUM(DATA_FREE)
 FROM INFORMATION_SCHEMA.PARTITIONS
 WHERE TABLE_SCHEMA = 'mydb'
 AND TABLE_NAME = 'mytable';
```

For more information, see [Section 24.3.16, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#).

- [AUTO\\_INCREMENT](#)

The next [AUTO\\_INCREMENT](#) value.

- [CREATE\\_TIME](#)

When the table was created.

- [UPDATE\\_TIME](#)

When the data file was last updated. For some storage engines, this value is [NULL](#). For example, [InnoDB](#) stores multiple tables in its [system tablespace](#) and the data file timestamp does not apply. Even with [file-per-table](#) mode with each [InnoDB](#) table in a separate [.ibd](#) file, [change buffering](#) can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For [MyISAM](#), the data file timestamp is used; however, on Windows the timestamp is not updated by updates, so the value is inaccurate.

[UPDATE\\_TIME](#) displays a timestamp value for the last [UPDATE](#), [INSERT](#), or [DELETE](#) performed on [InnoDB](#) tables that are not partitioned. For MVCC, the timestamp value reflects the [COMMIT](#) time, which is considered the last update time. Timestamps are not persisted when the server is restarted or when the table is evicted from the [InnoDB](#) data dictionary cache.

The [UPDATE\\_TIME](#) column also shows this information for partitioned [InnoDB](#) tables.

- [CHECK\\_TIME](#)

When the table was last checked. Not all storage engines update this time, in which case, the value is always [NULL](#).

For partitioned [InnoDB](#) tables, [CHECK\\_TIME](#) is always [NULL](#).

- [TABLE\\_COLLATION](#)

The table default collation. The output does not explicitly list the table default character set, but the collation name begins with the character set name.

- [CHECKSUM](#)

The live checksum value, if any.

- [CREATE\\_OPTIONS](#)

Extra options used with `CREATE TABLE`.

`CREATE_OPTIONS` shows `partitioned` if the table is partitioned.

`CREATE_OPTIONS` shows the `ENCRYPTION` clause specified for tables created in file-per-table tablespaces.

When creating a table with `strict mode` disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the `ROW_FORMAT` column. `CREATE_OPTIONS` shows the row format that was specified in the `CREATE TABLE` statement.

When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. The `CREATE_OPTIONS` column may show retained options.

- `TABLE_COMMENT`

The comment used when creating the table (or information as to why MySQL could not access the table information).

## Notes

- For `NDB` tables, the output of this statement shows appropriate values for the `AVG_ROW_LENGTH` and `DATA_LENGTH` columns, with the exception that `BLOB` columns are not taken into account.
- For `NDB` tables, `DATA_LENGTH` includes data stored in main memory only; the `MAX_DATA_LENGTH` and `DATA_FREE` columns apply to Disk Data.
- For NDB Cluster Disk Data tables, `MAX_DATA_LENGTH` shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the `DATA_LENGTH` column.)
- For `MEMORY` tables, the `DATA_LENGTH`, `MAX_DATA_LENGTH`, and `INDEX_LENGTH` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.
- For views, all `TABLES` columns are `NULL` except that `TABLE_NAME` indicates the view name and `TABLE_COMMENT` says `VIEW`.

Table information is also available from the `SHOW TABLE STATUS` and `SHOW TABLES` statements. See [Section 13.7.5.36, “SHOW TABLE STATUS Statement”](#), and [Section 13.7.5.37, “SHOW TABLES Statement”](#). The following statements are equivalent:

```
SELECT
 TABLE_NAME, ENGINE, VERSION, ROW_FORMAT, TABLE_ROWS, AVG_ROW_LENGTH,
 DATA_LENGTH, MAX_DATA_LENGTH, INDEX_LENGTH, DATA_FREE, AUTO_INCREMENT,
 CREATE_TIME, UPDATE_TIME, CHECK_TIME, TABLE_COLLATION, CHECKSUM,
 CREATE_OPTIONS, TABLE_COMMENT
FROM INFORMATION_SCHEMA.TABLES
WHERE table_schema = 'db_name'
[AND table_name LIKE 'wild']

SHOW TABLE STATUS
 FROM db_name
 [LIKE 'wild']
```

The following statements are equivalent:

```
SELECT
 TABLE_NAME, TABLE_TYPE
FROM INFORMATION_SCHEMA.TABLES
```

```
WHERE table_schema = 'db_name'
[AND table_name LIKE 'wild']

SHOW FULL TABLES
FROM db_name
[LIKE 'wild']
```

## 24.3.26 The INFORMATION\_SCHEMA TABLESPACES Table

This table is unused. Other [INFORMATION\\_SCHEMA](#) tables may provide related information:

- For [NDB](#), the [INFORMATION\\_SCHEMA FILES](#) table provides tablespace-related information.
- For [InnoDB](#), the [INFORMATION\\_SCHEMA INNODB\\_SYS\\_TABLESPACES](#) and [INNODB\\_SYS\\_DATAFILES](#) tables provide tablespace metadata.

## 24.3.27 The INFORMATION\_SCHEMA TABLE\_CONSTRAINTS Table

The [TABLE\\_CONSTRAINTS](#) table describes which tables have constraints.

The [TABLE\\_CONSTRAINTS](#) table has these columns:

- [CONSTRAINT\\_CATALOG](#)

The name of the catalog to which the constraint belongs. This value is always [def](#).

- [CONSTRAINT\\_SCHEMA](#)

The name of the schema (database) to which the constraint belongs.

- [TABLE\\_SCHEMA](#)

The name of the schema (database) to which the table belongs.

- [TABLE\\_NAME](#)

The name of the table.

- The [CONSTRAINT\\_TYPE](#)

The type of constraint. The value can be [UNIQUE](#), [PRIMARY KEY](#), [FOREIGN KEY](#), or [CHECK](#). This is a [CHAR](#) (not [ENUM](#)) column. The [CHECK](#) value is not available until MySQL supports [CHECK](#).

The [UNIQUE](#) and [PRIMARY KEY](#) information is about the same as what you get from the [Key\\_name](#) column in the output from [SHOW INDEX](#) when the [Non\\_unique](#) column is [0](#).

## 24.3.28 The INFORMATION\_SCHEMA TABLE\_PRIVILEGES Table

The [TABLE\\_PRIVILEGES](#) table provides information about table privileges. It takes its values from the [mysql.tables\\_priv](#) system table.

The [TABLE\\_PRIVILEGES](#) table has these columns:

- [GRANTEE](#)

The name of the account to which the privilege is granted, in '[user\\_name](#)'@'[host\\_name](#)' format.

- [TABLE\\_CATALOG](#)

The name of the catalog to which the table belongs. This value is always [def](#).

- [TABLE\\_SCHEMA](#)

The name of the schema (database) to which the table belongs.

- `TABLE_NAME`

The name of the table.

- `PRIVILEGE_TYPE`

The privilege granted. The value can be any privilege that can be granted at the table level; see [Section 13.7.1.4, “GRANT Statement”](#). Each row lists a single privilege, so there is one row per table privilege held by the grantee.

- `IS_GRANTABLE`

`YES` if the user has the `GRANT OPTION` privilege, `NO` otherwise. The output does not list `GRANT OPTION` as a separate row with `PRIVILEGE_TYPE='GRANT OPTION'`.

## Notes

- `TABLE_PRIVILEGES` is a nonstandard `INFORMATION_SCHEMA` table.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

## 24.3.29 The INFORMATION\_SCHEMA TRIGGERS Table

The `TRIGGERS` table provides information about triggers. To see information about a table's triggers, you must have the `TRIGGER` privilege for the table.

The `TRIGGERS` table has these columns:

- `TRIGGER_CATALOG`

The name of the catalog to which the trigger belongs. This value is always `def`.

- `TRIGGER_SCHEMA`

The name of the schema (database) to which the trigger belongs.

- `TRIGGER_NAME`

The name of the trigger.

- `EVENT_MANIPULATION`

The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is `INSERT` (a row was inserted), `DELETE` (a row was deleted), or `UPDATE` (a row was modified).

- `EVENT_OBJECT_CATALOG`, `EVENT_OBJECT_SCHEMA`, and `EVENT_OBJECT_TABLE`

As noted in [Section 23.3, “Using Triggers”](#), every trigger is associated with exactly one table. These columns indicate the catalog and schema (database) in which this table occurs, and the table name, respectively. The `EVENT_OBJECT_CATALOG` value is always `def`.

- `ACTION_ORDER`

The ordinal position of the trigger's action within the list of triggers on the same table with the same `EVENT_MANIPULATION` and `ACTION_TIMING` values.

- [ACTION\\_CONDITION](#)

This value is always `NULL`.

- [ACTION\\_STATEMENT](#)

The trigger body; that is, the statement executed when the trigger activates. This text uses UTF-8 encoding.

- [ACTION\\_ORIENTATION](#)

This value is always `ROW`.

- [ACTION\\_TIMING](#)

Whether the trigger activates before or after the triggering event. The value is `BEFORE` or `AFTER`.

- [ACTION\\_REFERENCE\\_OLD\\_TABLE](#)

This value is always `NULL`.

- [ACTION\\_REFERENCE\\_NEW\\_TABLE](#)

This value is always `NULL`.

- [ACTION\\_REFERENCE\\_OLD\\_ROW](#) and [ACTION\\_REFERENCE\\_NEW\\_ROW](#)

The old and new column identifiers, respectively. The `ACTION_REFERENCE_OLD_ROW` value is always `OLD` and the `ACTION_REFERENCE_NEW_ROW` value is always `NEW`.

- [CREATED](#)

The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers created in MySQL 5.7.2 or later, `NULL` for triggers created prior to 5.7.2.

- [SQL\\_MODE](#)

The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see [Section 5.1.10, “Server SQL Modes”](#).

- [DEFINER](#)

The account named in the `DEFINER` clause (often the user who created the trigger), in `'user_name'@'host_name'` format.

- [CHARACTER\\_SET\\_CLIENT](#)

The session value of the `character_set_client` system variable when the trigger was created.

- [COLLATION\\_CONNECTION](#)

The session value of the `collation_connection` system variable when the trigger was created.

- [DATABASE\\_COLLATION](#)

The collation of the database with which the trigger is associated.

## Example

The following example uses the `ins_sum` trigger defined in [Section 23.3, “Using Triggers”](#):

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS
```

```

WHERE TRIGGER_SCHEMA='test' AND TRIGGER_NAME='ins_sum'\G
***** 1. row *****
 TRIGGER_CATALOG: def
 TRIGGER_SCHEMA: test
 TRIGGER_NAME: ins_sum
 EVENT_MANIPULATION: INSERT
 EVENT_OBJECT_CATALOG: def
 EVENT_OBJECT_SCHEMA: test
 EVENT_OBJECT_TABLE: account
 ACTION_ORDER: 1
 ACTION_CONDITION: NULL
 ACTION_STATEMENT: SET @sum = @sum + NEW.amount
 ACTION_ORIENTATION: ROW
 ACTION_TIMING: BEFORE
ACTION_REFERENCE_OLD_TABLE: NULL
ACTION_REFERENCE_NEW_TABLE: NULL
 ACTION_REFERENCE_OLD_ROW: OLD
 ACTION_REFERENCE_NEW_ROW: NEW
 CREATED: 2018-08-08 10:10:12.61
 SQL_MODE: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
 NO_ZERO_IN_DATE,NO_ZERO_DATE,
 ERROR_FOR_DIVISION_BY_ZERO,
 NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION
 DEFINER: me@localhost
CHARACTER_SET_CLIENT: utf8
COLLATION_CONNECTION: utf8_general_ci
DATABASE_COLLATION: latin1_swedish_ci

```

Trigger information is also available from the `SHOW TRIGGERS` statement. See [Section 13.7.5.38, “SHOW TRIGGERS Statement”](#).

### 24.3.30 The INFORMATION\_SCHEMA USER\_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. It takes its values from the `mysql.user` system table.

The `USER_PRIVILEGES` table has these columns:

- `GRANTEE`

The name of the account to which the privilege is granted, in '`'user_name'@'host_name'`' format.

- `TABLE_CATALOG`

The name of the catalog. This value is always `def`.

- `PRIVILEGE_TYPE`

The privilege granted. The value can be any privilege that can be granted at the global level; see [Section 13.7.1.4, “GRANT Statement”](#). Each row lists a single privilege, so there is one row per global privilege held by the grantee.

- `IS_GRANTABLE`

`YES` if the user has the `GRANT OPTION` privilege, `NO` otherwise. The output does not list `GRANT OPTION` as a separate row with `PRIVILEGE_TYPE='GRANT OPTION'`.

### Notes

- `USER_PRIVILEGES` is a nonstandard `INFORMATION_SCHEMA` table.

The following statements are *not* equivalent:

```

SELECT ... FROM INFORMATION_SCHEMA.USER_PRIVILEGES
SHOW GRANTS ...

```

### 24.3.31 The INFORMATION\_SCHEMA VIEWS Table

The `VIEWS` table provides information about views in databases. You must have the `SHOW VIEW` privilege to access this table.

The `VIEWS` table has these columns:

- `TABLE_CATALOG`

The name of the catalog to which the view belongs. This value is always `def`.

- `TABLE_SCHEMA`

The name of the schema (database) to which the view belongs.

- `TABLE_NAME`

The name of the view.

- `VIEW_DEFINITION`

The `SELECT` statement that provides the definition of the view. This column has most of what you see in the `Create Table` column that `SHOW CREATE VIEW` produces. Skip the words before `SELECT` and skip the words `WITH CHECK OPTION`. Suppose that the original statement was:

```
CREATE VIEW v AS
 SELECT s2,s1 FROM t
 WHERE s1 > 5
 ORDER BY s1
 WITH CHECK OPTION;
```

Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- `CHECK_OPTION`

The value of the `CHECK_OPTION` attribute. The value is one of `NONE`, `CASCADE`, or `LOCAL`.

- `IS_UPDATABLE`

MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `VIEWS` table displays the status of this flag.

If a view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and are rejected. (Even if a view is updatable, it might not be possible to insert into it; for details, refer to [Section 23.5.3, “Updatable and Insertable Views”](#).)

The `IS_UPDATABLE` flag may be unreliable if a view depends on one or more other views, and one of these underlying views is updated. Regardless of the `IS_UPDATABLE` value, the server keeps track of the updatability of a view and correctly rejects data change operations to views that are not updatable. If the `IS_UPDATABLE` value for a view has become inaccurate due to changes to underlying views, the value can be updated by deleting and re-creating the view.

- `DEFINER`

The account of the user who created the view, in '`user_name`'@'`host_name`' format.

- `SECURITY_TYPE`

The view `SQL SECURITY` characteristic. The value is one of `DEFINER` or `INVOKER`.

- `CHARACTER_SET_CLIENT`

The session value of the `character_set_client` system variable when the view was created.

- `COLLATION_CONNECTION`

The session value of the `collation_connection` system variable when the view was created.

## Notes

MySQL permits different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
 WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+-----+
| VIEW_DEFINITION |
+-----+
| select concat('a','b') AS `coll` |
+-----+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` do not affect the results from the view. However, an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

## 24.4 INFORMATION\_SCHEMA InnoDB Tables

This section provides table definitions for `INFORMATION_SCHEMA` InnoDB tables. For related information and examples, see [Section 14.16, “InnoDB INFORMATION\\_SCHEMA Tables”](#).

`INFORMATION_SCHEMA` InnoDB tables can be used to monitor ongoing InnoDB activity, to detect inefficiencies before they turn into issues, or to troubleshoot performance and capacity issues. As your database becomes bigger and busier, running up against the limits of your hardware capacity, you monitor and tune these aspects to keep the database running smoothly.

### 24.4.1 INFORMATION\_SCHEMA InnoDB Table Reference

The following table summarizes `INFORMATION_SCHEMA` InnoDB tables. For greater detail, see the individual table descriptions.

**Table 24.3 INFORMATION\_SCHEMA InnoDB Tables**

| Name                                 | Description                                               | Deprecated |
|--------------------------------------|-----------------------------------------------------------|------------|
| <code>INNODB_BUFFER_PAGE</code>      | Pages in InnoDB buffer pool                               |            |
| <code>INNODB_BUFFER_PAGE_LIST</code> | LRU ordering of pages in InnoDB buffer pool               |            |
| <code>INNODB_BUFFER_POOL</code>      | InnoDB buffer pool statistics                             |            |
| <code>INNODB_CMP</code>              | Status for operations related to compressed InnoDB tables |            |

| Name                        | Description                                                                                 | Deprecated |
|-----------------------------|---------------------------------------------------------------------------------------------|------------|
| INNODB_CMP_PER_INDEX_STATUS | Status for operations related to compressed InnoDB tables and indexes                       |            |
| INNODB_CMP_PER_INDEX_RESET  | Status for operations related to compressed InnoDB tables and indexes                       |            |
| INNODB_CMP_RESET            | Status for operations related to compressed InnoDB tables                                   |            |
| INNODB_CMPMEM               | Status for compressed pages within InnoDB buffer pool                                       |            |
| INNODB_CMPMEM_RESET         | Status for compressed pages within InnoDB buffer pool                                       |            |
| INNODB_FT_BEING_DELETED     | Snapshot of INNODB_FT_DELETED table                                                         |            |
| INNODB_FT_CONFIG            | Metadata for InnoDB table FULLTEXT index and associated processing                          |            |
| INNODB_FT_DEFAULT_STOPWORD  | Default list of stopwords for InnoDB FULLTEXT indexes                                       |            |
| INNODB_FT_DELETED           | Rows deleted from InnoDB table FULLTEXT index                                               |            |
| INNODB_FT_INDEX_CACHE       | Token information for newly inserted rows in InnoDB FULLTEXT index                          |            |
| INNODB_FT_INDEX_TABLE       | Inverted index information for processing text searches against InnoDB table FULLTEXT index |            |
| INNODB_LOCK_WAITS           | InnoDB transaction lock-wait information                                                    | 5.7.14     |
| INNODB_LOCKS                | InnoDB transaction lock information                                                         | 5.7.14     |
| INNODB_METRICS              | InnoDB performance information                                                              |            |
| INNODB_SYS_COLUMNS          | Columns in each InnoDB table                                                                |            |
| INNODB_SYS_DATAFILE         | Data file path information for InnoDB file-per-table and general tablespaces                |            |
| INNODB_SYS_FIELDS           | Key columns of InnoDB indexes                                                               |            |
| INNODB_SYS_FOREIGN          | InnoDB foreign-key metadata                                                                 |            |
| INNODB_SYS_FOREIGN_COLS     | InnoDB foreign-key column status information                                                |            |
| INNODB_SYS_INDEXES          | InnoDB index metadata                                                                       |            |
| INNODB_SYS_TABLES           | InnoDB table metadata                                                                       |            |
| INNODB_SYS_TABLESPACES      | InnoDB file-per-table, general, and undo tablespace metadata                                |            |
| INNODB_SYS_TABLESTATISTICS  | InnoDB table low-level status information                                                   |            |
| INNODB_SYS_VIRTUAL          | InnoDB virtual generated column metadata                                                    |            |
| INNODB_TEMP_TABLE_INFO      | Information about active user-created InnoDB temporary tables                               |            |
| INNODB_TRX                  | Active InnoDB transaction information                                                       |            |

#### 24.4.2 The INFORMATION\_SCHEMA INNODB\_BUFFER\_PAGE Table

The `INNODB_BUFFER_PAGE` table provides information about each page in the InnoDB buffer pool.

For related usage information and examples, see [Section 14.16.5, “InnoDB INFORMATION\\_SCHEMA Buffer Pool Tables”](#).

##### Warning

Querying the `INNODB_BUFFER_PAGE` table can affect performance. Do not query this table on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

The `INNODB_BUFFER_PAGE` table has these columns:

- `POOL_ID`

The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- `BLOCK_ID`

The buffer pool block ID.

- `SPACE`

The tablespace ID; the same value as `INNODB_SYS_TABLES.SPACE`.

- `PAGE_NUMBER`

The page number.

- `PAGE_TYPE`

The page type. The following table shows the permitted values.

**Table 24.4 INNODB\_BUFFER\_PAGE.PAGE\_TYPE Values**

| Page Type                      | Description                |
|--------------------------------|----------------------------|
| <code>ALLOCATED</code>         | Freshly allocated page     |
| <code>BLOB</code>              | Uncompressed BLOB page     |
| <code>COMPRESSED_BLOB2</code>  | Subsequent comp BLOB page  |
| <code>COMPRESSED_BLOB</code>   | First compressed BLOB page |
| <code>EXTENT_DESCRIPTOR</code> | Extent descriptor page     |
| <code>FILE_SPACE_HEADER</code> | File space header          |
| <code>IBUF_BITMAP</code>       | Insert buffer bitmap       |
| <code>IBUF_FREE_LIST</code>    | Insert buffer free list    |
| <code>IBUF_INDEX</code>        | Insert buffer index        |
| <code>INDEX</code>             | B-tree node                |
| <code>INODE</code>             | Index node                 |
| <code>RTREE_INDEX</code>       | R-tree index               |
| <code>SYSTEM</code>            | System page                |
| <code>TRX_SYSTEM</code>        | Transaction system data    |
| <code>UNDO_LOG</code>          | Undo log page              |
| <code>UNKNOWN</code>           | Unknown                    |

- `FLUSH_TYPE`

The flush type.

- `FIX_COUNT`

The number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.

- `IS_HASHED`

Whether a hash index has been built on this page.

- [NEWEST\\_MODIFICATION](#)

The Log Sequence Number of the youngest modification.

- [OLDEST\\_MODIFICATION](#)

The Log Sequence Number of the oldest modification.

- [ACCESS\\_TIME](#)

An abstract number used to judge the first access time of the page.

- [TABLE\\_NAME](#)

The name of the table the page belongs to. This column is applicable only to pages with a [PAGE\\_TYPE](#) value of [INDEX](#).

- [INDEX\\_NAME](#)

The name of the index the page belongs to. This can be the name of a clustered index or a secondary index. This column is applicable only to pages with a [PAGE\\_TYPE](#) value of [INDEX](#).

- [NUMBER\\_RECORDS](#)

The number of records within the page.

- [DATA\\_SIZE](#)

The sum of the sizes of the records. This column is applicable only to pages with a [PAGE\\_TYPE](#) value of [INDEX](#).

- [COMPRESSED\\_SIZE](#)

The compressed page size. [NULL](#) for pages that are not compressed.

- [PAGE\\_STATE](#)

The page state. The following table shows the permitted values.

**Table 24.5 INNODB\_BUFFER\_PAGE.PAGE\_STATE Values**

| Page State                    | Description                                                                                           |
|-------------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">FILE_PAGE</a>     | A buffered file page                                                                                  |
| <a href="#">MEMORY</a>        | Contains a main memory object                                                                         |
| <a href="#">NOT_USED</a>      | In the free list                                                                                      |
| <a href="#">NULL</a>          | Clean compressed pages, compressed pages in the flush list, pages used as buffer pool watch sentinels |
| <a href="#">READY_FOR_USE</a> | A free page                                                                                           |
| <a href="#">REMOVE_HASH</a>   | Hash index should be removed before placing in the free list                                          |

- [IO\\_FIX](#)

Whether any I/O is pending for this page: [IO\\_NONE](#) = no pending I/O, [IO\\_READ](#) = read pending, [IO\\_WRITE](#) = write pending.

- [IS\\_OLD](#)

Whether the block is in the sublist of old blocks in the LRU list.

- [FREE\\_PAGE\\_CLOCK](#)

The value of the `freed_page_clock` counter when the block was the last placed at the head of the LRU list. The `freed_page_clock` counter tracks the number of blocks removed from the end of the LRU list.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE LIMIT 1\G
***** 1. row *****
 POOL_ID: 0
 BLOCK_ID: 0
 SPACE: 97
 PAGE_NUMBER: 2473
 PAGE_TYPE: INDEX
 FLUSH_TYPE: 1
 FIX_COUNT: 0
 IS_HASHED: YES
NEWEST_MODIFICATION: 733855581
OLDEST_MODIFICATION: 0
 ACCESS_TIME: 3378385672
 TABLE_NAME: `employees`.`salaries`
 INDEX_NAME: PRIMARY
NUMBER_RECORDS: 468
 DATA_SIZE: 14976
COMPRESSED_SIZE: 0
 PAGE_STATE: FILE_PAGE
 IO_FIX: IO_NONE
 IS_OLD: YES
FREE_PAGE_CLOCK: 66
```

## Notes

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The `INNODB_BUFFER_PAGE` table reports information about these pages until they are evicted from the buffer pool. For more information about how the InnoDB manages buffer pool data, see [Section 14.5.1, “Buffer Pool”](#).

### 24.4.3 The INFORMATION\_SCHEMA INNODB\_BUFFER\_PAGE\_LRU Table

The `INNODB_BUFFER_PAGE_LRU` table provides information about the pages in the InnoDB buffer pool; in particular, how they are ordered in the LRU list that determines which pages to `evict` from the buffer pool when it becomes full.

The `INNODB_BUFFER_PAGE_LRU` table has the same columns as the `INNODB_BUFFER_PAGE` table, except that the `INNODB_BUFFER_PAGE_LRU` table has `LRU_POSITION` and `COMPRESSED` columns instead of `BLOCK_ID` and `PAGE_STATE` columns.

For related usage information and examples, see [Section 14.16.5, “InnoDB INFORMATION\\_SCHEMA Buffer Pool Tables”](#).

#### Warning

Querying the `INNODB_BUFFER_PAGE_LRU` table can affect performance. Do not query this table on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

The [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table has these columns:

- [POOL\\_ID](#)

The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- [LRU\\_POSITION](#)

The position of the page in the LRU list.

- [SPACE](#)

The tablespace ID; the same value as [INNODB\\_SYS\\_TABLES.SPACE](#).

- [PAGE\\_NUMBER](#)

The page number.

- [PAGE\\_TYPE](#)

The page type. The following table shows the permitted values.

**Table 24.6 INNODB\_BUFFER\_PAGE\_LRU.PAGE\_TYPE Values**

| Page Type                         | Description                |
|-----------------------------------|----------------------------|
| <a href="#">ALLOCATED</a>         | Freshly allocated page     |
| <a href="#">BLOB</a>              | Uncompressed BLOB page     |
| <a href="#">COMPRESSED_BLOB2</a>  | Subsequent comp BLOB page  |
| <a href="#">COMPRESSED_BLOB</a>   | First compressed BLOB page |
| <a href="#">EXTENT_DESCRIPTOR</a> | Extent descriptor page     |
| <a href="#">FILE_SPACE_HEADER</a> | File space header          |
| <a href="#">IBUF_BITMAP</a>       | Insert buffer bitmap       |
| <a href="#">IBUF_FREE_LIST</a>    | Insert buffer free list    |
| <a href="#">IBUF_INDEX</a>        | Insert buffer index        |
| <a href="#">INDEX</a>             | B-tree node                |
| <a href="#">INODE</a>             | Index node                 |
| <a href="#">RTREE_INDEX</a>       | R-tree index               |
| <a href="#">SYSTEM</a>            | System page                |
| <a href="#">TRX_SYSTEM</a>        | Transaction system data    |
| <a href="#">UNDO_LOG</a>          | Undo log page              |
| <a href="#">UNKNOWN</a>           | Unknown                    |

- [FLUSH\\_TYPE](#)

The flush type.

- [FIX\\_COUNT](#)

The number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.

- [IS\\_HASHED](#)

Whether a hash index has been built on this page.

- **NEWEST\_MODIFICATION**

The Log Sequence Number of the youngest modification.

- **OLDEST\_MODIFICATION**

The Log Sequence Number of the oldest modification.

- **ACCESS\_TIME**

An abstract number used to judge the first access time of the page.

- **TABLE\_NAME**

The name of the table the page belongs to. This column is applicable only to pages with a **PAGE\_TYPE** value of **INDEX**.

- **INDEX\_NAME**

The name of the index the page belongs to. This can be the name of a clustered index or a secondary index. This column is applicable only to pages with a **PAGE\_TYPE** value of **INDEX**.

- **NUMBER\_RECORDS**

The number of records within the page.

- **DATA\_SIZE**

The sum of the sizes of the records. This column is applicable only to pages with a **PAGE\_TYPE** value of **INDEX**.

- **COMPRESSED\_SIZE**

The compressed page size. **NULL** for pages that are not compressed.

- **COMPRESSED**

Whether the page is compressed.

- **IO\_FIX**

Whether any I/O is pending for this page: **IO\_NONE** = no pending I/O, **IO\_READ** = read pending, **IO\_WRITE** = write pending.

- **IS\_OLD**

Whether the block is in the sublist of old blocks in the LRU list.

- **FREE\_PAGE\_CLOCK**

The value of the **freed\_page\_clock** counter when the block was the last placed at the head of the LRU list. The **freed\_page\_clock** counter tracks the number of blocks removed from the end of the LRU list.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU LIMIT 1\G
***** 1. row *****
 POOL_ID: 0
 LRU_POSITION: 0
 SPACE: 97
 PAGE_NUMBER: 1984
 PAGE_TYPE: INDEX
 FLUSH_TYPE: 1
 FIX_COUNT: 0
```

```
IS_HASHED: YES
NEWEST_MODIFICATION: 719490396
OLDEST_MODIFICATION: 0
 ACCESS_TIME: 3378383796
 TABLE_NAME: `employees`.`salaries`
 INDEX_NAME: PRIMARY
 NUMBER_RECORDS: 468
 DATA_SIZE: 14976
COMPRESSED_SIZE: 0
COMPRESSED: NO
 IO_FIX: IO_NONE
 IS_OLD: YES
FREE_PAGE_CLOCK: 0
```

## Notes

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION\\_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.
- Querying this table can require MySQL to allocate a large block of contiguous memory, more than 64 bytes times the number of active pages in the buffer pool. This allocation could potentially cause an out-of-memory error, especially for systems with multi-gigabyte buffer pools.
- Querying this table requires MySQL to lock the data structure representing the buffer pool while traversing the LRU list, which can reduce concurrency, especially for systems with multi-gigabyte buffer pools.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table reports information about these pages until they are evicted from the buffer pool. For more information about how the InnoDB manages buffer pool data, see [Section 14.5.1, “Buffer Pool”](#).

### 24.4.4 The INFORMATION\_SCHEMA INNODB\_BUFFER\_POOL\_STATS Table

The [INNODB\\_BUFFER\\_POOL\\_STATS](#) table provides much of the same buffer pool information provided in [SHOW ENGINE INNODB STATUS](#) output. Much of the same information may also be obtained using InnoDB buffer pool [server status variables](#).

The idea of making pages in the buffer pool “young” or “not young” refers to transferring them between the [sublists](#) at the head and tail of the buffer pool data structure. Pages made “young” take longer to age out of the buffer pool, while pages made “not young” are moved much closer to the point of [eviction](#).

For related usage information and examples, see [Section 14.16.5, “InnoDB INFORMATION\\_SCHEMA Buffer Pool Tables”](#).

The [INNODB\\_BUFFER\\_POOL\\_STATS](#) table has these columns:

- [POOL\\_ID](#)

The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- [POOL\\_SIZE](#)

The InnoDB buffer pool size in pages.

- [FREE\\_BUFFERS](#)

The number of free pages in the InnoDB buffer pool.

- [DATABASE\\_PAGES](#)

The number of pages in the [InnoDB](#) buffer pool containing data. This number includes both dirty and clean pages.

- [OLD\\_DATABASE\\_PAGES](#)

The number of pages in the [old](#) buffer pool sublist.

- [MODIFIED\\_DATABASE\\_PAGES](#)

The number of modified (dirty) database pages.

- [PENDING\\_DECOMPRESS](#)

The number of pages pending decompression.

- [PENDING\\_READS](#)

The number of pending reads.

- [PENDING\\_FLUSH\\_LRU](#)

The number of pages pending flush in the LRU.

- [PENDING\\_FLUSH\\_LIST](#)

The number of pages pending flush in the flush list.

- [PAGES\\_MADE\\_YOUNG](#)

The number of pages made young.

- [PAGES\\_NOT\\_MADE\\_YOUNG](#)

The number of pages not made young.

- [PAGES\\_MADE\\_YOUNG\\_RATE](#)

The number of pages made young per second (pages made young since the last printout / time elapsed).

- [PAGES\\_MADE\\_NOT\\_YOUNG\\_RATE](#)

The number of pages not made per second (pages not made young since the last printout / time elapsed).

- [NUMBER\\_PAGES\\_READ](#)

The number of pages read.

- [NUMBER\\_PAGES\\_CREATED](#)

The number of pages created.

- [NUMBER\\_PAGES\\_WRITTEN](#)

The number of pages written.

- [PAGES\\_READ\\_RATE](#)

The number of pages read per second (pages read since the last printout / time elapsed).

- [PAGES\\_CREATE\\_RATE](#)

The number of pages created per second (pages created since the last printout / time elapsed).

- [PAGES\\_WRITTEN\\_RATE](#)

The number of pages written per second (pages written since the last printout / time elapsed).

- [NUMBER\\_PAGES\\_GET](#)

The number of logical read requests.

- [HIT\\_RATE](#)

The buffer pool hit rate.

- [YOUNG\\_MAKE\\_PER\\_THOUSAND\\_GETS](#)

The number of pages made young per thousand gets.

- [NOT\\_YOUNG\\_MAKE\\_PER\\_THOUSAND\\_GETS](#)

The number of pages not made young per thousand gets.

- [NUMBER\\_PAGES\\_READ\\_AHEAD](#)

The number of pages read ahead.

- [NUMBER\\_READ\\_AHEAD\\_EVICTED](#)

The number of pages read into the [InnoDB](#) buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries.

- [READ\\_AHEAD\\_RATE](#)

The read-ahead rate per second (pages read ahead since the last printout / time elapsed).

- [READ\\_AHEAD\\_EVICTED\\_RATE](#)

The number of read-ahead pages evicted without access per second (read-ahead pages not accessed since the last printout / time elapsed).

- [LRU\\_IO\\_TOTAL](#)

Total LRU I/O.

- [LRU\\_IO\\_CURRENT](#)

LRU I/O for the current interval.

- [UNCOMPRESS\\_TOTAL](#)

The total number of pages decompressed.

- [UNCOMPRESS\\_CURRENT](#)

The number of pages decompressed in the current interval.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_POOL_STATS\G
***** 1. row *****
 POOL_ID: 0
 POOL_SIZE: 8192
 FREE_BUFFERS: 1
DATABASE_PAGES: 8085
OLD_DATABASE_PAGES: 2964
```

```
MODIFIED_DATABASE_PAGES: 0
PENDING_DECOMPRESS: 0
PENDING_READS: 0
PENDING_FLUSH_LRU: 0
PENDING_FLUSH_LIST: 0
PAGES_MADE_YOUNG: 22821
PAGES_NOT_MADE_YOUNG: 3544303
PAGES_MADE_YOUNG_RATE: 357.62602199870594
PAGES_MADE_NOT_YOUNG_RATE: 0
NUMBER_PAGES_READ: 2389
NUMBER_PAGES_CREATED: 12385
NUMBER_PAGES_WRITTEN: 13111
PAGES_READ_RATE: 0
PAGES_CREATE_RATE: 0
PAGES_WRITTEN_RATE: 0
NUMBER_PAGES_GET: 33322210
HIT_RATE: 1000
YOUNG_MAKE_PER_THOUSAND_GETS: 18
NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
NUMBER_PAGES_READ_AHEAD: 2024
NUMBER_READ_AHEAD_EVICTED: 0
READ_AHEAD_RATE: 0
READ_AHEAD_EVICTED_RATE: 0
LRU_IO_TOTAL: 0
LRU_IO_CURRENT: 0
UNCOMPRESS_TOTAL: 0
UNCOMPRESS_CURRENT: 0
```

## Notes

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

### 24.4.5 The INFORMATION\_SCHEMA INNODB\_CMP and INNODB\_CMP\_RESET Tables

The `INNODB_CMP` and `INNODB_CMP_RESET` tables provide status information on operations related to compressed InnoDB tables.

The `INNODB_CMP` and `INNODB_CMP_RESET` tables have these columns:

- `PAGE_SIZE`

The compressed page size in bytes.

- `COMPRESS_OPS`

The number of times a B-tree page of size `PAGE_SIZE` has been compressed. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.

- `COMPRESS_OPS_OK`

The number of times a B-tree page of size `PAGE_SIZE` has been successfully compressed. This count should never exceed `COMPRESS_OPS`.

- `COMPRESS_TIME`

The total time in seconds used for attempts to compress B-tree pages of size `PAGE_SIZE`.

- `UNCOMPRESS_OPS`

The number of times a B-tree page of size `PAGE_SIZE` has been uncompressed. B-tree pages are uncompressed whenever compression fails or at first access when the uncompressed page does not exist in the buffer pool.

- `UNCOMPRESS_TIME`

The total time in seconds used for uncompressing B-tree pages of the size `PAGE_SIZE`.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP\G
***** 1. row *****
 page_size: 1024
 compress_ops: 0
compress_ops_ok: 0
 compress_time: 0
 uncompress_ops: 0
uncompress_time: 0
***** 2. row *****
 page_size: 2048
 compress_ops: 0
compress_ops_ok: 0
 compress_time: 0
 uncompress_ops: 0
uncompress_time: 0
***** 3. row *****
 page_size: 4096
 compress_ops: 0
compress_ops_ok: 0
 compress_time: 0
 uncompress_ops: 0
uncompress_time: 0
***** 4. row *****
 page_size: 8192
 compress_ops: 86955
compress_ops_ok: 81182
 compress_time: 27
 uncompress_ops: 26828
uncompress_time: 5
***** 5. row *****
 page_size: 16384
 compress_ops: 0
compress_ops_ok: 0
 compress_time: 0
 uncompress_ops: 0
uncompress_time: 0
```

## Notes

- Use these tables to measure the effectiveness of `InnoDB` table `compression` in your database.
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For usage information, see [Section 14.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#) and [Section 14.16.1.3, “Using the Compression Information Schema Tables”](#). For general information about `InnoDB` table compression, see [Section 14.9, “InnoDB Table and Page Compression”](#).

## 24.4.6 The INFORMATION\_SCHEMA INNODB\_CMPMEM and INNODB\_CMPMEM\_RESET Tables

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables provide status information on compressed pages within the `InnoDB` buffer pool.

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables have these columns:

- `PAGE_SIZE`

The block size in bytes. Each record of this table describes blocks of this size.

- `BUFFER_POOL_INSTANCE`

A unique identifier for the buffer pool instance.

- `PAGES_USED`

The number of blocks of size `PAGE_SIZE` that are currently in use.

- `PAGES_FREE`

The number of blocks of size `PAGE_SIZE` that are currently available for allocation. This column shows the external fragmentation in the memory pool. Ideally, these numbers should be at most 1.

- `RELOCATION_OPS`

The number of times a block of size `PAGE_SIZE` has been relocated. The buddy system can relocate the allocated “buddy neighbor” of a freed block when it tries to form a bigger freed block. Reading from the `INNODB_CMPMEM_RESET` table resets this count.

- `RELOCATION_TIME`

The total time in microseconds used for relocating blocks of size `PAGE_SIZE`. Reading from the table `INNODB_CMPMEM_RESET` resets this count.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMPMEM\G
***** 1. row *****
 page_size: 1024
buffer_pool_instance: 0
 pages_used: 0
 pages_free: 0
 relocation_ops: 0
 relocation_time: 0
***** 2. row *****
 page_size: 2048
buffer_pool_instance: 0
 pages_used: 0
 pages_free: 0
 relocation_ops: 0
 relocation_time: 0
***** 3. row *****
 page_size: 4096
buffer_pool_instance: 0
 pages_used: 0
 pages_free: 0
 relocation_ops: 0
 relocation_time: 0
***** 4. row *****
 page_size: 8192
buffer_pool_instance: 0
 pages_used: 7673
 pages_free: 15
 relocation_ops: 4638
 relocation_time: 0
***** 5. row *****
 page_size: 16384
buffer_pool_instance: 0
 pages_used: 0
 pages_free: 0
 relocation_ops: 0
 relocation_time: 0
```

## Notes

- Use these tables to measure the effectiveness of [InnoDB](#) table [compression](#) in your database.
- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION\\_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.
- For usage information, see [Section 14.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#) and [Section 14.16.1.3, “Using the Compression Information Schema Tables”](#). For general information about [InnoDB](#) table compression, see [Section 14.9, “InnoDB Table and Page Compression”](#).

### 24.4.7 The INFORMATION\_SCHEMA INNODB\_CMP\_PER\_INDEX and INNODB\_CMP\_PER\_INDEX\_RESET Tables

The [INNODB\\_CMP\\_PER\\_INDEX](#) and [INNODB\\_CMP\\_PER\\_INDEX\\_RESET](#) tables provide status information on operations related to [compressed](#) [InnoDB](#) tables and indexes, with separate statistics for each combination of database, table, and index, to help you evaluate the performance and usefulness of compression for specific tables.

For a compressed [InnoDB](#) table, both the table data and all the [secondary indexes](#) are compressed. In this context, the table data is treated as just another index, one that happens to contain all the columns: the [clustered index](#).

The [INNODB\\_CMP\\_PER\\_INDEX](#) and [INNODB\\_CMP\\_PER\\_INDEX\\_RESET](#) tables have these columns:

- [DATABASE\\_NAME](#)

The schema (database) containing the applicable table.

- [TABLE\\_NAME](#)

The table to monitor for compression statistics.

- [INDEX\\_NAME](#)

The index to monitor for compression statistics.

- [COMPRESS\\_OPS](#)

The number of compression operations attempted. [Pages](#) are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.

- [COMPRESS\\_OPS\\_OK](#)

The number of successful compression operations. Subtract from the [COMPRESS\\_OPS](#) value to get the number of [compression failures](#). Divide by the [COMPRESS\\_OPS](#) value to get the percentage of compression failures.

- [COMPRESS\\_TIME](#)

The total time in seconds used for compressing data in this index.

- [UNCOMPRESS\\_OPS](#)

The number of uncompression operations performed. Compressed [InnoDB](#) pages are uncompressed whenever compression [fails](#), or the first time a compressed page is accessed in the [buffer pool](#) and the uncompressed page does not exist.

- [UNCOMPRESS\\_TIME](#)

The total time in seconds used for uncompressing data in this index.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX\G
***** 1. row *****
 database_name: employees
 table_name: salaries
 index_name: PRIMARY
 compress_ops: 0
compress_ops_ok: 0
 compress_time: 0
 uncompress_ops: 23451
uncompress_time: 4
***** 2. row *****
 database_name: employees
 table_name: salaries
 index_name: emp_no
 compress_ops: 0
compress_ops_ok: 0
 compress_time: 0
 uncompress_ops: 1597
uncompress_time: 0
```

## Notes

- Use these tables to measure the effectiveness of [InnoDB table compression](#) for specific tables, indexes, or both.
- You must have the [PROCESS](#) privilege to query these tables.
- Use the [INFORMATION\\_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of these tables, including data types and default values.
- Because collecting separate measurements for every index imposes substantial performance overhead, [INNODB\\_CMP\\_PER\\_INDEX](#) and [INNODB\\_CMP\\_PER\\_INDEX\\_RESET](#) statistics are not gathered by default. You must enable the [innodb\\_cmp\\_per\\_index\\_enabled](#) system variable before performing the operations on compressed tables that you want to monitor.
- For usage information, see [Section 14.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#) and [Section 14.16.1.3, “Using the Compression Information Schema Tables”](#). For general information about [InnoDB](#) table compression, see [Section 14.9, “InnoDB Table and Page Compression”](#).

## 24.4.8 The INFORMATION\_SCHEMA INNODB\_FT\_BEING\_DELETED Table

The [INNODB\\_FT\\_BEING\\_DELETED](#) table provides a snapshot of the [INNODB\\_FT\\_DELETED](#) table; it is used only during an [OPTIMIZE TABLE](#) maintenance operation. When [OPTIMIZE TABLE](#) is run, the [INNODB\\_FT\\_BEING\\_DELETED](#) table is emptied, and [DOC\\_ID](#) values are removed from the [INNODB\\_FT\\_DELETED](#) table. Because the contents of [INNODB\\_FT\\_BEING\\_DELETED](#) typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running [OPTIMIZE TABLE](#) on tables with [FULLTEXT](#) indexes, see [Section 12.10.6, “Fine-Tuning MySQL Full-Text Search”](#).

This table is empty initially. Before querying it, set the value of the [innodb\\_ft\\_aux\\_table](#) system variable to the name (including the database name) of the table that contains the [FULLTEXT](#) index; for example `test/articles`. The output appears similar to the example provided for the [INNODB\\_FT\\_DELETED](#) table.

For related usage information and examples, see [Section 14.16.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

The [INNODB\\_FT\\_BEING\\_DELETED](#) table has these columns:

- [DOC\\_ID](#)

The document ID of the row that is in the process of being deleted. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column. This value is used when you do text searches, to skip rows in the [INNODB\\_FT\\_INDEX\\_TABLE](#) table before data for deleted rows is physically removed from the [FULLTEXT](#) index by an [OPTIMIZE TABLE](#) statement. For more information, see [Optimizing InnoDB Full-Text Indexes](#).

## Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION\\_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.
- For more information about InnoDB FULLTEXT search, see [Section 14.6.2.4, “InnoDB Full-Text Indexes”](#), and [Section 12.10, “Full-Text Search Functions”](#).

### 24.4.9 The INFORMATION\_SCHEMA INNODB\_FT\_CONFIG Table

The [INNODB\\_FT\\_CONFIG](#) table provides metadata about the [FULLTEXT](#) index and associated processing for an InnoDB table.

This table is empty initially. Before querying it, set the value of the [innodb\\_ft\\_aux\\_table](#) system variable to the name (including the database name) of the table that contains the [FULLTEXT](#) index; for example `test/articles`.

For related usage information and examples, see [Section 14.16.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

The [INNODB\\_FT\\_CONFIG](#) table has these columns:

- [KEY](#)

The name designating an item of metadata for an InnoDB table containing a [FULLTEXT](#) index.

The values for this column might change, depending on the needs for performance tuning and debugging for InnoDB full-text processing. The key names and their meanings include:

- [optimize\\_checkpoint\\_limit](#): The number of seconds after which an [OPTIMIZE TABLE](#) run stops.
- [synced\\_doc\\_id](#): The next [DOC\\_ID](#) to be issued.
- [stopword\\_table\\_name](#): The [database/table](#) name for a user-defined stopword table. The [VALUE](#) column is empty if there is no user-defined stopword table.
- [use\\_stopword](#): Indicates whether a stopword table is used, which is defined when the [FULLTEXT](#) index is created.
- [VALUE](#)

The value associated with the corresponding [KEY](#) column, reflecting some limit or current value for an aspect of a [FULLTEXT](#) index for an InnoDB table.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+-----+-----+
| KEY | VALUE |
+-----+-----+
```

|                           |                   |
|---------------------------|-------------------|
| optimize_checkpoint_limit | 180               |
| synced_doc_id             | 0                 |
| stopword_table_name       | test/my_stopwords |
| use_stopword              | 1                 |

## Notes

- This table is intended only for internal configuration. It is not intended for statistical information purposes.
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For more information about `InnoDB FULLTEXT` search, see [Section 14.6.2.4, “InnoDB Full-Text Indexes”](#), and [Section 12.10, “Full-Text Search Functions”](#).

## 24.4.10 The INFORMATION\_SCHEMA INNODB\_FT\_DEFAULT\_STOPWORD Table

The `INNODB_FT_DEFAULT_STOPWORD` table holds a list of `stopwords` that are used by default when creating a `FULLTEXT` index on `InnoDB` tables. For information about the default `InnoDB` stopword list and how to define your own stopword lists, see [Section 12.10.4, “Full-Text Stopwords”](#).

For related usage information and examples, see [Section 14.16.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

The `INNODB_FT_DEFAULT_STOPWORD` table has these columns:

- `value`

A word that is used by default as a stopword for `FULLTEXT` indexes on `InnoDB` tables. This is not used if you override the default stopword processing with either the `innodb_ft_server_stopword_table` or the `innodb_ft_user_stopword_table` system variable.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;
+-----+
| value |
+-----+
| a |
| about |
| an |
| are |
| as |
| at |
| be |
| by |
| com |
| de |
| en |
| for |
| from |
| how |
| i |
| in |
| is |
| it |
| la |
| of |
| on |
+-----+
```

```
| or |
| that |
| the |
| this |
| to |
| was |
| what |
| when |
| where |
| who |
| will |
| with |
| und |
| the |
| www |
+-----+
36 rows in set (0.00 sec)
```

## Notes

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For more information about InnoDB FULLTEXT search, see [Section 14.6.2.4, “InnoDB Full-Text Indexes”](#), and [Section 12.10, “Full-Text Search Functions”](#).

### 24.4.11 The INFORMATION\_SCHEMA INNODB\_FT\_DELETED Table

The `INNODB_FT_DELETED` table stores rows that are deleted from the `FULLTEXT` index for an InnoDB table. To avoid expensive index reorganization during DML operations for an InnoDB `FULLTEXT` index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue an `OPTIMIZE TABLE` statement for the InnoDB table. For more information, see [Optimizing InnoDB Full-Text Indexes](#).

This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index; for example `test/articles`.

For related usage information and examples, see [Section 14.16.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

The `INNODB_FT_DELETED` table has these columns:

- `DOC_ID`

The document ID of the newly deleted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column. This value is used when you do text searches, to skip rows in the `INNODB_FT_INDEX_TABLE` table before data for deleted rows is physically removed from the `FULLTEXT` index by an `OPTIMIZE TABLE` statement. For more information, see [Optimizing InnoDB Full-Text Indexes](#).

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+-----+
| DOC_ID |
+-----+
| 6 |
| 7 |
| 8 |
```

```
+-----+
```

## Notes

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For more information about `InnoDB FULLTEXT` search, see [Section 14.6.2.4, “InnoDB Full-Text Indexes”](#), and [Section 12.10, “Full-Text Search Functions”](#).

## 24.4.12 The INFORMATION\_SCHEMA INNODB\_FT\_INDEX\_CACHE Table

The `INNODB_FT_INDEX_CACHE` table provides token information about newly inserted rows in a `FULLTEXT` index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when `OPTIMIZE TABLE` is run, when the server is shut down, or when the cache size exceeds a limit defined by the `innodb_ft_cache_size` or `innodb_ft_total_cache_size` system variable.

This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index; for example `test/articles`.

For related usage information and examples, see [Section 14.16.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

The `INNODB_FT_INDEX_CACHE` table has these columns:

- `WORD`

A word extracted from the text of a newly inserted row.

- `FIRST_DOC_ID`

The first document ID in which this word appears in the `FULLTEXT` index.

- `LAST_DOC_ID`

The last document ID in which this word appears in the `FULLTEXT` index.

- `DOC_COUNT`

The number of rows in which this word appears in the `FULLTEXT` index. The same word can occur several times within the cache table, once for each combination of `DOC_ID` and `POSITION` values.

- `DOC_ID`

The document ID of the newly inserted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by `InnoDB` when the table contains no suitable column.

- `POSITION`

The position of this particular instance of the word within the relevant document identified by the `DOC_ID` value. The value does not represent an absolute position; it is an offset added to the `POSITION` of the previous instance of that word.

## Notes

- This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT`

index; for example `test/articles`. The following example demonstrates how to use the `innodb_ft_aux_table` system variable to show information about a `FULLTEXT` index for a specified table.

```
mysql> USE test;

mysql> CREATE TABLE articles (
 id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
 title VARCHAR(200),
 body TEXT,
 FULLTEXT (title,body)
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
 ('MySQL Tutorial','DBMS stands for DataBase ...'),
 ('How To Use MySQL Well','After you went through a ...'),
 ('Optimizing MySQL','In this tutorial we show ...'),
 ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
 ('MySQL vs. YourSQL','In the following database comparison ...'),
 ('MySQL Security','When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';

mysql> SELECT WORD, DOC_COUNT, DOC_ID, POSITION
 FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
+-----+-----+-----+-----+
| WORD | DOC_COUNT | DOC_ID | POSITION |
+-----+-----+-----+-----+
| 1001 | 1 | 4 | 0 |
| after | 1 | 2 | 22 |
| comparison | 1 | 5 | 44 |
| configured | 1 | 6 | 20 |
| database | 2 | 1 | 31 |
+-----+-----+-----+-----+
```

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For more information about `InnoDB FULLTEXT` search, see [Section 14.6.2.4, “InnoDB Full-Text Indexes”](#), and [Section 12.10, “Full-Text Search Functions”](#).

#### 24.4.13 The INFORMATION\_SCHEMA INNODB\_FT\_INDEX\_TABLE Table

The `INNODB_FT_INDEX_TABLE` table provides information about the inverted index used to process text searches against the `FULLTEXT` index of an `InnoDB` table.

This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index; for example `test/articles`.

For related usage information and examples, see [Section 14.16.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

The `INNODB_FT_INDEX_TABLE` table has these columns:

- `WORD`

A word extracted from the text of the columns that are part of a `FULLTEXT`.

- `FIRST_DOC_ID`

The first document ID in which this word appears in the `FULLTEXT` index.

- `LAST_DOC_ID`

The last document ID in which this word appears in the `FULLTEXT` index.

- `DOC_COUNT`

The number of rows in which this word appears in the `FULLTEXT` index. The same word can occur several times within the cache table, once for each combination of `DOC_ID` and `POSITION` values.

- `DOC_ID`

The document ID of the row containing the word. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by `InnoDB` when the table contains no suitable column.

- `POSITION`

The position of this particular instance of the word within the relevant document identified by the `DOC_ID` value.

## Notes

- This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index; for example `test/articles`. The following example demonstrates how to use the `innodb_ft_aux_table` system variable to show information about a `FULLTEXT` index for a specified table. Before information for newly inserted rows appears in `INNODB_FT_INDEX_TABLE`, the `FULLTEXT` index cache must be flushed to disk. This is accomplished by running an `OPTIMIZE TABLE` operation on the indexed table with the `innodb_optimize_fulltext_only` system variable enabled. (The example disables that variable again at the end because it is intended to be enabled only temporarily.)

```
mysql> USE test;
mysql> CREATE TABLE articles (
 id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
 title VARCHAR(200),
 body TEXT,
 FULLTEXT (title,body)
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
 ('MySQL Tutorial','DBMS stands for DataBase ...'),
 ('How To Use MySQL Well','After you went through a ...'),
 ('Optimizing MySQL','In this tutorial we show ...'),
 ('1001 MySQL Tricks','1. Never run mysqld as root. 2.'),
 ('MySQL vs. YourSQL','In the following database comparison ...'),
 ('MySQL Security','When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;

mysql> OPTIMIZE TABLE articles;
+-----+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+-----+
| test.articles | optimize | status | OK |
+-----+-----+-----+

mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';

mysql> SELECT WORD, DOC_COUNT, DOC_ID, POSITION
 FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 5;
+-----+-----+-----+-----+
| WORD | DOC_COUNT | DOC_ID | POSITION |
+-----+-----+-----+-----+
| 1001 | 1 | 4 | 0 |
| after | 1 | 2 | 22 |
| comparison | 1 | 5 | 44 |
+-----+-----+-----+-----+
```

```
| configured | 1 | 6 | 20 |
| database | 2 | 1 | 31 |
+-----+-----+-----+
mysql> SET GLOBAL innodb_optimize_fulltext_only=OFF;
```

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For more information about `InnoDB FULLTEXT` search, see [Section 14.6.2.4, “InnoDB Full-Text Indexes”](#), and [Section 12.10, “Full-Text Search Functions”](#).

#### 24.4.14 The INFORMATION\_SCHEMA INNODB\_LOCKS Table

The `INNODB_LOCKS` table provides information about each lock that an `InnoDB` transaction has requested but not yet acquired, and each lock that a transaction holds that is blocking another transaction.

##### Note

This table is deprecated as of MySQL 5.7.14 and is removed in MySQL 8.0.

The `INNODB_LOCKS` table has these columns:

- `LOCK_ID`

A unique lock ID number, internal to `InnoDB`. Treat it as an opaque string. Although `LOCK_ID` currently contains `TRX_ID`, the format of the data in `LOCK_ID` is subject to change at any time. Do not write applications that parse the `LOCK_ID` value.

- `LOCK_TRX_ID`

The ID of the transaction holding the lock. To obtain details about the transaction, join this column with the `TRX_ID` column of the `INNODB_TRX` table.

- `LOCK_MODE`

How the lock is requested. Permitted lock mode descriptors are `S`, `X`, `IS`, `IX`, `GAP`, `AUTO_INC`, and `UNKNOWN`. Lock mode descriptors may be used in combination to identify particular lock modes. For information about `InnoDB` lock modes, see [Section 14.7.1, “InnoDB Locking”](#).

- `LOCK_TYPE`

The type of lock. Permitted values are `RECORD` for a row-level lock, `TABLE` for a table-level lock.

- `LOCK_TABLE`

The name of the table that has been locked or contains locked records.

- `LOCK_INDEX`

The name of the index, if `LOCK_TYPE` is `RECORD`; otherwise `NULL`.

- `LOCK_SPACE`

The tablespace ID of the locked record, if `LOCK_TYPE` is `RECORD`; otherwise `NULL`.

- `LOCK_PAGE`

The page number of the locked record, if `LOCK_TYPE` is `RECORD`; otherwise `NULL`.

- **LOCK\_REC**

The heap number of the locked record within the page, if `LOCK_TYPE` is `RECORD`; otherwise `NULL`.

- **LOCK\_DATA**

The data associated with the lock, if any. A value is shown if the `LOCK_TYPE` is `RECORD`, otherwise the value is `NULL`. Primary key values of the locked record are shown for a lock placed on the primary key index. Secondary index values of the locked record are shown for a lock placed on a unique secondary index. Secondary index values are shown with primary key values appended if the secondary index is not unique. If there is no primary key, `LOCK_DATA` shows either the key values of a selected unique index or the unique InnoDB internal row ID number, according to the rules governing InnoDB clustered index use (see [Section 14.6.2.1, “Clustered and Secondary Indexes”](#)). `LOCK_DATA` reports “supremum pseudo-record” for a lock taken on a supremum pseudo-record. If the page containing the locked record is not in the buffer pool because it was written to disk while the lock was held, InnoDB does not fetch the page from disk. Instead, `LOCK_DATA` reports `NULL`.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_LOCKS\G
***** 1. row *****
lock_id: 3723:72:3:2
lock trx_id: 3723
lock_mode: X
lock_type: RECORD
lock_table: `mysql`.`t`
lock_index: PRIMARY
lock_space: 72
lock_page: 3
lock_rec: 2
lock_data: 1, 9
***** 2. row *****
lock_id: 3722:72:3:2
lock trx_id: 3722
lock_mode: S
lock_type: RECORD
lock_table: `mysql`.`t`
lock_index: PRIMARY
lock_space: 72
lock_page: 3
lock_rec: 2
lock_data: 1, 9
```

## Notes

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in [Section 14.16.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For usage information, see [Section 14.16.2.1, “Using InnoDB Transaction and Locking Information”](#).

### 24.4.15 The INFORMATION\_SCHEMA INNODB\_LOCK\_WAITS Table

The `INNODB_LOCK_WAITS` table contains one or more rows for each blocked InnoDB transaction, indicating the lock it has requested and any locks that are blocking that request.

#### Note

This table is deprecated as of MySQL 5.7.14 and is removed in MySQL 8.0.

The `INNODB_LOCK_WAITS` table has these columns:

- `REQUESTING_TRX_ID`

The ID of the requesting (blocked) transaction.

- `REQUESTED_LOCK_ID`

The ID of the lock for which a transaction is waiting. To obtain details about the lock, join this column with the `LOCK_ID` column of the `INNODB_LOCKS` table.

- `BLOCKING_TRX_ID`

The ID of the blocking transaction.

- `BLOCKING_LOCK_ID`

The ID of a lock held by a transaction blocking another transaction from proceeding. To obtain details about the lock, join this column with the `LOCK_ID` column of the `INNODB_LOCKS` table.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_LOCK_WAIT\G
***** 1. row *****
requesting_trx_id: 3396
requested_lock_id: 3396:91:3:2
 blocking_trx_id: 3395
blocking_lock_id: 3395:91:3:2
```

## Notes

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in [Section 14.16.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For usage information, see [Section 14.16.2.1, “Using InnoDB Transaction and Locking Information”](#).

## 24.4.16 The INFORMATION\_SCHEMA INNODB\_METRICS Table

The `INNODB_METRICS` table provides a wide variety of `InnoDB` performance information, complementing the specific focus areas of the Performance Schema tables for `InnoDB`. With simple queries, you can check the overall health of the system. With more detailed queries, you can diagnose issues such as performance bottlenecks, resource shortages, and application issues.

Each monitor represents a point within the `InnoDB` source code that is instrumented to gather counter information. Each counter can be started, stopped, and reset. You can also perform these actions for a group of counters using their common module name.

By default, relatively little data is collected. To start, stop, and reset counters, set one of the system variables `innodb_monitor_enable`, `innodb_monitor_disable`, `innodb_monitor_reset`, or `innodb_monitor_reset_all`, using the name of the counter, the name of the module, a wildcard match for such a name using the “%” character, or the special keyword `all`.

For usage information, see [Section 14.16.6, “InnoDB INFORMATION\\_SCHEMA Metrics Table”](#).

The `INNODB_METRICS` table has these columns:

- `NAME`

A unique name for the counter.

- [SUBSYSTEM](#)

The aspect of [InnoDB](#) that the metric applies to.

- [COUNT](#)

The value since the counter was enabled.

- [MAX\\_COUNT](#)

The maximum value since the counter was enabled.

- [MIN\\_COUNT](#)

The minimum value since the counter was enabled.

- [AVG\\_COUNT](#)

The average value since the counter was enabled.

- [COUNT\\_RESET](#)

The counter value since it was last reset. (The [\\_RESET](#) columns act like the lap counter on a stopwatch: you can measure the activity during some time interval, while the cumulative figures are still available in [COUNT](#), [MAX\\_COUNT](#), and so on.)

- [MAX\\_COUNT\\_RESET](#)

The maximum counter value since it was last reset.

- [MIN\\_COUNT\\_RESET](#)

The minimum counter value since it was last reset.

- [AVG\\_COUNT\\_RESET](#)

The average counter value since it was last reset.

- [TIME\\_ENABLED](#)

The timestamp of the last start.

- [TIME\\_DISABLED](#)

The timestamp of the last stop.

- [TIME\\_ELAPSED](#)

The elapsed time in seconds since the counter started.

- [TIME\\_RESET](#)

The timestamp of the last reset.

- [STATUS](#)

Whether the counter is still running ([enabled](#)) or stopped ([disabled](#)).

- [TYPE](#)

Whether the item is a cumulative counter, or measures the current value of some resource.

- [COMMENT](#)

The counter description.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='dml_inserts' \G
***** 1. row *****
 NAME: dml_inserts
 SUBSYSTEM: dml
 COUNT: 3
 MAX_COUNT: 3
 MIN_COUNT: NULL
 AVG_COUNT: 0.046153846153846156
COUNT_RESET: 3
MAX_COUNT_RESET: 3
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
 TIME_ENABLED: 2014-12-04 14:18:28
 TIME_DISABLED: NULL
 TIME_ELAPSED: 65
 TIME_RESET: NULL
 STATUS: enabled
 TYPE: status_counter
 COMMENT: Number of rows inserted
```

## Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION\\_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.
- Transaction counter [COUNT](#) values may differ from the number of transaction events reported in Performance Schema [EVENTS\\_TRANSACTIONS\\_SUMMARY](#) tables. [InnoDB](#) counts only those transactions that it executes, whereas Performance Schema collects events for all non-aborted transactions initiated by the server, including empty transactions.

## 24.4.17 The INFORMATION\_SCHEMA INNODB\_SYS\_COLUMNS Table

The [INNODB\\_SYS\\_COLUMNS](#) table provides metadata about [InnoDB](#) table columns, equivalent to the information from the [SYS\\_COLUMNS](#) table in the [InnoDB](#) data dictionary.

For related usage information and examples, see [Section 14.16.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

The [INNODB\\_SYS\\_COLUMNS](#) table has these columns:

- [TABLE\\_ID](#)

An identifier representing the table associated with the column; the same value as [INNODB\\_SYS\\_TABLES.TABLE\\_ID](#).

- [NAME](#)

The name of the column. These names can be uppercase or lowercase depending on the [lower\\_case\\_table\\_names](#) setting. There are no special system-reserved names for columns.

- [POS](#)

The ordinal position of the column within the table, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps. The [POS](#) value for a virtual generated column encodes the column sequence number and ordinal position of the column. For more information, see the [POS](#) column description in [Section 24.4.26, “The INFORMATION\\_SCHEMA INNODB\\_SYS\\_VIRTUAL Table”](#).

- **MTYPE**

Stands for “main type”. A numeric identifier for the column type. 1 = `VARCHAR`, 2 = `CHAR`, 3 = `FIXBINARY`, 4 = `BINARY`, 5 = `BLOB`, 6 = `INT`, 7 = `SYS_CHILD`, 8 = `SYS`, 9 = `FLOAT`, 10 = `DOUBLE`, 11 = `DECIMAL`, 12 = `VARMYSQL`, 13 = `MYSQL`, 14 = `GEOMETRY`.

- **PRTYPE**

The `InnoDB` “precise type”, a binary value with bits representing MySQL data type, character set code, and nullability.

- **LEN**

The column length, for example 4 for `INT` and 8 for `BIGINT`. For character columns in multibyte character sets, this length value is the maximum length in bytes needed to represent a definition such as `VARCHAR(N)`; that is, it might be  $2^*N$ ,  $3^*N$ , and so on depending on the character encoding.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_COLUMNS where TABLE_ID = 71\G
***** 1. row *****
TABLE_ID: 71
 NAME: col1
 POS: 0
 MTYPE: 6
 PRTYPE: 1027
 LEN: 4
***** 2. row *****
TABLE_ID: 71
 NAME: col2
 POS: 1
 MTYPE: 2
 PRTYPE: 524542
 LEN: 10
***** 3. row *****
TABLE_ID: 71
 NAME: col3
 POS: 2
 MTYPE: 1
 PRTYPE: 524303
 LEN: 10
```

## Notes

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

### 24.4.18 The INFORMATION\_SCHEMA INNODB\_SYS\_DATAFILES Table

The `INNODB_SYS_DATAFILES` table provides data file path information for `InnoDB` file-per-table and general tablespaces, equivalent to the information in the `SYS_DATAFILES` table in the `InnoDB` data dictionary.

For related usage information and examples, see [Section 14.16.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

#### Note

The `INFORMATION_SCHEMA FILES` table reports metadata for all `InnoDB` tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, the temporary tablespace, and undo tablespaces, if present.

The `INNODB_SYS_DATAFILES` table has these columns:

- **SPACE**

The tablespace ID.

- **PATH**

The tablespace data file path. If a [file-per-table](#) tablespace is created in a location outside the MySQL data directory, the path value is a fully qualified directory path. Otherwise, the path is relative to the data directory.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_DATAFILES WHERE SPACE = 57\G
***** 1. row *****
SPACE: 57
PATH: ./test/t1.ibd
```

## Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION\\_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

## 24.4.19 The INFORMATION\_SCHEMA INNODB\_SYS\_FIELDS Table

The [INNODB\\_SYS\\_FIELDS](#) table provides metadata about the key columns (fields) of [InnoDB](#) indexes, equivalent to the information from the [SYS\\_FIELDS](#) table in the [InnoDB](#) data dictionary.

For related usage information and examples, see [Section 14.16.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

The [INNODB\\_SYS\\_FIELDS](#) table has these columns:

- **INDEX\_ID**

An identifier for the index associated with this key field; the same value as [INNODB\\_SYS\\_INDEXES.INDEX\\_ID](#).

- **NAME**

The name of the original column from the table; the same value as [INNODB\\_SYS\\_COLUMNS.NAME](#).

- **POS**

The ordinal position of the key field within the index, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FIELDS WHERE INDEX_ID = 117\G
***** 1. row *****
INDEX_ID: 117
NAME: col1
POS: 0
```

## Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION\\_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

## 24.4.20 The INFORMATION\_SCHEMA INNODB\_SYS\_FOREIGN Table

The `INNODB_SYS_FOREIGN` table provides metadata about InnoDB foreign keys, equivalent to the information from the `SYS_FOREIGN` table in the InnoDB data dictionary.

For related usage information and examples, see [Section 14.16.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

The `INNODB_SYS_FOREIGN` table has these columns:

- `ID`

The name (not a numeric value) of the foreign key index, preceded by the schema (database) name (for example, `test/products_fk`).

- `FOR_NAME`

The name of the `child table` in this foreign key relationship.

- `REF_NAME`

The name of the `parent table` in this foreign key relationship.

- `N_COLS`

The number of columns in the foreign key index.

- `TYPE`

A collection of bit flags with information about the foreign key column, ORed together. 0 = `ON DELETE/UPDATE RESTRICT`, 1 = `ON DELETE CASCADE`, 2 = `ON DELETE SET NULL`, 4 = `ON UPDATE CASCADE`, 8 = `ON UPDATE SET NULL`, 16 = `ON DELETE NO ACTION`, 32 = `ON UPDATE NO ACTION`.

### Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN\G
***** 1. row *****
 ID: test/fk1
FOR_NAME: test/child
REF_NAME: test/parent
 N_COLS: 1
 TYPE: 1
```

### Notes

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

## 24.4.21 The INFORMATION\_SCHEMA INNODB\_SYS\_FOREIGN\_COLS Table

The `INNODB_SYS_FOREIGN_COLS` table provides status information about the columns of InnoDB foreign keys, equivalent to the information from the `SYS_FOREIGN_COLS` table in the InnoDB data dictionary.

For related usage information and examples, see [Section 14.16.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

The `INNODB_SYS_FOREIGN_COLS` table has these columns:

- `ID`

The foreign key index associated with this index key field, using the same value as `INNODB_SYS_FOREIGN.ID`.

- `FOR_COL_NAME`

The name of the associated column in the child table.

- `REF_COL_NAME`

The name of the associated column in the parent table.

- `POS`

The ordinal position of this key field within the foreign key index, starting from 0.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS WHERE ID = 'test/fk1'\G
***** 1. row *****
ID: test/fk1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
POS: 0
```

## Notes

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

## 24.4.22 The INFORMATION\_SCHEMA INNODB\_SYS\_INDEXES Table

The `INNODB_SYS_INDEXES` table provides metadata about `InnoDB` indexes, equivalent to the information in the internal `SYS_INDEXES` table in the `InnoDB` data dictionary.

For related usage information and examples, see [Section 14.16.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

The `INNODB_SYS_INDEXES` table has these columns:

- `INDEX_ID`

An identifier for the index. Index identifiers are unique across all the databases in an instance.

- `NAME`

The name of the index. Most indexes created implicitly by `InnoDB` have consistent names but the index names are not necessarily unique. Examples: `PRIMARY` for a primary key index, `GEN_CLUST_INDEX` for the index representing a primary key when one is not specified, and `ID_IND`, `FOR_IND`, and `REF_IND` for foreign key constraints.

- `TABLE_ID`

An identifier representing the table associated with the index; the same value as `INNODB_SYS_TABLES.TABLE_ID`.

- `TYPE`

A numeric value derived from bit-level information that identifies the index type. 0 = nonunique secondary index; 1 = automatically generated clustered index (`GEN_CLUST_INDEX`); 2 = unique nonclustered index; 3 = clustered index; 32 = full-text index; 64 = spatial index; 128 = secondary index on a `virtual generated column`.

- [N\\_FIELDS](#)

The number of columns in the index key. For [GEN\\_CLUST\\_INDEX](#) indexes, this value is 0 because the index is created using an artificial value rather than a real table column.

- [PAGE\\_NO](#)

The root page number of the index B-tree. For full-text indexes, the [PAGE\\_NO](#) column is unused and set to -1 ([FILE\\_NULL](#)) because the full-text index is laid out in several B-trees (auxiliary tables).

- [SPACE](#)

An identifier for the tablespace where the index resides. 0 means the [InnoDB system tablespace](#). Any other number represents a table created with a separate [.ibd](#) file in [file-per-table](#) mode. This identifier stays the same after a [TRUNCATE TABLE](#) statement. Because all indexes for a table reside in the same tablespace as the table, this value is not necessarily unique.

- [MERGE\\_THRESHOLD](#)

The merge threshold value for index pages. If the amount of data in an index page falls below the [MERGE\\_THRESHOLD](#) value when a row is deleted or when a row is shortened by an update operation, [InnoDB](#) attempts to merge the index page with the neighboring index page. The default threshold value is 50%. For more information, see [Section 14.8.12, “Configuring the Merge Threshold for Index Pages”](#).

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE TABLE_ID = 34\G
***** 1. row *****
 INDEX_ID: 39
 NAME: GEN_CLUST_INDEX
 TABLE_ID: 34
 TYPE: 1
 N_FIELDS: 0
 PAGE_NO: 3
 SPACE: 23
MERGE_THRESHOLD: 50
***** 2. row *****
 INDEX_ID: 40
 NAME: i1
 TABLE_ID: 34
 TYPE: 0
 N_FIELDS: 1
 PAGE_NO: 4
 SPACE: 23
MERGE_THRESHOLD: 50
```

## Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION\\_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

## 24.4.23 The INFORMATION\_SCHEMA INNODB\_SYS\_TABLES Table

The [INNODB\\_SYS\\_TABLES](#) table provides metadata about [InnoDB](#) tables, equivalent to the information from the [SYS\\_TABLES](#) table in the [InnoDB](#) data dictionary.

For related usage information and examples, see [Section 14.16.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

The [INNODB\\_SYS\\_TABLES](#) table has these columns:

- **TABLE\_ID**

An identifier for the [InnoDB](#) table. This value is unique across all databases in the instance.

- **NAME**

The name of the table, preceded by the schema (database) name where appropriate (for example, `test/t1`). Names of databases and user tables are in the same case as they were originally defined, possibly influenced by the [lower\\_case\\_table\\_names](#) setting.

- **FLAG**

A numeric value that represents bit-level information about table format and storage characteristics.

- **N\_COLS**

The number of columns in the table. The number reported includes three hidden columns that are created by [InnoDB](#) (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`). The number reported also includes [virtual generated columns](#), if present.

- **SPACE**

An identifier for the tablespace where the table resides. 0 means the [InnoDB system tablespace](#). Any other number represents either a [file-per-table](#) tablespace or a general tablespace. This identifier stays the same after a [TRUNCATE TABLE](#) statement. For file-per-table tablespaces, this identifier is unique for tables across all databases in the instance.

- **FILE\_FORMAT**

The table's file format ([Antelope](#) or [Barracuda](#)).

- **ROW\_FORMAT**

The table's row format ([Compact](#), [Redundant](#), [Dynamic](#), or [Compressed](#)).

- **ZIP\_PAGE\_SIZE**

The zip page size. Applies only to tables with a row format of [Compressed](#).

- **SPACE\_TYPE**

The type of tablespace to which the table belongs. Possible values include [System](#) for the system tablespace, [General](#) for general tablespaces, and [Single](#) for file-per-table tablespaces. Tables assigned to the system tablespace using [CREATE TABLE](#) or [ALTER TABLE TABLESPACE=innodb\\_system](#) have a [SPACE\\_TYPE](#) of [General](#). For more information, see [CREATE TABLESPACE](#).

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE TABLE_ID = 214\G
***** 1. row *****
 TABLE_ID: 214
 NAME: test/t1
 FLAG: 129
 N_COLS: 4
 SPACE: 233
 FILE_FORMAT: Antelope
 ROW_FORMAT: Compact
 ZIP_PAGE_SIZE: 0
 SPACE_TYPE: General
```

## Notes

- You must have the [PROCESS](#) privilege to query this table.

- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

#### 24.4.24 The INFORMATION\_SCHEMA INNODB\_SYS\_TABLESPACES Table

The `INNODB_SYS_TABLESPACES` table provides metadata about `InnoDB` file-per-table and general tablespaces, equivalent to the information in the `SYS_TABLESPACES` table in the `InnoDB` data dictionary.

For related usage information and examples, see [Section 14.16.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

##### Note

The `INFORMATION_SCHEMA FILES` table reports metadata for all `InnoDB` tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, the temporary tablespace, and undo tablespaces, if present.

The `INNODB_SYS_TABLESPACES` table has these columns:

- `SPACE`

The tablespace ID.

- `NAME`

The schema (database) and table name.

- `FLAG`

A numeric value that represents bit-level information about tablespace format and storage characteristics.

- `FILE_FORMAT`

The tablespace file format. For example, `Antelope`, `Barracuda`, or `Any` ([general tablespaces](#) support any row format). The data in this field is interpreted from the tablespace flags information that resides in the `.ibd` file. For more information about `InnoDB` file formats, see [Section 14.10, “InnoDB File-Format Management”](#).

- `ROW_FORMAT`

The tablespace row format (`Compact` or `Redundant`, `Dynamic`, or `Compressed`). The data in this column is interpreted from the tablespace flags information that resides in the `.ibd` file.

- `PAGE_SIZE`

The tablespace page size. The data in this column is interpreted from the tablespace flags information that resides in the `.ibd` file.

- `ZIP_PAGE_SIZE`

The tablespace zip page size. The data in this column is interpreted from the tablespace flags information that resides in the `.ibd` file.

- `SPACE_TYPE`

The type of tablespace. Possible values include `General` for general tablespaces and `Single` for file-per-table tablespaces.

- `FS_BLOCK_SIZE`

The file system block size, which is the unit size used for hole punching. This column pertains to the [InnoDB transparent page compression](#) feature.

- [FILE\\_SIZE](#)

The apparent size of the file, which represents the maximum size of the file, uncompressed. This column pertains to the [InnoDB transparent page compression](#) feature.

- [ALLOCATED\\_SIZE](#)

The actual size of the file, which is the amount of space allocated on disk. This column pertains to the [InnoDB transparent page compression](#) feature.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE SPACE = 26\G
***** 1. row *****
 SPACE: 26
 NAME: test/t1
 FLAG: 0
FILE_FORMAT: Antelope
 ROW_FORMAT: Compact or Redundant
 PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0
 SPACE_TYPE: Single
FS_BLOCK_SIZE: 4096
 FILE_SIZE: 98304
ALLOCATED_SIZE: 65536
```

## Notes

- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION\\_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.
- Because tablespace flags are always zero for all Antelope file formats (unlike table flags), there is no way to determine from this flag integer if the tablespace row format is Redundant or Compact. As a result, the possible values for the [ROW\\_FORMAT](#) field are “Compact or Redundant”, “Compressed”, or “Dynamic.”
- With the introduction of general tablespaces, [InnoDB](#) system tablespace data (for SPACE 0) is exposed in [INNODB\\_SYS\\_TABLESPACES](#).

## 24.4.25 The INFORMATION\_SCHEMA INNODB\_SYS\_TABLESTATS View

The [INNODB\\_SYS\\_TABLESTATS](#) table provides a view of low-level status information about [InnoDB](#) tables. This data is used by the MySQL optimizer to calculate which index to use when querying an [InnoDB](#) table. This information is derived from in-memory data structures rather than data stored on disk. There is no corresponding internal [InnoDB](#) system table.

[InnoDB](#) tables are represented in this view if they have been opened since the last server restart and have not aged out of the table cache. Tables for which persistent stats are available are always represented in this view.

Table statistics are updated only for [DELETE](#) or [UPDATE](#) operations that modify indexed columns. Statistics are not updated by operations that modify only nonindexed columns.

[ANALYZE TABLE](#) clears table statistics and sets the [STATS\\_INITIALIZED](#) column to [Uninitialized](#). Statistics are collected again the next time the table is accessed.

For related usage information and examples, see [Section 14.16.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

The `INNODB_SYS_TABLESTATS` table has these columns:

- `TABLE_ID`

An identifier representing the table for which statistics are available; the same value as `INNODB_SYS_TABLES.TABLE_ID`.

- `NAME`

The name of the table; the same value as `INNODB_SYS_TABLES.NAME`.

- `STATS_INITIALIZED`

The value is `Initialized` if the statistics are already collected, `Uninitialized` if not.

- `NUM_ROWS`

The current estimated number of rows in the table. Updated after each DML operation. The value could be imprecise if uncommitted transactions are inserting into or deleting from the table.

- `CLUST_INDEX_SIZE`

The number of pages on disk that store the clustered index, which holds the InnoDB table data in primary key order. This value might be null if no statistics are collected yet for the table.

- `OTHER_INDEX_SIZE`

The number of pages on disk that store all secondary indexes for the table. This value might be null if no statistics are collected yet for the table.

- `MODIFIED_COUNTER`

The number of rows modified by DML operations, such as `INSERT`, `UPDATE`, `DELETE`, and also cascade operations from foreign keys. This column is reset each time table statistics are recalculated.

- `AUTOINC`

The next number to be issued for any auto-increment-based operation. The rate at which the `AUTOINC` value changes depends on how many times auto-increment numbers have been requested and how many numbers are granted per request.

- `REF_COUNT`

When this counter reaches zero, the table metadata can be evicted from the table cache.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS where TABLE_ID = 71\G
***** 1. row *****
 TABLE_ID: 71
 NAME: test/t1
STATS_INITIALIZED: Initialized
 NUM_ROWS: 1
CLUST_INDEX_SIZE: 1
OTHER_INDEX_SIZE: 0
MODIFIED_COUNTER: 1
 AUTOINC: 0
 REF_COUNT: 1
```

## Notes

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the `PROCESS` privilege to query this table.

- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

#### 24.4.26 The INFORMATION\_SCHEMA INNODB\_SYS\_VIRTUAL Table

The `INNODB_SYS_VIRTUAL` table provides metadata about `InnoDB virtual generated columns` and columns upon which virtual generated columns are based, equivalent to information in the `SYS_VIRTUAL` table in the `InnoDB` data dictionary.

A row appears in the `INNODB_SYS_VIRTUAL` table for each column upon which a virtual generated column is based.

The `INNODB_SYS_VIRTUAL` table has these columns:

- `TABLE_ID`

An identifier representing the table associated with the virtual column; the same value as `INNODB_SYS_TABLES.TABLE_ID`.

- `POS`

The position value of the `virtual generated column`. The value is large because it encodes the column sequence number and ordinal position. The formula used to calculate the value uses a bitwise operation:

```
((nth virtual generated column for the InnoDB instance + 1) << 16)
+ the ordinal position of the virtual generated column
```

For example, if the first virtual generated column in the `InnoDB` instance is the third column of the table, the formula is `(0 + 1) << 16` + 2. The first virtual generated column in the `InnoDB` instance is always number 0. As the third column in the table, the ordinal position of the virtual generated column is 2. Ordinal positions are counted from 0.

- `BASE_POS`

The ordinal position of the columns upon which a virtual generated column is based.

#### Example

```
mysql> CREATE TABLE `t1` (
 `a` int(11) DEFAULT NULL,
 `b` int(11) DEFAULT NULL,
 `c` int(11) GENERATED ALWAYS AS (a+b) VIRTUAL,
 `h` varchar(10) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_VIRTUAL
WHERE TABLE_ID IN
(SELECT TABLE_ID FROM INFORMATION_SCHEMA.INNODB_TABLES
WHERE NAME LIKE "test/t1");
+-----+-----+-----+
| TABLE_ID | POS | BASE_POS |
+-----+-----+-----+
| 95 | 65538 | 0 |
| 95 | 65538 | 1 |
+-----+-----+-----+
```

#### Notes

- If a constant value is assigned to a `virtual generated column`, as in the following table, an entry for the column does not appear in the `INNODB_SYS_VIRTUAL` table. For an entry to appear, a virtual generated column must have a base column.

```
CREATE TABLE `t1` (
`a` int(11) DEFAULT NULL,
```

```

`b` int(11) DEFAULT NULL,
`c` int(11) GENERATED ALWAYS AS (5) VIRTUAL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;

```

However, metadata for such a column does appear in the `INNODB_SYS_COLUMNS` table.

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

## 24.4.27 The INFORMATION\_SCHEMA INNODB\_TEMP\_TABLE\_INFO Table

The `INNODB_TEMP_TABLE_INFO` table provides information about user-created InnoDB temporary tables that are active in an InnoDB instance. It does not provide information about internal InnoDB temporary tables used by the optimizer. The `INNODB_TEMP_TABLE_INFO` table is created when first queried, exists only in memory, and is not persisted to disk.

For usage information and examples, see [Section 14.16.7, “InnoDB INFORMATION\\_SCHEMA Temporary Table Info Table”](#).

The `INNODB_TEMP_TABLE_INFO` table has these columns:

- `TABLE_ID`

The table ID of the temporary table.

- `NAME`

The name of the temporary table.

- `N_COLS`

The number of columns in the temporary table. The number includes three hidden columns created by InnoDB (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`).

- `SPACE`

The ID of the temporary tablespace where the temporary table resides. In 5.7, non-compressed InnoDB temporary tables reside in a shared temporary tablespace. The data file for the shared temporary tablespace is defined by the `innodb_temp_data_file_path` system variable. By default, there is a single data file for the shared temporary tablespace named `ibtmp1`, which is located in the data directory. Compressed temporary tables reside in separate file-per-table tablespaces located in the temporary file directory defined by `tmpdir`. The temporary tablespace ID is a nonzero value that is dynamically generated on server restart.

- `PER_TABLE_TABLESPACE`

A value of `TRUE` indicates that the temporary table resides in a separate file-per-table tablespace. A value of `FALSE` indicates that the temporary table resides in the shared temporary tablespace.

- `IS_COMPRESSED`

A value of `TRUE` indicates that the temporary table is compressed.

### Example

```

mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
 TABLE_ID: 38
 NAME: #sql126cf_6_0
 N_COLS: 4

```

```
SPACE: 52
PER_TABLE_TABLESPACE: FALSE
IS_COMPRESSED: FALSE
```

## Notes

- This table is useful primarily for expert-level monitoring.
- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION\\_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

### 24.4.28 The INFORMATION\_SCHEMA INNODB\_TRX Table

The [INNODB\\_TRX](#) table provides information about every transaction currently executing inside InnoDB, including whether the transaction is waiting for a lock, when the transaction started, and the SQL statement the transaction is executing, if any.

For usage information, see [Section 14.16.2.1, “Using InnoDB Transaction and Locking Information”](#).

The [INNODB\\_TRX](#) table has these columns:

- [TRX\\_ID](#)

A unique transaction ID number, internal to InnoDB. These IDs are not created for transactions that are read only and nonlocking. For details, see [Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”](#).

- [TRX\\_WEIGHT](#)

The weight of a transaction, reflecting (but not necessarily the exact count of) the number of rows altered and the number of rows locked by the transaction. To resolve a deadlock, InnoDB selects the transaction with the smallest weight as the “victim” to roll back. Transactions that have changed nontransactional tables are considered heavier than others, regardless of the number of altered and locked rows.

- [TRX\\_STATE](#)

The transaction execution state. Permitted values are [RUNNING](#), [LOCK\\_WAIT](#), [ROLLING\\_BACK](#), and [COMMITTING](#).

- [TRX\\_STARTED](#)

The transaction start time.

- [TRX\\_REQUESTED\\_LOCK\\_ID](#)

The ID of the lock the transaction is currently waiting for, if [TRX\\_STATE](#) is [LOCK\\_WAIT](#); otherwise [NULL](#). To obtain details about the lock, join this column with the [LOCK\\_ID](#) column of the [INNODB\\_LOCKS](#) table.

- [TRX\\_WAIT\\_STARTED](#)

The time when the transaction started waiting on the lock, if [TRX\\_STATE](#) is [LOCK\\_WAIT](#); otherwise [NULL](#).

- [TRX\\_MYSQL\\_THREAD\\_ID](#)

The MySQL thread ID. To obtain details about the thread, join this column with the [ID](#) column of the [INFORMATION\\_SCHEMA PROCESSLIST](#) table, but see [Section 14.16.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).

- [TRX\\_QUERY](#)

The SQL statement that is being executed by the transaction.
- [TRX\\_OPERATION\\_STATE](#)

The transaction's current operation, if any; otherwise `NULL`.
- [TRX\\_TABLES\\_IN\\_USE](#)

The number of `InnoDB` tables used while processing the current SQL statement of this transaction.
- [TRX\\_TABLES\\_LOCKED](#)

The number of `InnoDB` tables that the current SQL statement has row locks on. (Because these are row locks, not table locks, the tables can usually still be read from and written to by multiple transactions, despite some rows being locked.)
- [TRX\\_LOCK\\_STRUCTS](#)

The number of locks reserved by the transaction.
- [TRX\\_LOCK\\_MEMORY\\_BYTES](#)

The total size taken up by the lock structures of this transaction in memory.
- [TRX\\_ROWS\\_LOCKED](#)

The approximate number of rows locked by this transaction. The value might include delete-marked rows that are physically present but not visible to the transaction.
- [TRX\\_ROWS\\_MODIFIED](#)

The number of modified and inserted rows in this transaction.
- [TRX\\_CONCURRENCY\\_TICKETS](#)

A value indicating how much work the current transaction can do before being swapped out, as specified by the `innodb_concurrency_tickets` system variable.
- [TRX\\_ISOLATION\\_LEVEL](#)

The isolation level of the current transaction.
- [TRX\\_UNIQUE\\_CHECKS](#)

Whether unique checks are turned on or off for the current transaction. For example, they might be turned off during a bulk data load.
- [TRX\\_FOREIGN\\_KEY\\_CHECKS](#)

Whether foreign key checks are turned on or off for the current transaction. For example, they might be turned off during a bulk data load.
- [TRX\\_LAST\\_FOREIGN\\_KEY\\_ERROR](#)

The detailed error message for the last foreign key error, if any; otherwise `NULL`.
- [TRX\\_ADAPTIVE\\_HASH\\_LATCHED](#)

Whether the adaptive hash index is locked by the current transaction. When the adaptive hash index search system is partitioned, a single transaction does not lock the entire adaptive hash index. Adaptive hash index partitioning is controlled by `innodb_adaptive_hash_index_parts`, which is set to 8 by default.

- [TRX\\_ADAPTIVE\\_HASH\\_TIMEOUT](#)

Whether to relinquish the search latch immediately for the adaptive hash index, or reserve it across calls from MySQL. When there is no adaptive hash index contention, this value remains zero and statements reserve the latch until they finish. During times of contention, it counts down to zero, and statements release the latch immediately after each row lookup. When the adaptive hash index search system is partitioned (controlled by [innodb\\_adaptive\\_hash\\_index\\_parts](#)), the value remains 0.

- [TRX\\_IS\\_READ\\_ONLY](#)

A value of 1 indicates the transaction is read only.

- [TRX\\_AUTOCOMMIT\\_NON\\_LOCKING](#)

A value of 1 indicates the transaction is a [SELECT](#) statement that does not use the [FOR UPDATE](#) or [LOCK IN SHARED MODE](#) clauses, and is executing with [autocommit](#) enabled so that the transaction contains only this one statement. When this column and [TRX\\_IS\\_READ\\_ONLY](#) are both 1, InnoDB optimizes the transaction to reduce the overhead associated with transactions that change table data.

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TRX\G
***** 1. row *****
 trx_id: 1510
 trx_state: RUNNING
 trx_started: 2014-11-19 13:24:40
 trx_requested_lock_id: NULL
 trx_wait_started: NULL
 trx_weight: 586739
 trx_mysql_thread_id: 2
 trx_query: DELETE FROM employees.salaries WHERE salary > 65000
 trx_operation_state: updating or deleting
 trx_tables_in_use: 1
 trx_tables_locked: 1
 trx_lock_structs: 3003
 trx_lock_memory_bytes: 450768
 trx_rows_locked: 1407513
 trx_rows_modified: 583736
 trx_concurrency_tickets: 0
 trx_isolation_level: REPEATABLE READ
 trx_unique_checks: 1
 trx_foreign_key_checks: 1
 trx_last_foreign_key_error: NULL
 trx_adaptive_hash_latched: 0
 trx_adaptive_hash_timeout: 10000
 trx_is_read_only: 0
 trx_autocommit_non_locking: 0
```

## Notes

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in [Section 14.16.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).
- You must have the [PROCESS](#) privilege to query this table.
- Use the [INFORMATION\\_SCHEMA COLUMNS](#) table or the [SHOW COLUMNS](#) statement to view additional information about the columns of this table, including data types and default values.

## 24.5 INFORMATION\_SCHEMA Thread Pool Tables

The following sections describe the [INFORMATION\\_SCHEMA](#) tables associated with the thread pool plugin (see [Section 5.5.3, “MySQL Enterprise Thread Pool”](#)). They provide information about thread pool operation:

- [TP\\_THREAD\\_GROUP\\_STATE](#): Information about thread pool thread group states
- [TP\\_THREAD\\_GROUP\\_STATS](#): Thread group statistics
- [TP\\_THREAD\\_STATE](#): Information about thread pool thread states

Rows in these tables represent snapshots in time. In the case of [TP\\_THREAD\\_STATE](#), all rows for a thread group comprise a snapshot in time. Thus, the MySQL server holds the mutex of the thread group while producing the snapshot. But it does not hold mutexes on all thread groups at the same time, to prevent a statement against [TP\\_THREAD\\_STATE](#) from blocking the entire MySQL server.

The thread pool [INFORMATION\\_SCHEMA](#) tables are implemented by individual plugins and the decision whether to load one can be made independently of the others (see [Section 5.5.3.2, “Thread Pool Installation”](#)). However, the content of all the tables depends on the thread pool plugin being enabled. If a table plugin is enabled but the thread pool plugin is not, the table becomes visible and can be accessed, but is empty.

## 24.5.1 INFORMATION\_SCHEMA Thread Pool Table Reference

The following table summarizes [INFORMATION\\_SCHEMA](#) thread pool tables. For greater detail, see the individual table descriptions.

**Table 24.7 INFORMATION\_SCHEMA Thread Pool Tables**

| Name                                  | Description                         |
|---------------------------------------|-------------------------------------|
| <a href="#">TP_THREAD_GROUP_STATE</a> | Thread pool thread group states     |
| <a href="#">TP_THREAD_GROUP_STATS</a> | Thread pool thread group statistics |
| <a href="#">TP_THREAD_STATE</a>       | Thread pool thread information      |

## 24.5.2 The INFORMATION\_SCHEMA TP\_THREAD\_GROUP\_STATE Table

The [TP\\_THREAD\\_GROUP\\_STATE](#) table has one row per thread group in the thread pool. Each row provides information about the current state of a group.

The [TP\\_THREAD\\_GROUP\\_STATE](#) table has these columns:

- [TP\\_GROUP\\_ID](#)

The thread group ID. This is a unique key within the table.

- [CONSUMER\\_THREADS](#)

The number of consumer threads. There is at most one thread ready to start executing if the active threads become stalled or blocked.

- [RESERVE\\_THREADS](#)

The number of threads in the reserved state. This means that they are not started until there is a need to wake a new thread and there is no consumer thread. This is where most threads end up when the thread group has created more threads than needed for normal operation. Often a thread group needs additional threads for a short while and then does not need them again for a while. In this case, they go into the reserved state and remain until needed again. They take up some extra memory resources, but no extra computing resources.

- [CONNECT\\_THREAD\\_COUNT](#)

The number of threads that are processing or waiting to process connection initialization and authentication. There can be a maximum of four connection threads per thread group; these threads expire after a period of inactivity.

This column was added in MySQL 5.7.18.

- [CONNECTION\\_COUNT](#)

The number of connections using this thread group.

- [QUEUED\\_QUERIES](#)

The number of statements waiting in the high-priority queue.

- [QUEUED\\_TRANSACTIONS](#)

The number of statements waiting in the low-priority queue. These are the initial statements for transactions that have not started, so they also represent queued transactions.

- [STALL\\_LIMIT](#)

The value of the `thread_pool_stall_limit` system variable for the thread group. This is the same value for all thread groups.

- [PRIO\\_KICKUP\\_TIMER](#)

The value of the `thread_pool_prio_kickup_timer` system variable for the thread group. This is the same value for all thread groups.

- [ALGORITHM](#)

The value of the `thread_pool_algorithm` system variable for the thread group. This is the same value for all thread groups.

- [THREAD\\_COUNT](#)

The number of threads started in the thread pool as part of this thread group.

- [ACTIVE\\_THREAD\\_COUNT](#)

The number of threads active in executing statements.

- [STALLED\\_THREAD\\_COUNT](#)

The number of stalled statements in the thread group. A stalled statement could be executing, but from a thread pool perspective it is stalled and making no progress. A long-running statement quickly ends up in this category.

- [WAITING\\_THREAD\\_NUMBER](#)

If there is a thread handling the polling of statements in the thread group, this specifies the thread number within this thread group. It is possible that this thread could be executing a statement.

- [OLDEST\\_QUEUED](#)

How long in milliseconds the oldest queued statement has been waiting for execution.

- [MAX\\_THREAD\\_IDS\\_IN\\_GROUP](#)

The maximum thread ID of the threads in the group. This is the same as `MAX(TP_THREAD_NUMBER)` for the threads when selected from the `TP_THREAD_STATE` table. That is, these two queries are equivalent:

```
SELECT TP_GROUP_ID, MAX_THREAD_IDS_IN_GROUP
FROM TP_THREAD_GROUP_STATE;

SELECT TP_GROUP_ID, MAX(TP_THREAD_NUMBER)
```

```
FROM TP_THREAD_STATE GROUP BY TP_GROUP_ID;
```

## 24.5.3 The INFORMATION\_SCHEMA TP\_THREAD\_GROUP\_STATS Table

The `TP_THREAD_GROUP_STATS` table reports statistics per thread group. There is one row per group.

The `TP_THREAD_GROUP_STATS` table has these columns:

- `TP_GROUP_ID`

The thread group ID. This is a unique key within the table.

- `CONNECTIONS_STARTED`

The number of connections started.

- `CONNECTIONS_CLOSED`

The number of connections closed.

- `QUERIES_EXECUTED`

The number of statements executed. This number is incremented when a statement starts executing, not when it finishes.

- `QUERIES_QUEUED`

The number of statements received that were queued for execution. This does not count statements that the thread group was able to begin executing immediately without queuing, which can happen under the conditions described in [Section 5.5.3.3, “Thread Pool Operation”](#).

- `THREADS_STARTED`

The number of threads started.

- `PRIORITIES_KICKUPS`

The number of statements that have been moved from low-priority queue to high-priority queue based on the value of the `thread_pool_prio_kickup_timer` system variable. If this number increases quickly, consider increasing the value of that variable. A quickly increasing counter means that the priority system is not keeping transactions from starting too early. For `InnoDB`, this most likely means deteriorating performance due to too many concurrent transactions..

- `STALLED_QUERIES_EXECUTED`

The number of statements that have become defined as stalled due to executing for longer than the value of the `thread_pool_stall_limit` system variable.

- `BECOME_CONSUMER_THREAD`

The number of times threads have been assigned the consumer thread role.

- `BECOME_RESERVE_THREAD`

The number of times threads have been assigned the reserve thread role.

- `BECOME_WAITING_THREAD`

The number of times threads have been assigned the waiter thread role. When statements are queued, this happens very often, even in normal operation, so rapid increases in this value are normal in the case of a highly loaded system where statements are queued up.

- `WAKE_THREAD_STALL_CHECKER`

The number of times the stall check thread decided to wake or create a thread to possibly handle some statements or take care of the waiter thread role.

- [SLEEP\\_WAITS](#)

The number of `THD_WAIT_SLEEP` waits. These occur when threads go to sleep; for example, by calling the `SLEEP()` function.

- [DISK\\_IO\\_WAITS](#)

The number of `THD_WAIT_DISKIO` waits. These occur when threads perform disk I/O that is likely to not hit the file system cache. Such waits occur when the buffer pool reads and writes data to disk, not for normal reads from and writes to files.

- [ROW\\_LOCK\\_WAITS](#)

The number of `THD_WAIT_ROW_LOCK` waits for release of a row lock by another transaction.

- [GLOBAL\\_LOCK\\_WAITS](#)

The number of `THD_WAIT_GLOBAL_LOCK` waits for a global lock to be released.

- [META\\_DATA\\_LOCK\\_WAITS](#)

The number of `THD_WAIT_META_DATA_LOCK` waits for a metadata lock to be released.

- [TABLE\\_LOCK\\_WAITS](#)

The number of `THD_WAIT_TABLE_LOCK` waits for a table to be unlocked that the statement needs to access.

- [USER\\_LOCK\\_WAITS](#)

The number of `THD_WAIT_USER_LOCK` waits for a special lock constructed by the user thread.

- [BINLOG\\_WAITS](#)

The number of `THD_WAIT_BINLOG_WAITS` waits for the binary log to become free.

- [GROUP\\_COMMIT\\_WAITS](#)

The number of `THD_WAIT_GROUP_COMMIT` waits. These occur when a group commit must wait for the other parties to complete their part of a transaction.

- [FSYNC\\_WAITS](#)

The number of `THD_WAIT_SYNC` waits for a file sync operation.

#### 24.5.4 The INFORMATION\_SCHEMA TP\_THREAD\_STATE Table

The `TP_THREAD_STATE` table has one row per thread created by the thread pool to handle connections.

The `TP_THREAD_STATE` table has these columns:

- [TP\\_GROUP\\_ID](#)

The thread group ID.

- [TP\\_THREAD\\_NUMBER](#)

The ID of the thread within its thread group. `TP_GROUP_ID` and `TP_THREAD_NUMBER` together provide a unique key within the table.

- `PROCESS_COUNT`

The 10ms interval in which the statement that uses this thread is currently executing. 0 means no statement is executing, 1 means it is in the first 10ms, and so forth.

- `WAIT_TYPE`

The type of wait for the thread. `NULL` means the thread is not blocked. Otherwise, the thread is blocked by a call to `thd_wait_begin()` and the value specifies the type of wait. The `xxx_WAIT` columns of the `TP_THREAD_GROUP_STATS` table accumulate counts for each wait type.

The `WAIT_TYPE` value is a string that describes the type of wait, as shown in the following table.

**Table 24.8 TP\_THREAD\_STATE Table WAIT\_TYPE Values**

| Wait Type                            | Meaning                   |
|--------------------------------------|---------------------------|
| <code>THD_WAIT_SLEEP</code>          | Waiting for sleep         |
| <code>THD_WAIT_DISKIO</code>         | Waiting for Disk IO       |
| <code>THD_WAIT_ROW_LOCK</code>       | Waiting for row lock      |
| <code>THD_WAIT_GLOBAL_LOCK</code>    | Waiting for global lock   |
| <code>THD_WAIT_META_DATA_LOCK</code> | Waiting for metadata lock |
| <code>THD_WAIT_TABLE_LOCK</code>     | Waiting for table lock    |
| <code>THD_WAIT_USER_LOCK</code>      | Waiting for user lock     |
| <code>THD_WAIT_BINLOG</code>         | Waiting for binlog        |
| <code>THD_WAIT_GROUP_COMMIT</code>   | Waiting for group commit  |
| <code>THD_WAIT_SYNC</code>           | Waiting for fsync         |

## 24.6 INFORMATION\_SCHEMA Connection-Control Tables

The following sections describe the `INFORMATION_SCHEMA` tables associated with the `CONNECTION_CONTROL` plugin.

### 24.6.1 INFORMATION\_SCHEMA Connection-Control Table Reference

The following table summarizes `INFORMATION_SCHEMA` connection-control tables. For greater detail, see the individual table descriptions.

**Table 24.9 INFORMATION\_SCHEMA Connection-Control Tables**

| Name                            | Description                                                                       | Introduced |
|---------------------------------|-----------------------------------------------------------------------------------|------------|
| <code>CONNECTION_CONTROL</code> | <code>Current_number_of_Consecutive_failed_connection_attempts_per_account</code> | 5.7.17     |

### 24.6.2 The INFORMATION\_SCHEMA CONNECTION\_CONTROL\_FAILED\_LOGIN\_ATTEMPTS Table

This table provides information about the current number of consecutive failed connection attempts per account (user/host combination). The table was added in MySQL 5.7.17.

`CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` has these columns:

- `USERHOST`

The user/host combination indicating an account that has failed connection attempts, in `'user_name'@'host_name'` format.

- [FAILED\\_ATTEMPTS](#)

The current number of consecutive failed connection attempts for the [USERHOST](#) value. This counts all failed attempts, regardless of whether they were delayed. The number of attempts for which the server added a delay to its response is the difference between the [FAILED\\_ATTEMPTS](#) value and the [connection\\_control\\_failed\\_connections\\_threshold](#) system variable value.

## Notes

- The [CONNECTION\\_CONTROL\\_FAILED\\_LOGIN\\_ATTEMPTS](#) plugin must be activated for this table to be available, and the [CONNECTION\\_CONTROL](#) plugin must be activated or the table contents are always empty. See [Section 6.4.2, “The Connection-Control Plugins”](#).
- The table contains rows only for accounts that have had one or more consecutive failed connection attempts without a subsequent successful attempt. When an account connects successfully, its failed-connection count is reset to zero and the server removes any row corresponding to the account.
- Assigning a value to the [connection\\_control\\_failed\\_connections\\_threshold](#) system variable at runtime resets all accumulated failed-connection counters to zero, which causes the table to become empty.

## 24.7 INFORMATION\_SCHEMA MySQL Enterprise Firewall Tables

The following sections describe the [INFORMATION\\_SCHEMA](#) tables associated with MySQL Enterprise Firewall (see [Section 6.4.6, “MySQL Enterprise Firewall”](#)). They provide views into the firewall in-memory data cache. These tables are available only if the appropriate firewall plugins are enabled.

### 24.7.1 INFORMATION\_SCHEMA Firewall Table Reference

The following table summarizes [INFORMATION\\_SCHEMA](#) firewall tables. For greater detail, see the individual table descriptions.

**Table 24.10 INFORMATION\_SCHEMA Firewall Tables**

| Name                                     | Description                                            |
|------------------------------------------|--------------------------------------------------------|
| <a href="#">MYSQL_FIREWALL_USERS</a>     | Firewall in-memory data for account profiles           |
| <a href="#">MYSQL_FIREWALL_WHITELIST</a> | Firewall in-memory data for account profile allowlists |

### 24.7.2 The INFORMATION\_SCHEMA MYSQL\_FIREWALL\_USERS Table

The [MYSQL\\_FIREWALL\\_USERS](#) table provides a view into the in-memory data cache for MySQL Enterprise Firewall. It lists names and operational modes of registered firewall account profiles. It is used in conjunction with the [mysql.firewall\\_users](#) system table that provides persistent storage of firewall data; see [MySQL Enterprise Firewall Tables](#).

The [MYSQL\\_FIREWALL\\_USERS](#) table has these columns:

- [USERHOST](#)

The account profile name. Each account name has the format [user\\_name@host\\_name](#).

- [MODE](#)

The current operational mode for the profile. Permitted mode values are [OFF](#), [DETECTING](#), [PROTECTING](#), [RECORDING](#), and [RESET](#). For details about their meanings, see [Firewall Concepts](#).

### 24.7.3 The INFORMATION\_SCHEMA MYSQL\_FIREWALL\_WHITELIST Table

The `MYSQL_FIREWALL_WHITELIST` table provides a view into the in-memory data cache for MySQL Enterprise Firewall. It lists allowlist rules of registered firewall account profiles. It is used in conjunction with the `mysql.firewall_whitelist` system table that provides persistent storage of firewall data; see [MySQL Enterprise Firewall Tables](#).

The `MYSQL_FIREWALL_WHITELIST` table has these columns:

- `USERHOST`

The account profile name. Each account name has the format `user_name@host_name`.

- `RULE`

A normalized statement indicating an acceptable statement pattern for the profile. A profile allowlist is the union of its rules.

## 24.8 Extensions to SHOW Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- `SHOW` can be used to get information about the structure of `INFORMATION_SCHEMA` itself.
- Several `SHOW` statements accept a `WHERE` clause that provides more flexibility in specifying which rows to display.

The `IS_UPDATABLE` flag may be unreliable if a view depends on one or more other views, and one of these underlying views is updated. Regardless of the `IS_UPDATABLE` value, the server keeps track of the updatability of a view and correctly rejects data change operations to views that are not updatable. If the `IS_UPDATABLE` value for a view has become inaccurate due to changes to underlying views, the value can be updated by deleting and recreating the view.

`INFORMATION_SCHEMA` is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+-----+
| Tables_in_INFORMATION_SCHEMA |
+-----+
| CHARACTER_SETS
| COLLATIONS
| COLLATION_CHARACTER_SET_APPLICABILITY
| COLUMNS
| COLUMN_PRIVILEGES
| ENGINES
| EVENTS
| FILES
| GLOBAL_STATUS
| GLOBAL_VARIABLES
| KEY_COLUMN_USAGE
| PARTITIONS
| PLUGINS
| PROCESSLIST
| REFERENTIAL_CONSTRAINTS
| ROUTINES
| SCHEMATA
| SCHEMA_PRIVILEGES
| SESSION_STATUS
| SESSION_VARIABLES
| STATISTICS
| TABLES
| TABLE_CONSTRAINTS
| TABLE_PRIVILEGES
| TRIGGERS
| USER_PRIVILEGES
| VIEWS
```

```
+-----+
```

`SHOW COLUMNS` and `DESCRIBE` can display information about the columns in individual `INFORMATION_SCHEMA` tables.

`SHOW` statements that accept a `LIKE` clause to limit the rows displayed also permit a `WHERE` clause that specifies more general conditions that selected rows must satisfy:

```
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES
```

The `WHERE` clause, if present, is evaluated against the column names displayed by the `SHOW` statement. For example, the `SHOW CHARACTER SET` statement produces these output columns:

```
mysql> SHOW CHARACTER SET;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5 | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| dec8 | DEC West European | dec8_swedish_ci | 1 |
| cp850 | DOS West European | cp850_general_ci | 1 |
| hp8 | HP West European | hp8_english_ci | 1 |
| koi8r | KOI8-R Relcom Russian | koi8r_general_ci | 1 |
| latin1 | cp1252 West European | latin1_swedish_ci | 1 |
| latin2 | ISO 8859-2 Central European | latin2_general_ci | 1 |
...

```

To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string '`japanese`':

```
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| ujis | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| cp932 | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpm | UJIS for Windows Japanese | eucjpm_japanese_ci | 3 |

```

This statement displays the multibyte character sets:

```
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5 | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| ujis | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| euckr | EUC-KR Korean | euckr_korean_ci | 2 |
| gb2312 | GB2312 Simplified Chinese | gb2312_chinese_ci | 2 |
| gbk | GBK Simplified Chinese | gbk_chinese_ci | 2 |
| utf8 | UTF-8 Unicode | utf8_general_ci | 3 |
| ucs2 | UCS-2 Unicode | ucs2_general_ci | 2 |
| cp932 | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpm | UJIS for Windows Japanese | eucjpm_japanese_ci | 3 |

```

---

# Chapter 25 MySQL Performance Schema

## Table of Contents

The MySQL Performance Schema is a feature for monitoring MySQL Server execution at a low level. The Performance Schema has these characteristics:

- 
- The Performance Schema provides a way to inspect internal execution of the server at runtime. It is implemented using the `PERFORMANCE_SCHEMA` storage engine and the `performance_schema` database. The Performance Schema focuses primarily on performance data. This differs from `INFORMATION_SCHEMA`, which serves for inspection of metadata.
  - The Performance Schema monitors server events. An “event” is anything the server does that takes time and has been instrumented so that timing information can be collected. In general, an event could be a function call, a wait for the operating system, a stage of an SQL statement execution such as parsing or sorting, or an entire statement or group of statements. Event collection provides access to information about synchronization calls (such as for mutexes) file and table I/O, table locks, and so forth for the server and for several storage engines.
  - Performance Schema events are distinct from events written to the server's binary log (which describe data modifications) and Event Scheduler events (which are a type of stored program).
  - Performance Schema events are specific to a given instance of the MySQL Server. Performance Schema tables are considered local to the server, and changes to them are not replicated or written to the binary log.
  - Current events are available, as well as event histories and summaries. This enables you to determine how many times instrumented activities were performed and how much time they took. Event information is available to show the activities of specific threads, or activity associated with particular objects such as a mutex or file.
  - The `PERFORMANCE_SCHEMA` storage engine collects event data using “instrumentation points” in server source code.
  - Collected events are stored in tables in the `performance_schema` database. These tables can be queried using `SELECT` statements like other tables.
  - Performance Schema configuration can be modified dynamically by updating tables in the `performance_schema` database through SQL statements. Configuration changes affect data collection immediately.
  - Tables in the Performance Schema are in-memory tables that use no persistent on-disk storage. The contents are repopulated beginning at server startup and discarded at server shutdown.
  - Monitoring is available on all platforms supported by MySQL.

Some limitations might apply: The types of timers might vary per platform. Instruments that apply to storage engines might not be implemented for all storage engines. Instrumentation of each third-party engine is the responsibility of the engine maintainer. See also [Section 25.21, “Restrictions on Performance Schema”](#).

- Data collection is implemented by modifying the server source code to add instrumentation. There are no separate threads associated with the Performance Schema, unlike other features such as replication or the Event Scheduler.

The Performance Schema is intended to provide access to useful information about server execution while having minimal impact on server performance. The implementation follows these design goals:

- Activating the Performance Schema causes no changes in server behavior. For example, it does not cause thread scheduling to change, and it does not cause query execution plans (as shown by `EXPLAIN`) to change.
- Server monitoring occurs continuously and unobtrusively with very little overhead. Activating the Performance Schema does not make the server unusable.
- The parser is unchanged. There are no new keywords or statements.
- Execution of server code proceeds normally even if the Performance Schema fails internally.

- When there is a choice between performing processing during event collection initially or during event retrieval later, priority is given to making collection faster. This is because collection is ongoing whereas retrieval is on demand and might never happen at all.
- It is easy to add new instrumentation points.
- Instrumentation is versioned. If the instrumentation implementation changes, previously instrumented code continues to work. This benefits developers of third-party plugins because it is not necessary to upgrade each plugin to stay synchronized with the latest Performance Schema changes.

**Note**

The MySQL `sys` schema is a set of objects that provides convenient access to data collected by the Performance Schema. The `sys` schema is installed by default. For usage instructions, see [Chapter 26, MySQL sys Schema](#).

## 25.1 Performance Schema Quick Start

This section briefly introduces the Performance Schema with examples that show how to use it. For additional examples, see [Section 25.19, “Using the Performance Schema to Diagnose Problems”](#).

The Performance Schema is enabled by default. To enable or disable it explicitly, start the server with the `performance_schema` variable set to an appropriate value. For example, use these lines in the server `my.cnf` file:

```
[mysqld]
performance_schema=ON
```

When the server starts, it sees `performance_schema` and attempts to initialize the Performance Schema. To verify successful initialization, use this statement:

```
mysql> SHOW VARIABLES LIKE 'performance_schema';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| performance_schema | ON |
+-----+-----+
```

A value of `ON` means that the Performance Schema initialized successfully and is ready for use. A value of `OFF` means that some error occurred. Check the server error log for information about what went wrong.

The Performance Schema is implemented as a storage engine. If this engine is available (which you should already have checked earlier), you should see it listed with a `SUPPORT` value of `YES` in the output from the `INFORMATION_SCHEMA.ENGINES` table or the `SHOW ENGINES` statement:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.ENGINES
 WHERE ENGINE='PERFORMANCE_SCHEMA'\G
***** 1. row *****
 ENGINE: PERFORMANCE_SCHEMA
 SUPPORT: YES
 COMMENT: Performance Schema
TRANSACTIONS: NO
 XA: NO
 SAVEPOINTS: NO

mysql> SHOW ENGINES\G
...
 Engine: PERFORMANCE_SCHEMA
 Support: YES
 Comment: Performance Schema
Transactions: NO
 XA: NO
 Savepoints: NO
...
```

The `PERFORMANCE_SCHEMA` storage engine operates on tables in the `performance_schema` database. You can make `performance_schema` the default database so that references to its tables need not be qualified with the database name:

```
mysql> USE performance_schema;
```

Performance Schema tables are stored in the `performance_schema` database. Information about the structure of this database and its tables can be obtained, as for any other database, by selecting from the `INFORMATION_SCHEMA` database or by using `SHOW` statements. For example, use either of these statements to see what Performance Schema tables exist:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
 WHERE TABLE_SCHEMA = 'performance_schema';
+-----+
| TABLE_NAME
+-----+
| accounts
| cond_instances
...
| events_stages_current
| events_stages_history
| events_stages_history_long
| events_stages_summary_by_account_by_event_name
| events_stages_summary_by_host_by_event_name
| events_stages_summary_by_thread_by_event_name
| events_stages_summary_by_user_by_event_name
| events_stages_summary_global_by_event_name
| events_statements_current
| events_statements_history
| events_statements_history_long
...
| file_instances
| file_summary_by_event_name
| file_summary_by_instance
| host_cache
| hosts
| memory_summary_by_account_by_event_name
| memory_summary_by_host_by_event_name
| memory_summary_by_thread_by_event_name
| memory_summary_by_user_by_event_name
| memory_summary_global_by_event_name
| metadata_locks
| mutex_instances
| objects_summary_global_by_type
| performance_timers
| replication_connection_configuration
| replication_connection_status
| replication_applier_configuration
| replication_applier_status
| replication_applier_status_by_coordinator
| replication_applier_status_by_worker
| rwlock_instances
| session_account_connect_attrs
| session_connect_attrs
| setup_actors
| setup_consumers
| setup_instruments
| setup_objects
| setup_timers
| socket_instances
| socket_summary_by_event_name
| socket_summary_by_instance
| table_handles
| table_io_waits_summary_by_index_usage
| table_io_waits_summary_by_table
| table_lock_waits_summary_by_table
| threads
| users
+-----+
mysql> SHOW TABLES FROM performance_schema;
```

```
+-----+
| Tables_in_performance_schema |
+-----+
| accounts
| cond_instances
| events_stages_current
| events_stages_history
| events_stages_history_long
...

```

The number of Performance Schema tables increases over time as implementation of additional instrumentation proceeds.

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

To see the structure of individual tables, use `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE performance_schema.setup_consumers\G
***** 1. row *****
 Table: setup_consumers
Create Table: CREATE TABLE `setup_consumers` (
 `NAME` varchar(64) NOT NULL,
 `ENABLED` enum('YES','NO') NOT NULL
) ENGINE=PERFORMANCE_SCHEMA DEFAULT CHARSET=utf8
```

Table structure is also available by selecting from tables such as `INFORMATION_SCHEMA.COLUMNS` or by using statements such as `SHOW COLUMNS`.

Tables in the `performance_schema` database can be grouped according to the type of information in them: Current events, event histories and summaries, object instances, and setup (configuration) information. The following examples illustrate a few uses for these tables. For detailed information about the tables in each group, see [Section 25.12, “Performance Schema Table Descriptions”](#).

Initially, not all instruments and consumers are enabled, so the performance schema does not collect all events. To turn all of these on and enable event timing, execute two statements (the row counts may differ depending on MySQL version):

```
mysql> UPDATE performance_schema.setup_instruments
 SET ENABLED = 'YES', TIMED = 'YES';
Query OK, 560 rows affected (0.04 sec)
mysql> UPDATE performance_schema.setup_consumers
 SET ENABLED = 'YES';
Query OK, 10 rows affected (0.00 sec)
```

To see what the server is doing at the moment, examine the `events_waits_current` table. It contains one row per thread showing each thread's most recent monitored event:

```
mysql> SELECT *
 FROM performance_schema.events_waits_current\G
***** 1. row *****
 THREAD_ID: 0
 EVENT_ID: 5523
 END_EVENT_ID: 5523
 EVENT_NAME: wait/synch/mutex/mysys/THR_LOCK::mutex
 SOURCE: thr_lock.c:525
 TIMER_START: 201660494489586
 TIMER_END: 201660494576112
 TIMER_WAIT: 86526
 SPINS: NULL
 OBJECT_SCHEMA: NULL
 OBJECT_NAME: NULL
 INDEX_NAME: NULL
 OBJECT_TYPE: NULL
OBJECT_INSTANCE_BEGIN: 142270668
 NESTING_EVENT_ID: NULL
NESTING_EVENT_TYPE: NULL
 OPERATION: lock
 NUMBER_OF_BYTES: NULL
 FLAGS: 0
```

...

This event indicates that thread 0 was waiting for 86,526 picoseconds to acquire a lock on `THR_LOCK::mutex`, a mutex in the `mysys` subsystem. The first few columns provide the following information:

- The ID columns indicate which thread the event comes from and the event number.
- `EVENT_NAME` indicates what was instrumented and `SOURCE` indicates which source file contains the instrumented code.
- The timer columns show when the event started and stopped and how long it took. If an event is still in progress, the `TIMER_END` and `TIMER_WAIT` values are `NULL`. Timer values are approximate and expressed in picoseconds. For information about timers and event time collection, see [Section 25.4.1, “Performance Schema Event Timing”](#).

The history tables contain the same kind of rows as the current-events table but have more rows and show what the server has been doing “recently” rather than “currently.” The `events_waits_history` and `events_waits_history_long` tables contain the most recent 10 events per thread and most recent 10,000 events, respectively. For example, to see information for recent events produced by thread 13, do this:

```
mysql> SELECT EVENT_ID, EVENT_NAME, TIMER_WAIT
 FROM performance_schema.events_waits_history
 WHERE THREAD_ID = 13
 ORDER BY EVENT_ID;
+-----+-----+-----+
| EVENT_ID | EVENT_NAME | TIMER_WAIT |
+-----+-----+-----+
| 86 | wait/synch/mutex/my... | 686322 |
| 87 | wait/synch/mutex/my... | 320535 |
| 88 | wait/synch/mutex/my... | 339390 |
| 89 | wait/synch/mutex/my... | 377100 |
| 90 | wait/synch/mutex/sql... | 614673 |
| 91 | wait/synch/mutex/sql... | 659925 |
| 92 | wait/synch/mutex/sql... | 494001 |
| 93 | wait/synch/mutex/my... | 222489 |
| 94 | wait/synch/mutex/my... | 214947 |
| 95 | wait/synch/mutex/my... | 312993 |
+-----+-----+-----+
```

As new events are added to a history table, older events are discarded if the table is full.

Summary tables provide aggregated information for all events over time. The tables in this group summarize event data in different ways. To see which instruments have been executed the most times or have taken the most wait time, sort the `events_waits_summary_global_by_event_name` table on the `COUNT_STAR` or `SUM_TIMER_WAIT` column, which correspond to a `COUNT(*)` or `SUM(TIMER_WAIT)` value, respectively, calculated over all events:

```
mysql> SELECT EVENT_NAME, COUNT_STAR
 FROM performance_schema.events_waits_summary_global_by_event_name
 ORDER BY COUNT_STAR DESC LIMIT 10;
+-----+-----+
| EVENT_NAME | COUNT_STAR |
+-----+-----+
| wait/synch/mutex/my... | 6419 |
| wait/io/file/sql/FRM | 452 |
| wait/synch/mutex/sql/LOCK_plugin | 337 |
| wait/synch/mutex/my... | 187 |
| wait/synch/mutex/my... | 147 |
| wait/synch/mutex/sql/THD::LOCK_thd_data | 115 |
| wait/io/file/myisam/kfile | 102 |
| wait/synch/mutex/sql/LOCK_global_system_variables | 89 |
| wait/synch/mutex/my... | 89 |
| wait/synch/mutex/sql/LOCK_open | 88 |
+-----+-----+
mysql> SELECT EVENT_NAME, SUM_TIMER_WAIT
```

| EVENT_NAME                             | SUM_TIMER_WAIT |
|----------------------------------------|----------------|
| wait/io/file/sql/MYSQL_LOG             | 1599816582     |
| wait/synch/mutex/mysys/THR_LOCK_malloc | 1530083250     |
| wait/io/file/sql/binlog_index          | 1385291934     |
| wait/io/file/sql/FRM                   | 1292823243     |
| wait/io/file/myisam/kfile              | 411193611      |
| wait/io/file/myisam/dfile              | 322401645      |
| wait/synch/mutex/mysys/LOCK_alarm      | 145126935      |
| wait/io/file/sql/casetest              | 104324715      |
| wait/synch/mutex/sql/LOCK_plugin       | 86027823       |
| wait/io/file/sql/pid                   | 72591750       |

These results show that the `THR_LOCK_malloc` mutex is “hot,” both in terms of how often it is used and amount of time that threads wait attempting to acquire it.

### Note

The `THR_LOCK_malloc` mutex is used only in debug builds. In production builds it is not hot because it is nonexistent.

Instance tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information. For example, the `file_instances` table lists instances of instruments for file I/O operations and their associated files:

```
mysql> SELECT *
 FROM performance_schema.file_instances\G
***** 1. row *****
FILE_NAME: /opt/mysql-log/60500/binlog.000007
EVENT_NAME: wait/io/file/sql/binlog
OPEN_COUNT: 0
***** 2. row *****
FILE_NAME: /opt/mysql/60500/data/mysql/tables_priv.MYI
EVENT_NAME: wait/io/file/myisam/kfile
OPEN_COUNT: 1
***** 3. row *****
FILE_NAME: /opt/mysql/60500/data/mysql/columns_priv.MYI
EVENT_NAME: wait/io/file/myisam/kfile
OPEN_COUNT: 1
...
```

Setup tables are used to configure and display monitoring characteristics. For example, `setup_instruments` lists the set of instruments for which events can be collected and shows which of them are enabled:

```
mysql> SELECT * FROM performance_schema.setup_instruments;
+-----+-----+-----+
| NAME | ENABLED | TIMED |
+-----+-----+-----+
...
| stage/sql/end | NO | NO |
| stage/sql/executing | NO | NO |
| stage/sql/init | NO | NO |
| stage/sql/insert | NO | NO |
...
| statement/sql/load | YES | YES |
| statement/sql/grant | YES | YES |
| statement/sql/check | YES | YES |
| statement/sql/flush | YES | YES |
...
| wait/synch/mutex/sql/LOCK_global_read_lock | YES | YES |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES | YES |
| wait/synch/mutex/sql/LOCK_lock_db | YES | YES |
| wait/synch/mutex/sql/LOCK_manager | YES | YES |
...
```

|                                             |     |     |
|---------------------------------------------|-----|-----|
| wait/synch/rwlock/sql/LOCK_grant            | YES | YES |
| wait/synch/rwlock/sql/LOGGER::LOCK_logger   | YES | YES |
| wait/synch/rwlock/sql/LOCK_sys_init_connect | YES | YES |
| wait/synch/rwlock/sql/LOCK_sys_init_slave   | YES | YES |
| ...                                         |     |     |
| wait/io/file/sql/binlog                     | YES | YES |
| wait/io/file/sql/binlog_index               | YES | YES |
| wait/io/file/sql/casetest                   | YES | YES |
| wait/io/file/sql/dbopt                      | YES | YES |
| ...                                         |     |     |

To understand how to interpret instrument names, see [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

To control whether events are collected for an instrument, set its `ENABLED` value to `YES` or `NO`. For example:

```
mysql> UPDATE performance_schema.setup_instruments
 SET ENABLED = 'NO'
 WHERE NAME = 'wait/synch/mutex/sql/LOCK_mysql_create_db';
```

The Performance Schema uses collected events to update tables in the `performance_schema` database, which act as “consumers” of event information. The `setup_consumers` table lists the available consumers and which are enabled:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
| NAME | ENABLED |
+-----+-----+
| events_stages_current | NO |
| events_stages_history | NO |
| events_stages_history_long | NO |
| events_statements_current | YES |
| events_statements_history | YES |
| events_statements_history_long| NO |
| events_transactions_current | NO |
| events_transactions_history | NO |
| events_transactions_history_long| NO |
| events_waits_current | NO |
| events_waits_history | NO |
| events_waits_history_long | NO |
| global_instrumentation | YES |
| thread_instrumentation | YES |
| statements_digest | YES |
+-----+-----+
```

To control whether the Performance Schema maintains a consumer as a destination for event information, set its `ENABLED` value.

For more information about the setup tables and how to use them to control event collection, see [Section 25.4.2, “Performance Schema Event Filtering”](#).

There are some miscellaneous tables that do not fall into any of the previous groups. For example, `performance_timers` lists the available event timers and their characteristics. For information about timers, see [Section 25.4.1, “Performance Schema Event Timing”](#).

## 25.2 Performance Schema Build Configuration

The Performance Schema is mandatory and always compiled in. It is possible to exclude certain parts of the Performance Schema instrumentation. For example, to exclude stage and statement instrumentation, do this:

```
shell> cmake . \
 -DDISABLE_PSI_STAGE=1 \
 -DDISABLE_PSI_STATEMENT=1
```

For more information, see the descriptions of the `DISABLE_PSI_XXX` CMake options in [Section 2.9.7, “MySQL Source-Configuration Options”](#).

If you install MySQL over a previous installation that was configured without the Performance Schema (or with an older version of the Performance Schema that has missing or out-of-date tables). One indication of this issue is the presence of messages such as the following in the error log:

```
[ERROR] Native table 'performance_schema'. 'events_waits_history'
has the wrong structure
[ERROR] Native table 'performance_schema'. 'events_waits_history_long'
has the wrong structure
...
```

To correct that problem, perform the MySQL upgrade procedure. See [Section 2.11, “Upgrading MySQL”](#).

To verify whether a server was built with Performance Schema support, check its help output. If the Performance Schema is available, the output mentions several variables with names that begin with `performance_schema`:

```
shell> mysql --verbose --help
...
--performance_schema
 Enable the performance schema.
--performance_schema_events_waits_history_long_size=#
 Number of rows in events_waits_history_long.
...
```

You can also connect to the server and look for a line that names the `PERFORMANCE_SCHEMA` storage engine in the output from `SHOW ENGINES`:

```
mysql> SHOW ENGINES\G
...
 Engine: PERFORMANCE_SCHEMA
 Support: YES
 Comment: Performance Schema
Transactions: NO
 XA: NO
Savepoints: NO
...
```

If the Performance Schema was not configured into the server at build time, no row for `PERFORMANCE_SCHEMA` appears in the output from `SHOW ENGINES`. You might see `performance_schema` listed in the output from `SHOW DATABASES`, but it has no tables and cannot be used.

A line for `PERFORMANCE_SCHEMA` in the `SHOW ENGINES` output means that the Performance Schema is available, not that it is enabled. To enable it, you must do so at server startup, as described in the next section.

## 25.3 Performance Schema Startup Configuration

To use the MySQL Performance Schema, it must be enabled at server startup to enable event collection to occur.

Assuming that the Performance Schema is available, it is enabled by default. To enable or disable it explicitly, start the server with the `performance_schema` variable set to an appropriate value. For example, use these lines in your `my.cnf` file:

```
[mysqld]
performance_schema=ON
```

If the server is unable to allocate any internal buffer during Performance Schema initialization, the Performance Schema disables itself and sets `performance_schema` to `OFF`, and the server runs without instrumentation.

The Performance Schema also permits instrument and consumer configuration at server startup.

To control an instrument at server startup, use an option of this form:

```
--performance-schema-instrument='instrument_name=value'
```

Here, `instrument_name` is an instrument name such as `wait/synch/mutex/sql/LOCK_open`, and `value` is one of these values:

- `OFF`, `FALSE`, or `0`: Disable the instrument
- `ON`, `TRUE`, or `1`: Enable and time the instrument
- `COUNTED`: Enable and count (rather than time) the instrument

Each `--performance-schema-instrument` option can specify only one instrument name, but multiple instances of the option can be given to configure multiple instruments. In addition, patterns are permitted in instrument names to configure instruments that match the pattern. To configure all condition synchronization instruments as enabled and counted, use this option:

```
--performance-schema-instrument='wait/synch/cond/=%=COUNTED'
```

To disable all instruments, use this option:

```
--performance-schema-instrument='=%=OFF'
```

Exception: The `memory/performance_schema/%` instruments are built in and cannot be disabled at startup.

Longer instrument name strings take precedence over shorter pattern names, regardless of order. For information about specifying patterns to select instruments, see [Section 25.4.9, “Naming Instruments or Consumers for Filtering Operations”](#).

An unrecognized instrument name is ignored. It is possible that a plugin installed later may create the instrument, at which time the name is recognized and configured.

To control a consumer at server startup, use an option of this form:

```
--performance-schema-consumer=consumer_name=value
```

Here, `consumer_name` is a consumer name such as `events_waits_history`, and `value` is one of these values:

- `OFF`, `FALSE`, or `0`: Do not collect events for the consumer
- `ON`, `TRUE`, or `1`: Collect events for the consumer

For example, to enable the `events_waits_history` consumer, use this option:

```
--performance-schema-consumer-events-waits-history=ON
```

The permitted consumer names can be found by examining the `setup_consumers` table. Patterns are not permitted. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent.

The Performance Schema includes several system variables that provide configuration information:

```
mysql> SHOW VARIABLES LIKE 'perf%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| performance_schema | ON |
| performance_schema_accounts_size | 100 |
| performance_schema_digests_size | 200 |
| performance_schema_events_stages_history_long_size | 10000 |
| performance_schema_events_stages_history_size | 10 |
| performance_schema_events_statements_history_long_size | 10000 |
| performance_schema_events_statements_history_size | 10 |
| performance_schema_events_waits_history_long_size | 10000 |
| performance_schema_events_waits_history_size | 10 |
| performance_schema_hosts_size | 100 |
| performance_schema_max_cond_classes | 80 |
+-----+-----+
```

|                                       |      |
|---------------------------------------|------|
| performance_schema_max_cond_instances | 1000 |
| ...                                   |      |

The `performance_schema` variable is `ON` or `OFF` to indicate whether the Performance Schema is enabled or disabled. The other variables indicate table sizes (number of rows) or memory allocation values.

#### Note

With the Performance Schema enabled, the number of Performance Schema instances affects the server memory footprint, perhaps to a large extent. The Performance Schema autoscales many parameters to use memory only as required; see [Section 25.17, “The Performance Schema Memory-Allocation Model”](#).

To change the value of Performance Schema system variables, set them at server startup. For example, put the following lines in a `my.cnf` file to change the sizes of the history tables for wait events:

```
[mysqld]
performance_schema
performance_schema_events_waits_history_size=20
performance_schema_events_waits_history_long_size=15000
```

The Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For example, it sizes the parameters that control the sizes of the events waits tables this way. The Performance Schema allocates memory incrementally, scaling its memory use to actual server load, instead of allocating all the memory it needs during server startup. Consequently, many sizing parameters need not be set at all. To see which parameters are autosized or autoscaled, use `mysqld --verbose --help` and examine the option descriptions, or see [Section 25.15, “Performance Schema System Variables”](#).

For each autosized parameter that is not set at server startup, the Performance Schema determines how to set its value based on the value of the following system values, which are considered as “hints” about how you have configured your MySQL server:

```
max_connections
open_files_limit
table_definition_cache
table_open_cache
```

To override autosizing or autoscaling for a given parameter, set it to a value other than `-1` at startup. In this case, the Performance Schema assigns it the specified value.

At runtime, `SHOW VARIABLES` displays the actual values that autosized parameters were set to. Autoscaled parameters display with a value of `-1`.

If the Performance Schema is disabled, its autosized and autoscaled parameters remain set to `-1` and `SHOW VARIABLES` displays `-1`.

## 25.4 Performance Schema Runtime Configuration

Specific Performance Schema features can be enabled at runtime to control which types of event collection occur.

Performance Schema setup tables contain information about monitoring configuration:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
 WHERE TABLE_SCHEMA = 'performance_schema'
 AND TABLE_NAME LIKE 'setup%';
+-----+
| TABLE_NAME |
+-----+
| setup_actors |
| setup_consumers |
+-----+
```

```
| setup_instruments |
| setup_objects |
| setup_timers |
+-----+
```

You can examine the contents of these tables to obtain information about Performance Schema monitoring characteristics. If you have the `UPDATE` privilege, you can change Performance Schema operation by modifying setup tables to affect how monitoring occurs. For additional details about these tables, see [Section 25.12.2, “Performance Schema Setup Tables”](#).

To see which event timers are selected, query the `setup_timers` tables:

```
mysql> SELECT * FROM performance_schema.setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| idle | MICROSECOND |
| wait | CYCLE |
| stage | NANOSECOND |
| statement | NANOSECOND |
| transaction | NANOSECOND |
+-----+-----+
```

The `NAME` value indicates the type of instrument to which the timer applies, and `TIMER_NAME` indicates which timer applies to those instruments. The timer applies to instruments where their name begins with an element matching the `NAME` value.

To change the timer, update the `NAME` value. For example, to use the `NANOSECOND` timer for the `wait` timer:

```
mysql> UPDATE performance_schema.setup_timers
 SET TIMER_NAME = 'NANOSECOND'
 WHERE NAME = 'wait';
mysql> SELECT * FROM performance_schema.setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| idle | MICROSECOND |
| wait | NANOSECOND |
| stage | NANOSECOND |
| statement | NANOSECOND |
| transaction | NANOSECOND |
+-----+-----+
```

For discussion of timers, see [Section 25.4.1, “Performance Schema Event Timing”](#).

The `setup_instruments` and `setup_consumers` tables list the instruments for which events can be collected and the types of consumers for which event information actually is collected, respectively. Other setup tables enable further modification of the monitoring configuration. [Section 25.4.2, “Performance Schema Event Filtering”](#), discusses how you can modify these tables to affect event collection.

If there are Performance Schema configuration changes that must be made at runtime using SQL statements and you would like these changes to take effect each time the server starts, put the statements in a file and start the server with the `init_file` system variable set to name the file. This strategy can also be useful if you have multiple monitoring configurations, each tailored to produce a different kind of monitoring, such as casual server health monitoring, incident investigation, application behavior troubleshooting, and so forth. Put the statements for each monitoring configuration into their own file and specify the appropriate file as the `init_file` value when you start the server.

## 25.4.1 Performance Schema Event Timing

Events are collected by means of instrumentation added to the server source code. Instruments time events, which is how the Performance Schema provides an idea of how long events take. It is also possible to configure instruments not to collect timing information. This section discusses the available timers and their characteristics, and how timing values are represented in events.

## Performance Schema Timers

Two Performance Schema tables provide timer information:

- `performance_timers` lists the available timers and their characteristics.
- `setup_timers` indicates which timers are used for which instruments.

Each timer row in `setup_timers` must refer to one of the timers listed in `performance_timers`.

Timers vary in precision and amount of overhead. To see what timers are available and their characteristics, check the `performance_timers` table:

```
mysql> SELECT * FROM performance_schema.performance_timers;
+-----+-----+-----+-----+
| TIMER_NAME | TIMER_FREQUENCY | TIMER_RESOLUTION | TIMER_OVERHEAD |
+-----+-----+-----+-----+
| CYCLE | 2389029850 | 1 | 72 |
| NANOSECOND | 1000000000 | 1 | 112 |
| MICROSECOND | 1000000 | 1 | 136 |
| MILLISECOND | 1036 | 1 | 168 |
| TICK | 105 | 1 | 2416 |
+-----+-----+-----+-----+
```

If the values associated with a given timer name are `NULL`, that timer is not supported on your platform. The rows that do not contain `NULL` indicate which timers you can use in `setup_timers`.

The columns have these meanings:

- The `TIMER_NAME` column shows the names of the available timers. `CYCLE` refers to the timer that is based on the CPU (processor) cycle counter. The timers in `setup_timers` that you can use are those that do not have `NULL` in the other columns. If the values associated with a given timer name are `NULL`, that timer is not supported on your platform.
- `TIMER_FREQUENCY` indicates the number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. The value shown was obtained on a system with a 2.4GHz processor. The other timers are based on fixed fractions of seconds. For `TICK`, the frequency may vary by platform (for example, some use 100 ticks/second, others 1000 ticks/second).
- `TIMER_RESOLUTION` indicates the number of timer units by which timer values increase at a time. If a timer has a resolution of 10, its value increases by 10 each time.
- `TIMER_OVERHEAD` is the minimal number of cycles of overhead to obtain one timing with the given timer. The overhead per event is twice the value displayed because the timer is invoked at the beginning and end of the event.

To see which timers are in effect or to change timers, access the `setup_timers` table:

```
mysql> SELECT * FROM performance_schema.setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| idle | MICROSECOND |
| wait | CYCLE |
| stage | NANOSECOND |
| statement | NANOSECOND |
| transaction | NANOSECOND |
+-----+-----+

mysql> UPDATE performance_schema.setup_timers
 SET TIMER_NAME = 'MICROSECOND'
 WHERE NAME = 'idle';
mysql> SELECT * FROM performance_schema.setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| idle | MICROSECOND |
| wait | CYCLE |
```

|             |            |
|-------------|------------|
| stage       | NANOSECOND |
| statement   | NANOSECOND |
| transaction | NANOSECOND |

By default, the Performance Schema uses the best timer available for each instrument type, but you can select a different one.

To time wait events, the most important criterion is to reduce overhead, at the possible expense of the timer accuracy, so using the `CYCLE` timer is the best.

The time a statement (or stage) takes to execute is in general orders of magnitude larger than the time it takes to execute a single wait. To time statements, the most important criterion is to have an accurate measure, which is not affected by changes in processor frequency, so using a timer which is not based on cycles is the best. The default timer for statements is `NANOSECOND`. The extra “overhead” compared to the `CYCLE` timer is not significant, because the overhead caused by calling a timer twice (once when the statement starts, once when it ends) is orders of magnitude less compared to the CPU time used to execute the statement itself. Using the `CYCLE` timer has no benefit here, only drawbacks.

The precision offered by the cycle counter depends on processor speed. If the processor runs at 1 GHz (one billion cycles/second) or higher, the cycle counter delivers sub-nanosecond precision. Using the cycle counter is much cheaper than getting the actual time of day. For example, the standard `gettimeofday()` function can take hundreds of cycles, which is an unacceptable overhead for data gathering that may occur thousands or millions of times per second.

Cycle counters also have disadvantages:

- End users expect to see timings in wall-clock units, such as fractions of a second. Converting from cycles to fractions of seconds can be expensive. For this reason, the conversion is a quick and fairly rough multiplication operation.
- Processor cycle rate might change, such as when a laptop goes into power-saving mode or when a CPU slows down to reduce heat generation. If a processor's cycle rate fluctuates, conversion from cycles to real-time units is subject to error.
- Cycle counters might be unreliable or unavailable depending on the processor or the operating system. For example, on Pentiums, the instruction is `RDTSC` (an assembly-language rather than a C instruction) and it is theoretically possible for the operating system to prevent user-mode programs from using it.
- Some processor details related to out-of-order execution or multiprocessor synchronization might cause the counter to seem fast or slow by up to 1000 cycles.

MySQL works with cycle counters on x386 (Windows, macOS, Linux, Solaris, and other Unix flavors), PowerPC, and IA-64.

## Performance Schema Timer Representation in Events

Rows in Performance Schema tables that store current events and historical events have three columns to represent timing information: `TIMER_START` and `TIMER_END` indicate when an event started and finished, and `TIMER_WAIT` indicates event duration.

The `setup_instruments` table has an `ENABLED` column to indicate the instruments for which to collect events. The table also has a `TIMED` column to indicate which instruments are timed. If an instrument is not enabled, it produces no events. If an enabled instrument is not timed, events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating aggregate time values in summary tables (sum, minimum, maximum, and average).

Internally, times within events are stored in units given by the timer in effect when event timing begins. For display when events are retrieved from Performance Schema tables, times are shown in picoseconds (trillions of a second) to normalize them to a standard unit, regardless of which timer is selected.

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time. To avoid unpredictable results after you make timer changes, use `TRUNCATE TABLE` to reset Performance Schema statistics.

The timer baseline (“time zero”) occurs at Performance Schema initialization during server startup. `TIMER_START` and `TIMER_END` values in events represent picoseconds since the baseline. `TIMER_WAIT` values are durations in picoseconds.

Picosecond values in events are approximate. Their accuracy is subject to the usual forms of error associated with conversion from one unit to another. If the `CYCLE` timer is used and the processor rate varies, there might be drift. For these reasons, it is not reasonable to look at the `TIMER_START` value for an event as an accurate measure of time elapsed since server startup. On the other hand, it is reasonable to use `TIMER_START` or `TIMER_WAIT` values in `ORDER BY` clauses to order events by start time or duration.

The choice of picoseconds in events rather than a value such as microseconds has a performance basis. One implementation goal was to show results in a uniform time unit, regardless of the timer. In an ideal world this time unit would look like a wall-clock unit and be reasonably precise; in other words, microseconds. But to convert cycles or nanoseconds to microseconds, it would be necessary to perform a division for every instrumentation. Division is expensive on many platforms. Multiplication is not expensive, so that is what is used. Therefore, the time unit is an integer multiple of the highest possible `TIMER_FREQUENCY` value, using a multiplier large enough to ensure that there is no major precision loss. The result is that the time unit is “picoseconds.” This precision is spurious, but the decision enables overhead to be minimized.

While a wait, stage, statement, or transaction event is executing, the respective current-event tables display current-event timing information:

```
events_waits_current
events_stages_current
events_statements_current
events_transactions_current
```

To make it possible to determine how long a not-yet-completed event has been running, the timer columns are set as follows:

- `TIMER_START` is populated.
- `TIMER_END` is populated with the current timer value.
- `TIMER_WAIT` is populated with the time elapsed so far (`TIMER_END - TIMER_START`).

Events that have not yet completed have an `END_EVENT_ID` value of `NULL`. To assess time elapsed so far for an event, use the `TIMER_WAIT` column. Therefore, to identify events that have not yet completed and have taken longer than `N` picoseconds thus far, monitoring applications can use this expression in queries:

```
WHERE END_EVENT_ID IS NULL AND TIMER_WAIT > N
```

Event identification as just described assumes that the corresponding instruments have `ENABLED` and `TIMED` set to `YES` and that the relevant consumers are enabled.

## 25.4.2 Performance Schema Event Filtering

Events are processed in a producer/consumer fashion:

- Instrumented code is the source for events and produces events to be collected. The `setup_instruments` table lists the instruments for which events can be collected, whether they are enabled, and (for enabled instruments) whether to collect timing information:

```
mysql> SELECT * FROM performance_schema.setup_instruments;
+-----+-----+-----+
```

| NAME                                              | ENABLED | TIMED |
|---------------------------------------------------|---------|-------|
| ...                                               |         |       |
| wait/synch/mutex/sql/LOCK_global_read_lock        | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db                 | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager                 | YES     | YES   |
| ...                                               |         |       |

The `setup_instruments` table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in [Section 25.4.3, “Event Pre-Filtering”](#).

- Performance Schema tables are the destinations for events and consume events. The `setup_consumers` table lists the types of consumers to which event information can be sent and whether they are enabled:

| mysql> SELECT * FROM performance_schema.setup_consumers; |         |
|----------------------------------------------------------|---------|
| NAME                                                     | ENABLED |
| events_stages_current                                    | NO      |
| events_stages_history                                    | NO      |
| events_stages_history_long                               | NO      |
| events_statements_current                                | YES     |
| events_statements_history                                | YES     |
| events_statements_history_long                           | NO      |
| events_transactions_current                              | NO      |
| events_transactions_history                              | NO      |
| events_transactions_history_long                         | NO      |
| events_waits_current                                     | NO      |
| events_waits_history                                     | NO      |
| events_waits_history_long                                | NO      |
| global_instrumentation                                   | YES     |
| thread_instrumentation                                   | YES     |
| statements_digest                                        | YES     |

Filtering can be done at different stages of performance monitoring:

- **Pre-filtering.** This is done by modifying Performance Schema configuration so that only certain types of events are collected from producers, and collected events update only certain consumers. To do this, enable or disable instruments or consumers. Pre-filtering is done by the Performance Schema and has a global effect that applies to all users.

Reasons to use pre-filtering:

- To reduce overhead. Performance Schema overhead should be minimal even with all instruments enabled, but perhaps you want to reduce it further. Or you do not care about timing events and want to disable the timing code to eliminate timing overhead.
- To avoid filling the current-events or history tables with events in which you have no interest. Pre-filtering leaves more “room” in these tables for instances of rows for enabled instrument types. If you enable only file instruments with pre-filtering, no rows are collected for nonfile instruments. With post-filtering, nonfile events are collected, leaving fewer rows for file events.
- To avoid maintaining some kinds of event tables. If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about event histories, you can disable the history table consumers to improve performance.

- **Post-filtering.** This involves the use of `WHERE` clauses in queries that select information from Performance Schema tables, to specify which of the available events you want to see. Post-filtering is performed on a per-user basis because individual users select which of the available events are of interest.

Reasons to use post-filtering:

- To avoid making decisions for individual users about which event information is of interest.
- To use the Performance Schema to investigate a performance issue when the restrictions to impose using pre-filtering are not known in advance.

The following sections provide more detail about pre-filtering and provide guidelines for naming instruments or consumers in filtering operations. For information about writing queries to retrieve information (post-filtering), see [Section 25.5, “Performance Schema Queries”](#).

### 25.4.3 Event Pre-Filtering

Pre-filtering is done by the Performance Schema and has a global effect that applies to all users. Pre-filtering can be applied to either the producer or consumer stage of event processing:

- To configure pre-filtering at the producer stage, several tables can be used:
  - `setup_instruments` indicates which instruments are available. An instrument disabled in this table produces no events regardless of the contents of the other production-related setup tables. An instrument enabled in this table is permitted to produce events, subject to the contents of the other tables.
  - `setup_objects` controls whether the Performance Schema monitors particular table and stored program objects.
  - `threads` indicates whether monitoring is enabled for each server thread.
  - `setup_actors` determines the initial monitoring state for new foreground threads.
- To configure pre-filtering at the consumer stage, modify the `setup_consumers` table. This determines the destinations to which events are sent. `setup_consumers` also implicitly affects event production. If a given event is not sent to any destination (is not consumed), the Performance Schema does not produce it.

Modifications to any of these tables affect monitoring immediately, with some exceptions:

- Modifications to some instruments in the `setup_instruments` table are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true. This restriction is lifted as of MySQL 5.7.12.
- Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads.

When you change the monitoring configuration, the Performance Schema does not flush the history tables. Events already collected remain in the current-events and history tables until displaced by newer events. If you disable instruments, you might need to wait a while before events for them are displaced by newer events of interest. Alternatively, use `TRUNCATE TABLE` to empty the history tables.

After making instrumentation changes, you might want to truncate the summary tables. Generally, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

The following sections describe how to use specific tables to control Performance Schema pre-filtering.

### 25.4.4 Pre-Filtering by Instrument

The `setup_instruments` table lists the available instruments:

```
mysql> SELECT * FROM performance_schema.setup_instruments;
+-----+-----+-----+
| NAME | ENABLED | TIMED |
+-----+-----+-----+
...
| stage/sql/end | NO | NO |
| stage/sql/executing | NO | NO |
| stage/sql/init | NO | NO |
| stage/sql/insert | NO | NO |
...
| statement/sql/load | YES | YES |
| statement/sql/grant | YES | YES |
| statement/sql/check | YES | YES |
| statement/sql/flush | YES | YES |
...
| wait/synch/mutex/sql/LOCK_global_read_lock | YES | YES |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES | YES |
| wait/synch/mutex/sql/LOCK_lock_db | YES | YES |
| wait/synch/mutex/sql/LOCK_manager | YES | YES |
...
| wait/synch/rwlock/sql/LOCK_grant | YES | YES |
| wait/synch/rwlock/sql/LOGGER::LOCK_logger | YES | YES |
| wait/synch/rwlock/sql/LOCK_sys_init_connect | YES | YES |
| wait/synch/rwlock/sql/LOCK_sys_init_slave | YES | YES |
...
| wait/io/file/sql/binlog | YES | YES |
| wait/io/file/sql/binlog_index | YES | YES |
| wait/io/file/sql/casetest | YES | YES |
| wait/io/file/sql/dbopt | YES | YES |
...

```

To control whether an instrument is enabled, set its `ENABLED` column to `YES` or `NO`. To configure whether to collect timing information for an enabled instrument, set its `TIMED` value to `YES` or `NO`. Setting the `TIMED` column affects Performance Schema table contents as described in [Section 25.4.1, “Performance Schema Event Timing”](#).

Modifications to most `setup_instruments` rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

The `setup_instruments` table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in [Section 25.4.3, “Event Pre-Filtering”](#).

The following examples demonstrate possible operations on the `setup_instruments` table. These changes, like other pre-filtering operations, affect all users. Some of these queries use the `LIKE` operator and a pattern match instrument names. For additional information about specifying patterns to select instruments, see [Section 25.4.9, “Naming Instruments or Consumers for Filtering Operations”](#).

- Disable all instruments:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO';
```

Now no events are collected.

- Disable all file instruments, adding them to the current set of disabled instruments:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME LIKE 'wait/io/file/%';
```

- Disable only file instruments, enable all other instruments:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = IF(NAME LIKE 'wait/io/file/%', 'NO', 'YES');
```

- Enable all but those instruments in the `mysys` library:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = CASE WHEN NAME LIKE '%/mysys/%' THEN 'YES' ELSE 'NO' END;
```

- Disable a specific instrument:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

- To toggle the state of an instrument, “flip” its `ENABLED` value:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = IF(ENABLED = 'YES', 'NO', 'YES')
WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

- Disable timing for all events:

```
UPDATE performance_schema.setup_instruments
SET TIMED = 'NO';
```

## 25.4.5 Pre-Filtering by Object

The `setup_objects` table controls whether the Performance Schema monitors particular table and stored program objects. The initial `setup_objects` contents look like this:

```
mysql> SELECT * FROM performance_schema.setup_objects;
+-----+-----+-----+-----+-----+
| OBJECT_TYPE | OBJECT_SCHEMA | OBJECT_NAME | ENABLED | TIMED |
+-----+-----+-----+-----+-----+
| EVENT | mysql | % | NO | NO |
| EVENT | performance_schema | % | NO | NO |
| EVENT | information_schema | % | NO | NO |
| EVENT | % | % | YES | YES |
| FUNCTION | mysql | % | NO | NO |
| FUNCTION | performance_schema | % | NO | NO |
| FUNCTION | information_schema | % | NO | NO |
| FUNCTION | % | % | YES | YES |
| PROCEDURE | mysql | % | NO | NO |
| PROCEDURE | performance_schema | % | NO | NO |
| PROCEDURE | information_schema | % | NO | NO |
| PROCEDURE | % | % | YES | YES |
| TABLE | mysql | % | NO | NO |
| TABLE | performance_schema | % | NO | NO |
| TABLE | information_schema | % | NO | NO |
| TABLE | % | % | YES | YES |
| TRIGGER | mysql | % | NO | NO |
| TRIGGER | performance_schema | % | NO | NO |
| TRIGGER | information_schema | % | NO | NO |
| TRIGGER | % | % | YES | YES |
+-----+-----+-----+-----+-----+
```

Modifications to the `setup_objects` table affect object monitoring immediately.

The `OBJECT_TYPE` column indicates the type of object to which a row applies. `TABLE` filtering affects table I/O events (`wait/io/table/sql/handler` instrument) and table lock events (`wait/lock/table/sql/handler` instrument).

The `OBJECT_SCHEMA` and `OBJECT_NAME` columns should contain a literal schema or object name, or '`%`' to match any name.

The `ENABLED` column indicates whether matching objects are monitored, and `TIMED` indicates whether to collect timing information. Setting the `TIMED` column affects Performance Schema table contents as described in [Section 25.4.1, “Performance Schema Event Timing”](#).

The effect of the default object configuration is to instrument all objects except those in the `mysql`, `INFORMATION_SCHEMA`, and `performance_schema` databases. (Tables in

the `INFORMATION_SCHEMA` database are not instrumented regardless of the contents of `setup_objects`; the row for `information_schema.%` simply makes this default explicit.)

When the Performance Schema checks for a match in `setup_objects`, it tries to find more specific matches first. For rows that match a given `OBJECT_TYPE`, the Performance Schema checks rows in this order:

- Rows with `OBJECT_SCHEMA='literal'` and `OBJECT_NAME='literal'`.
- Rows with `OBJECT_SCHEMA='literal'` and `OBJECT_NAME='%'`.
- Rows with `OBJECT_SCHEMA='%'` and `OBJECT_NAME='%'`.

For example, with a table `db1.t1`, the Performance Schema looks in `TABLE` rows for a match for '`db1`' and '`t1`', then for '`db1`' and '`%`', then for '`%`' and '`%`'. The order in which matching occurs matters because different matching `setup_objects` rows can have different `ENABLED` and `TIMED` values.

For table-related events, the Performance Schema combines the contents of `setup_objects` with `setup_instruments` to determine whether to enable instruments and whether to time enabled instruments:

- For tables that match a row in `setup_objects`, table instruments produce events only if `ENABLED` is `YES` in both `setup_instruments` and `setup_objects`.
- The `TIMED` values in the two tables are combined, so that timing information is collected only when both values are `YES`.

For stored program objects, the Performance Schema takes the `ENABLED` and `TIMED` columns directly from the `setup_objects` row. There is no combining of values with `setup_instruments`.

Suppose that `setup_objects` contains the following `TABLE` rows that apply to `db1`, `db2`, and `db3`:

| OBJECT_TYPE | OBJECT_SCHEMA | OBJECT_NAME | ENABLED | TIMED |
|-------------|---------------|-------------|---------|-------|
| TABLE       | db1           | t1          | YES     | YES   |
| TABLE       | db1           | t2          | NO      | NO    |
| TABLE       | db2           | %           | YES     | YES   |
| TABLE       | db3           | %           | NO      | NO    |
| TABLE       | %             | %           | YES     | YES   |

If an object-related instrument in `setup_instruments` has an `ENABLED` value of `NO`, events for the object are not monitored. If the `ENABLED` value is `YES`, event monitoring occurs according to the `ENABLED` value in the relevant `setup_objects` row:

- `db1.t1` events are monitored
- `db1.t2` events are not monitored
- `db2.t3` events are monitored
- `db3.t4` events are not monitored
- `db4.t5` events are monitored

Similar logic applies for combining the `TIMED` columns from the `setup_instruments` and `setup_objects` tables to determine whether to collect event timing information.

If a persistent table and a temporary table have the same name, matching against `setup_objects` rows occurs the same way for both. It is not possible to enable monitoring for one table but not the other. However, each table is instrumented separately.

## 25.4.6 Pre-Filtering by Thread

The `threads` table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring is enabled for it. For the Performance Schema to monitor a thread, these things must be true:

- The `thread_instrumentation` consumer in the `setup_consumers` table must be `YES`.
- The `threads.INSTRUMENTED` column must be `YES`.
- Monitoring occurs only for those thread events produced from instruments that are enabled in the `setup_instruments` table.

The `threads` table also indicates for each server thread whether to perform historical event logging. This includes wait, stage, statement, and transaction events and affects logging to these tables:

```
events_waits_history
events_waits_history_long
events_stages_history
events_stages_history_long
events_statements_history
events_statements_history_long
events_transactions_history
events_transactions_history_long
```

For historical event logging to occur, these things must be true:

- The appropriate history-related consumers in the `setup_consumers` table must be enabled. For example, wait event logging in the `events_waits_history` and `events_waits_history_long` tables requires the corresponding `events_waits_history` and `events_waits_history_long` consumers to be `YES`.
- The `threads.HISTORY` column must be `YES`.
- Logging occurs only for those thread events produced from instruments that are enabled in the `setup_instruments` table.

For foreground threads (resulting from client connections), the initial values of the `INSTRUMENTED` and `HISTORY` columns in `threads` table rows are determined by whether the user account associated with a thread matches any row in the `setup_actors` table. The values come from the `ENABLED` and `HISTORY` columns of the matching `setup_actors` table row.

For background threads, there is no associated user. `INSTRUMENTED` and `HISTORY` are `YES` by default and `setup_actors` is not consulted.

The initial `setup_actors` contents look like this:

```
mysql> SELECT * FROM performance_schema.setup_actors;
+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+
| % | % | % | YES | YES |
+-----+-----+-----+-----+
```

The `HOST` and `USER` columns should contain a literal host or user name, or `'%'` to match any name.

The `ENABLED` and `HISTORY` columns indicate whether to enable instrumentation and historical event logging for matching threads, subject to the other conditions described previously.

When the Performance Schema checks for a match for each new foreground thread in `setup_actors`, it tries to find more specific matches first, using the `USER` and `HOST` columns (`ROLE` is unused):

- Rows with `USER='literal'` and `HOST='literal'`.
- Rows with `USER='literal'` and `HOST='%'`.

- Rows with `USER='%'` and `HOST=literal`.
- Rows with `USER='%'` and `HOST='%'`.

The order in which matching occurs matters because different matching `setup_actors` rows can have different `USER` and `HOST` values. This enables instrumenting and historical event logging to be applied selectively per host, user, or account (user and host combination), based on the `ENABLED` and `HISTORY` column values:

- When the best match is a row with `ENABLED=YES`, the `INSTRUMENTED` value for the thread becomes `YES`. When the best match is a row with `HISTORY=YES`, the `HISTORY` value for the thread becomes `YES`.
- When the best match is a row with `ENABLED=NO`, the `INSTRUMENTED` value for the thread becomes `NO`. When the best match is a row with `HISTORY=NO`, the `HISTORY` value for the thread becomes `NO`.
- When no match is found, the `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.

The `ENABLED` and `HISTORY` columns in `setup_actors` rows can be set to `YES` or `NO` independent of one another. This means you can enable instrumentation separately from whether you collect historical events.

By default, monitoring and historical event collection are enabled for all new foreground threads because the `setup_actors` table initially contains a row with `'%'` for both `HOST` and `USER`. To perform more limited matching such as to enable monitoring only for some foreground threads, you must change this row because it matches any connection, and add rows for more specific `HOST/USER` combinations.

Suppose that you modify `setup_actors` as follows:

```
UPDATE performance_schema.setup_actors
SET ENABLED = 'NO', HISTORY = 'NO'
WHERE HOST = '%' AND USER = '%';
INSERT INTO performance_schema.setup_actors
(HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('localhost','joe','%','YES','YES');
INSERT INTO performance_schema.setup_actors
(HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('hosta.example.com','joe','%','YES','NO');
INSERT INTO performance_schema.setup_actors
(HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('%','sam','%','NO','YES');
```

The `UPDATE` statement changes the default match to disable instrumentation and historical event collection. The `INSERT` statements add rows for more specific matches.

Now the Performance Schema determines how to set the `INSTRUMENTED` and `HISTORY` values for new connection threads as follows:

- If `joe` connects from the local host, the connection matches the first inserted row. The `INSTRUMENTED` and `HISTORY` values for the thread become `YES`.
- If `joe` connects from `hosta.example.com`, the connection matches the second inserted row. The `INSTRUMENTED` value for the thread becomes `YES` and the `HISTORY` value becomes `NO`.
- If `joe` connects from any other host, there is no match. The `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.
- If `sam` connects from any host, the connection matches the third inserted row. The `INSTRUMENTED` value for the thread becomes `NO` and the `HISTORY` value becomes `YES`.
- For any other connection, the row with `HOST` and `USER` set to `'%'` matches. This row now has `ENABLED` and `HISTORY` set to `NO`, so the `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.

Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the `INSTRUMENTED` and `HISTORY` columns of `threads` table rows.

## 25.4.7 Pre-Filtering by Consumer

The `setup_consumers` table lists the available consumer types and which are enabled:

| NAME                             | ENABLED |
|----------------------------------|---------|
| events_stages_current            | NO      |
| events_stages_history            | NO      |
| events_stages_history_long       | NO      |
| events_statements_current        | YES     |
| events_statements_history        | YES     |
| events_statements_history_long   | NO      |
| events_transactions_current      | NO      |
| events_transactions_history      | NO      |
| events_transactions_history_long | NO      |
| events_waits_current             | NO      |
| events_waits_history             | NO      |
| events_waits_history_long        | NO      |
| global_instrumentation           | YES     |
| thread_instrumentation           | YES     |
| statements_digest                | YES     |

Modify the `setup_consumers` table to affect pre-filtering at the consumer stage and determine the destinations to which events are sent. To enable or disable a consumer, set its `ENABLED` value to `YES` or `NO`.

Modifications to the `setup_consumers` table affect monitoring immediately.

If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about historical event information, disable the history consumers:

```
UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE '%history%';
```

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following principles apply:

- Destinations associated with a consumer receive no events unless the Performance Schema checks the consumer and the consumer is enabled.
- A consumer is checked only if all consumers it depends on (if any) are enabled.
- If a consumer is not checked, or is checked but is disabled, other consumers that depend on it are not checked.
- Dependent consumers may have their own dependent consumers.
- If an event would not be sent to any destination, the Performance Schema does not produce it.

The following lists describe the available consumer values. For discussion of several representative consumer configurations and their effect on instrumentation, see [Section 25.4.8, “Example Consumer Configurations”](#).

- [Global and Thread Consumers](#)
- [Wait Event Consumers](#)
- [Stage Event Consumers](#)

- Statement Event Consumers
- Transaction Event Consumers
- Statement Digest Consumer

## Global and Thread Consumers

- `global_instrumentation` is the highest level consumer. If `global_instrumentation` is `NO`, it disables global instrumentation. All other settings are lower level and are not checked; it does not matter what they are set to. No global or per thread information is maintained and no individual events are collected in the current-events or event-history tables. If `global_instrumentation` is `YES`, the Performance Schema maintains information for global states and also checks the `thread_instrumentation` consumer.
- `thread_instrumentation` is checked only if `global_instrumentation` is `YES`. Otherwise, if `thread_instrumentation` is `NO`, it disables thread-specific instrumentation and all lower-level settings are ignored. No information is maintained per thread and no individual events are collected in the current-events or event-history tables. If `thread_instrumentation` is `YES`, the Performance Schema maintains thread-specific information and also checks `events_xxx_current` consumers.

## Wait Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_waits_current`, if `NO`, disables collection of individual wait events in the `events_waits_current` table. If `YES`, it enables wait event collection and the Performance Schema checks the `events_waits_history` and `events_waits_history_long` consumers.
- `events_waits_history` is not checked if `event_waits_current` is `NO`. Otherwise, an `events_waits_history` value of `NO` or `YES` disables or enables collection of wait events in the `events_waits_history` table.
- `events_waits_history_long` is not checked if `event_waits_current` is `NO`. Otherwise, an `events_waits_history_long` value of `NO` or `YES` disables or enables collection of wait events in the `events_waits_history_long` table.

## Stage Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_stages_current`, if `NO`, disables collection of individual stage events in the `events_stages_current` table. If `YES`, it enables stage event collection and the Performance Schema checks the `events_stages_history` and `events_stages_history_long` consumers.
- `events_stages_history` is not checked if `event_stages_current` is `NO`. Otherwise, an `events_stages_history` value of `NO` or `YES` disables or enables collection of stage events in the `events_stages_history` table.
- `events_stages_history_long` is not checked if `event_stages_current` is `NO`. Otherwise, an `events_stages_history_long` value of `NO` or `YES` disables or enables collection of stage events in the `events_stages_history_long` table.

## Statement Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_statements_current`, if `NO`, disables collection of individual statement events in the `events_statements_current` table. If `YES`, it enables statement event collection and the Performance Schema checks the `events_statements_history` and `events_statements_history_long` consumers.
- `events_statements_history` is not checked if `events_statements_current` is `NO`. Otherwise, an `events_statements_history` value of `NO` or `YES` disables or enables collection of statement events in the `events_statements_history` table.
- `events_statements_history_long` is not checked if `events_statements_current` is `NO`. Otherwise, an `events_statements_history_long` value of `NO` or `YES` disables or enables collection of statement events in the `events_statements_history_long` table.

## Transaction Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_transactions_current`, if `NO`, disables collection of individual transaction events in the `events_transactions_current` table. If `YES`, it enables transaction event collection and the Performance Schema checks the `events_transactions_history` and `events_transactions_history_long` consumers.
- `events_transactions_history` is not checked if `events_transactions_current` is `NO`. Otherwise, an `events_transactions_history` value of `NO` or `YES` disables or enables collection of transaction events in the `events_transactions_history` table.
- `events_transactions_history_long` is not checked if `events_transactions_current` is `NO`. Otherwise, an `events_transactions_history_long` value of `NO` or `YES` disables or enables collection of transaction events in the `events_transactions_history_long` table.

## Statement Digest Consumer

The `statements_digest` consumer requires `global_instrumentation` to be `YES` or it is not checked. There is no dependency on the statement event consumers, so you can obtain statistics per digest without having to collect statistics in `events_statements_current`, which is advantageous in terms of overhead. Conversely, you can get detailed statements in `events_statements_current` without digests (the `DIGEST` and `DIGEST_TEXT` columns are `NULL`).

For more information about statement digesting, see [Section 25.10, “Performance Schema Statement Digests”](#).

### 25.4.8 Example Consumer Configurations

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following discussion describes how consumers work, showing specific configurations and their effects as consumer settings are enabled progressively from high to low. The consumer values shown are representative. The general principles described here apply to other consumer values that may be available.

The configuration descriptions occur in order of increasing functionality and overhead. If you do not need the information provided by enabling lower-level settings, disable them and the Performance Schema executes less code on your behalf and you have less information to sift through.

The `setup_consumers` table contains the following hierarchy of values:

```
global_instrumentation
 thread_instrumentation
 events_waits_current
 events_waits_history
 events_waits_history_long
 events_stages_current
 events_stages_history
```

```

events_stages_history_long
events_statements_current
events_statements_history
events_statements_history_long
events_transactions_current
events_transactions_history
events_transactions_history_long
statements_digest

```

**Note**

In the consumer hierarchy, the consumers for waits, stages, statements, and transactions are all at the same level. This differs from the event nesting hierarchy, for which wait events nest within stage events, which nest within statement events, which nest within transaction events.

If a given consumer setting is `NO`, the Performance Schema disables the instrumentation associated with the consumer and ignores all lower-level settings. If a given setting is `YES`, the Performance Schema enables the instrumentation associated with it and checks the settings at the next lowest level. For a description of the rules for each consumer, see [Section 25.4.7, “Pre-Filtering by Consumer”](#).

For example, if `global_instrumentation` is enabled, `thread_instrumentation` is checked. If `thread_instrumentation` is enabled, the `events_xxx_current` consumers are checked. If of these `events_waits_current` is enabled, `events_waits_history` and `events_waits_history_long` are checked.

Each of the following configuration descriptions indicates which setup elements the Performance Schema checks and which output tables it maintains (that is, for which tables it collects information).

- No Instrumentation
- Global Instrumentation Only
- Global and Thread Instrumentation Only
- Global, Thread, and Current-Event Instrumentation
- Global, Thread, Current-Event, and Event-History instrumentation

## No Instrumentation

Server configuration state:

```

mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
| NAME | ENABLED |
+-----+-----+
| global_instrumentation | NO |
...
+-----+-----+

```

In this configuration, nothing is instrumented.

Setup elements checked:

- Table `setup_consumers`, consumer `global_instrumentation`

Output tables maintained:

- None

## Global Instrumentation Only

Server configuration state:

```

mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+

```

| NAME                   | ENABLED |
|------------------------|---------|
| global_instrumentation | YES     |
| thread_instrumentation | NO      |
| ...                    |         |

In this configuration, instrumentation is maintained only for global states. Per-thread instrumentation is disabled.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumer `thread_instrumentation`
- Table `setup_instruments`
- Table `setup_objects`
- Table `setup_timers`

Additional output tables maintained, relative to the preceding configuration:

- `mutex_instances`
- `rwlock_instances`
- `cond_instances`
- `file_instances`
- `users`
- `hosts`
- `accounts`
- `socket_summary_by_event_name`
- `file_summary_by_instance`
- `file_summary_by_event_name`
- `objects_summary_global_by_type`
- `memory_summary_global_by_event_name`
- `table_lock_waits_summary_by_table`
- `table_io_waits_summary_by_index_usage`
- `table_io_waits_summary_by_table`
- `events_waits_summary_by_instance`
- `events_waits_summary_global_by_event_name`
- `events_stages_summary_global_by_event_name`
- `events_statements_summary_global_by_event_name`
- `events_transactions_summary_global_by_event_name`

## Global and Thread Instrumentation Only

Server configuration state:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
```

## Example Consumer Configurations

| NAME                        | ENABLED |
|-----------------------------|---------|
| global_instrumentation      | YES     |
| thread_instrumentation      | YES     |
| events_waits_current        | NO      |
| ...                         |         |
| events_stages_current       | NO      |
| ...                         |         |
| events_statements_current   | NO      |
| ...                         |         |
| events_transactions_current | NO      |
| ...                         |         |

In this configuration, instrumentation is maintained globally and per thread. No individual events are collected in the current-events or event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumers `events_xxx_current`, where `xxx` is `waits`, `stages`, `statements`, `transactions`
- Table `setup_actors`
- Column `threads.instrumented`

Additional output tables maintained, relative to the preceding configuration:

- `events_xxx_summary_by_yyy_by_event_name`, where `xxx` is `waits`, `stages`, `statements`, `transactions`; and `yyy` is `thread`, `user`, `host`, `account`

## Global, Thread, and Current-Event Instrumentation

Server configuration state:

| mysql> SELECT * FROM performance_schema.setup_consumers; |         |
|----------------------------------------------------------|---------|
| NAME                                                     | ENABLED |
| global_instrumentation                                   | YES     |
| thread_instrumentation                                   | YES     |
| events_waits_current                                     | YES     |
| events_waits_history                                     | NO      |
| events_waits_history_long                                | NO      |
| events_stages_current                                    | YES     |
| events_stages_history                                    | NO      |
| events_stages_history_long                               | NO      |
| events_statements_current                                | YES     |
| events_statements_history                                | NO      |
| events_statements_history_long                           | NO      |
| events_transactions_current                              | YES     |
| events_transactions_history                              | NO      |
| events_transactions_history_long                         | NO      |
| ...                                                      |         |

In this configuration, instrumentation is maintained globally and per thread. Individual events are collected in the current-events table, but not in the event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Consumers `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`, `transactions`
- Consumers `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

Additional output tables maintained, relative to the preceding configuration:

- `events_xxx_current`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

## Global, Thread, Current-Event, and Event-History instrumentation

The preceding configuration collects no event history because the `events_xxx_history` and `events_xxx_history_long` consumers are disabled. Those consumers can be enabled separately or together to collect event history per thread, globally, or both.

This configuration collects event history per thread, but not globally:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
| NAME | ENABLED |
+-----+-----+
| global_instrumentation | YES |
| thread_instrumentation | YES |
| events_waits_current | YES |
| events_waits_history | YES |
| events_waits_history_long | NO |
| events_stages_current | YES |
| events_stages_history | YES |
| events_stages_history_long | NO |
| events_statements_current | YES |
| events_statements_history | YES |
| events_statements_history_long | NO |
| events_transactions_current | YES |
| events_transactions_history | YES |
| events_transactions_history_long | NO |
| ... | |
+-----+-----+
```

Event-history tables maintained for this configuration:

- `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

This configuration collects event history globally, but not per thread:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
| NAME | ENABLED |
+-----+-----+
| global_instrumentation | YES |
| thread_instrumentation | YES |
| events_waits_current | YES |
| events_waits_history | NO |
| events_waits_history_long | YES |
| events_stages_current | YES |
| events_stages_history | NO |
| events_stages_history_long | YES |
| events_statements_current | YES |
| events_statements_history | NO |
| events_statements_history_long | YES |
| events_transactions_current | YES |
| events_transactions_history | NO |
| events_transactions_history_long | YES |
| ... | |
+-----+-----+
```

Event-history tables maintained for this configuration:

- `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

This configuration collects event history per thread and globally:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
| NAME | ENABLED |
+-----+-----+
| global_instrumentation | YES |
| thread_instrumentation | YES |
| events_waits_current | YES |
| events_waits_history | YES |
| ... | |
+-----+-----+
```

|                                  |     |
|----------------------------------|-----|
| events_waits_history_long        | YES |
| events_stages_current            | YES |
| events_stages_history            | YES |
| events_stages_history_long       | YES |
| events_statements_current        | YES |
| events_statements_history        | YES |
| events_statements_history_long   | YES |
| events_transactions_current      | YES |
| events_transactions_history      | YES |
| events_transactions_history_long | YES |
| ...                              |     |

Event-history tables maintained for this configuration:

- `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`, `transactions`
- `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

## 25.4.9 Naming Instruments or Consumers for Filtering Operations

Names given for filtering operations can be as specific or general as required. To indicate a single instrument or consumer, specify its name in full:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME = 'wait/synch/mutex/myisammrg/MYRG_INFO::mutex';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME = 'events_waits_current';
```

To specify a group of instruments or consumers, use a pattern that matches the group members:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME LIKE 'wait/synch/mutex/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE '%history%';
```

If you use a pattern, it should be chosen so that it matches all the items of interest and no others. For example, to select all file I/O instruments, it is better to use a pattern that includes the entire instrument name prefix:

```
... WHERE NAME LIKE 'wait/io/file/%';
```

The pattern '`%/file/%`' matches other instruments that have an element of '`/file/`' anywhere in the name. Even less suitable is the pattern '`%file%`' because it matches instruments with '`file`' anywhere in the name, such as `wait/synch/mutex/innodb/file_open_mutex`.

To check which instrument or consumer names a pattern matches, perform a simple test:

```
SELECT NAME FROM performance_schema.setup_instruments
WHERE NAME LIKE 'pattern';

SELECT NAME FROM performance_schema.setup_consumers
WHERE NAME LIKE 'pattern';
```

For information about the types of names that are supported, see [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

## 25.4.10 Determining What Is Instrumented

It is always possible to determine what instruments the Performance Schema includes by checking the `setup_instruments` table. For example, to see what file-related events are instrumented for the InnoDB storage engine, use this query:

```
mysql> SELECT * FROM performance_schema.setup_instruments
 WHERE NAME LIKE 'wait/io/file/innodb/%';
+-----+-----+-----+
| NAME | ENABLED | TIMED |
+-----+-----+-----+
| wait/io/file/innodb/innodb_data_file | YES | YES |
| wait/io/file/innodb/innodb_log_file | YES | YES |
| wait/io/file/innodb/innodb_temp_file | YES | YES |
+-----+-----+-----+
```

An exhaustive description of precisely what is instrumented is not given in this documentation, for several reasons:

- What is instrumented is the server code. Changes to this code occur often, which also affects the set of instruments.
- It is not practical to list all the instruments because there are hundreds of them.
- As described earlier, it is possible to find out by querying the `setup_instruments` table. This information is always up to date for your version of MySQL, also includes instrumentation for instrumented plugins you might have installed that are not part of the core server, and can be used by automated tools.

## 25.5 Performance Schema Queries

Pre-filtering limits which event information is collected and is independent of any particular user. By contrast, post-filtering is performed by individual users through the use of queries with appropriate `WHERE` clauses that restrict what event information to select from the events available after pre-filtering has been applied.

In [Section 25.4.3, “Event Pre-Filtering”](#), an example showed how to pre-filter for file instruments. If the event tables contain both file and nonfile information, post-filtering is another way to see information only for file events. Add a `WHERE` clause to queries to restrict event selection appropriately:

```
mysql> SELECT THREAD_ID, NUMBER_OF_BYTES
 FROM performance_schema.events_waits_history
 WHERE EVENT_NAME LIKE 'wait/io/file/%'
 AND NUMBER_OF_BYTES IS NOT NULL;
+-----+-----+
| THREAD_ID | NUMBER_OF_BYTES |
+-----+-----+
| 11 | 66 |
| 11 | 47 |
| 11 | 139 |
| 5 | 24 |
| 5 | 834 |
+-----+-----+
```

## 25.6 Performance Schema Instrument Naming Conventions

An instrument name consists of a sequence of elements separated by ‘/’ characters. Example names:

```
wait/io/file/myisam/log
wait/io/file/mysys/charset
wait/lock/table/sql/handler
wait/synch/cond/mysys/COND_alarm
wait/synch/cond/sql/BINLOG::update_cond
wait/synch/mutex/mysys/BITMAP_mutex
wait/synch/mutex/sql/LOCK_delete
wait/synch/rwlock/sql/Query_cache_query::lock
stage/sql/closing tables
stage/sql/Sorting result
statement/com/Execute
statement/com/Query
statement/sql/create_table
```

```
statement/sql/lock_tables
```

The instrument name space has a tree-like structure. The elements of an instrument name from left to right provide a progression from more general to more specific. The number of elements a name has depends on the type of instrument.

The interpretation of a given element in a name depends on the elements to the left of it. For example, `myisam` appears in both of the following names, but `myisam` in the first name is related to file I/O, whereas in the second it is related to a synchronization instrument:

```
wait/io/file/myisam/log
wait/synch/cond/myisam/MI_SORT_INFO::cond
```

Instrument names consist of a prefix with a structure defined by the Performance Schema implementation and a suffix defined by the developer implementing the instrument code. The top-level element of an instrument prefix indicates the type of instrument. This element also determines which event timer in the `setup_timers` table applies to the instrument. For the prefix part of instrument names, the top level indicates the type of instrument.

The suffix part of instrument names comes from the code for the instruments themselves. Suffixes may include levels such as these:

- A name for the major element (a server module such as `myisam`, `innodb`, `mysys`, or `sql`) or a plugin name.
- The name of a variable in the code, in the form `XXX` (a global variable) or `CCC::MMM` (a member `MMM` in class `CCC`). Examples: `COND_thread_cache`, `THR_LOCK_myisam`, `BINLOG::LOCK_index`.
- [Top-Level Instrument Elements](#)
- [Idle Instrument Elements](#)
- [Memory Instrument Elements](#)
- [Stage Instrument Elements](#)
- [Statement Instrument Elements](#)
- [Wait Instrument Elements](#)

## Top-Level Instrument Elements

- `idle`: An instrumented idle event. This instrument has no further elements.
- `memory`: An instrumented memory event.
- `stage`: An instrumented stage event.
- `statement`: An instrumented statement event.
- `transaction`: An instrumented transaction event. This instrument has no further elements.
- `wait`: An instrumented wait event.

## Idle Instrument Elements

The `idle` instrument is used for idle events, which The Performance Schema generates as discussed in the description of the `socket_instances.STATE` column in [Section 25.12.3.5, “The socket\\_instances Table”](#).

## Memory Instrument Elements

Most memory instrumentation is disabled by default, and can be enabled or disabled at startup, or dynamically at runtime by updating the `ENABLED` column of the relevant

instruments in the `setup_instruments` table. Memory instruments have names of the form `memory/code_area/instrument_name` where `code_area` is a value such as `sql` or `myisam`, and `instrument_name` is the instrument detail.

Instruments named with the prefix `memory/performance_schema/` expose how much memory is allocated for internal buffers in the Performance Schema. The `memory/performance_schema/` instruments are built in, always enabled, and cannot be disabled at startup or runtime. Built-in memory instruments are displayed only in the `memory_summary_global_by_event_name` table. For more information, see [Section 25.17, “The Performance Schema Memory-Allocation Model”](#).

## Stage Instrument Elements

Stage instruments have names of the form `stage/code_area/stage_name`, where `code_area` is a value such as `sql` or `myisam`, and `stage_name` indicates the stage of statement processing, such as `Sorting result` or `Sending data`. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table.

## Statement Instrument Elements

- `statement/abstract/*`: An abstract instrument for statement operations. Abstract instruments are used during the early stages of statement classification before the exact statement type is known, then changed to a more specific statement instrument when the type is known. For a description of this process, see [Section 25.12.6, “Performance Schema Statement Event Tables”](#).
- `statement/com`: An instrumented command operation. These have names corresponding to `COM_xxx` operations (see the `mysql_com.h` header file and `sql/sql_parse.cc`. For example, the `statement/com/Connect` and `statement/com/Init_DB` instruments correspond to the `COM_CONNECT` and `COM_INIT_DB` commands.
- `statement/scheduler/event`: A single instrument to track all events executed by the Event Scheduler. This instrument comes into play when a scheduled event begins executing.
- `statement/sp`: An instrumented internal instruction executed by a stored program. For example, the `statement/sp/cfetch` and `statement/sp/freturn` instruments are used cursor fetch and function return instructions.
- `statement/sql`: An instrumented SQL statement operation. For example, the `statement/sql/create_db` and `statement/sql/select` instruments are used for `CREATE DATABASE` and `SELECT` statements.

## Wait Instrument Elements

- `wait/io`

An instrumented I/O operation.

- `wait/io/file`

An instrumented file I/O operation. For files, the wait is the time waiting for the file operation to complete (for example, a call to `fwrite()`). Due to caching, the physical file I/O on the disk might not happen within this call.

- `wait/io/socket`

An instrumented socket operation. Socket instruments have names of the form `wait/io/socket/sql/socket_type`. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcpip_socket` or `server_unix_socket`, respectively. When a listening socket detects a connection, the server transfers the connection to

a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.

- `wait/io/table`

An instrumented table I/O operation. These include row-level accesses to persistent base tables or temporary tables. Operations that affect rows are fetch, insert, update, and delete. For a view, waits are associated with base tables referenced by the view.

Unlike most waits, a table I/O wait can include other waits. For example, table I/O might include file I/O or memory operations. Thus, `events_waits_current` for a table I/O wait usually has two rows. For more information, see [Section 25.8, “Performance Schema Atom and Molecule Events”](#).

Some row operations might cause multiple table I/O waits. For example, an insert might activate a trigger that causes an update.

- `wait/lock`

An instrumented lock operation.

- `wait/lock/table`

An instrumented table lock operation.

- `wait/lock/metadata/sql/mdl`

An instrumented metadata lock operation.

- `wait/synch`

An instrumented synchronization object. For synchronization objects, the `TIMER_WAIT` time includes the amount of time blocked while attempting to acquire a lock on the object, if any.

- `wait/synch/cond`

A condition is used by one thread to signal to other threads that something they were waiting for has happened. If a single thread was waiting for a condition, it can wake up and proceed with its execution. If several threads were waiting, they can all wake up and compete for the resource for which they were waiting.

- `wait/synch/mutex`

A mutual exclusion object used to permit access to a resource (such as a section of executable code) while preventing other threads from accessing the resource.

- `wait/synch/rwlock`

A `read/write lock` object used to lock a specific variable for access while preventing its use by other threads. A shared read lock can be acquired simultaneously by multiple threads. An exclusive write lock can be acquired by only one thread at a time.

- `wait/synch/sxlock`

A shared-exclusive (SX) lock is a type of `rwlock` lock object that provides write access to a common resource while permitting inconsistent reads by other threads. `sxlocks` optimize concurrency and improve scalability for read-write workloads.

## 25.7 Performance Schema Status Monitoring

There are several status variables associated with the Performance Schema:

```
mysql> SHOW STATUS LIKE 'perf%';
```

| Variable_name                                 | Value |
|-----------------------------------------------|-------|
| Performance_schema_accounts_lost              | 0     |
| Performance_schema_cond_classes_lost          | 0     |
| Performance_schema_cond_instances_lost        | 0     |
| Performance_schema_digest_lost                | 0     |
| Performance_schema_file_classes_lost          | 0     |
| Performance_schema_file_handles_lost          | 0     |
| Performance_schema_file_instances_lost        | 0     |
| Performance_schema_hosts_lost                 | 0     |
| Performance_schema_locker_lost                | 0     |
| Performance_schema_memory_classes_lost        | 0     |
| Performance_schema_metadata_lock_lost         | 0     |
| Performance_schema_mutex_classes_lost         | 0     |
| Performance_schema_mutex_instances_lost       | 0     |
| Performance_schema_nested_statement_lost      | 0     |
| Performance_schema_program_lost               | 0     |
| Performance_schema_rwlock_classes_lost        | 0     |
| Performance_schema_rwlock_instances_lost      | 0     |
| Performance_schema_session_connect_attrs_lost | 0     |
| Performance_schema_socket_classes_lost        | 0     |
| Performance_schema_socket_instances_lost      | 0     |
| Performance_schema_stage_classes_lost         | 0     |
| Performance_schema_statement_classes_lost     | 0     |
| Performance_schema_table_handles_lost         | 0     |
| Performance_schema_table_instances_lost       | 0     |
| Performance_schema_thread_classes_lost        | 0     |
| Performance_schema_thread_instances_lost      | 0     |
| Performance_schema_users_lost                 | 0     |

The Performance Schema status variables provide information about instrumentation that could not be loaded or created due to memory constraints. Names for these variables have several forms:

- `Performance_schema_xxx_classes_lost` indicates how many instruments of type `xxx` could not be loaded.
- `Performance_schema_xxx_instances_lost` indicates how many instances of object type `xxx` could not be created.
- `Performance_schema_xxx_handles_lost` indicates how many instances of object type `xxx` could not be opened.
- `Performance_schema_locker_lost` indicates how many events are “lost” or not recorded.

For example, if a mutex is instrumented in the server source but the server cannot allocate memory for the instrumentation at runtime, it increments `Performance_schema_mutex_classes_lost`. The mutex still functions as a synchronization object (that is, the server continues to function normally), but performance data for it is not collected. If the instrument can be allocated, it can be used for initializing instrumented mutex instances. For a singleton mutex such as a global mutex, there is only one instance. Other mutexes have an instance per connection, or per page in various caches and data buffers, so the number of instances varies over time. Increasing the maximum number of connections or the maximum size of some buffers increases the maximum number of instances that might be allocated at once. If the server cannot create a given instrumented mutex instance, it increments `Performance_schema_mutex_instances_lost`.

Suppose that the following conditions hold:

- The server was started with the `--performance_schema_max_mutex_classes=200` option and thus has room for 200 mutex instruments.
- 150 mutex instruments have been loaded already.
- The plugin named `plugin_a` contains 40 mutex instruments.
- The plugin named `plugin_b` contains 20 mutex instruments.

The server allocates mutex instruments for the plugins depending on how many they need and how many are available, as illustrated by the following sequence of statements:

```
INSTALL PLUGIN plugin_a;
```

The server now has  $150+40 = 190$  mutex instruments.

```
UNINSTALL PLUGIN plugin_a;
```

The server still has 190 instruments. All the historical data generated by the plugin code is still available, but new events for the instruments are not collected.

```
INSTALL PLUGIN plugin_a;
```

The server detects that the 40 instruments are already defined, so no new instruments are created, and previously assigned internal memory buffers are reused. The server still has 190 instruments.

```
INSTALL PLUGIN plugin_b;
```

The server has room for  $200-190 = 10$  instruments (in this case, mutex classes), and sees that the plugin contains 20 new instruments. 10 instruments are loaded, and 10 are discarded or “lost.” The `Performance_schema_mutex_classes_lost` indicates the number of instruments (mutex classes) lost:

```
mysql> SHOW STATUS LIKE "perf%mutex_classes_lost";
+-----+-----+
| Variable_name | value |
+-----+-----+
| Performance_schema_mutex_classes_lost | 10 |
+-----+-----+
1 row in set (0.10 sec)
```

The instrumentation still works and collects (partial) data for `plugin_b`.

When the server cannot create a mutex instrument, these results occur:

- No row for the instrument is inserted into the `setup_instruments` table.
- `Performance_schema_mutex_classes_lost` increases by 1.
- `Performance_schema_mutex_instances_lost` does not change. (When the mutex instrument is not created, it cannot be used to create instrumented mutex instances later.)

The pattern just described applies to all types of instruments, not just mutexes.

A value of `Performance_schema_mutex_classes_lost` greater than 0 can happen in two cases:

- To save a few bytes of memory, you start the server with `--performance_schema_max_mutex_classes=N`, where `N` is less than the default value. The default value is chosen to be sufficient to load all the plugins provided in the MySQL distribution, but this can be reduced if some plugins are never loaded. For example, you might choose not to load some of the storage engines in the distribution.
- You load a third-party plugin that is instrumented for the Performance Schema but do not allow for the plugin's instrumentation memory requirements when you start the server. Because it comes from a third party, the instrument memory consumption of this engine is not accounted for in the default value chosen for `performance_schema_max_mutex_classes`.

If the server has insufficient resources for the plugin's instruments and you do not explicitly allocate more using `--performance_schema_max_mutex_classes=N`, loading the plugin leads to starvation of instruments.

If the value chosen for `performance_schema_max_mutex_classes` is too small, no error is reported in the error log and there is no failure at runtime. However, the content of the tables in the `performance_schema` database misses events. The

`Performance_schema_mutex_classes_lost` status variable is the only visible sign to indicate that some events were dropped internally due to failure to create instruments.

If an instrument is not lost, it is known to the Performance Schema, and is used when instrumenting instances. For example, `wait/synch/mutex/sql/LOCK_delete` is the name of a mutex instrument in the `setup_instruments` table. This single instrument is used when creating a mutex in the code (in `THD::LOCK_delete`) however many instances of the mutex are needed as the server runs. In this case, `LOCK_delete` is a mutex that is per connection (`THD`), so if a server has 1000 connections, there are 1000 threads, and 1000 instrumented `LOCK_delete` mutex instances (`THD::LOCK_delete`).

If the server does not have room for all these 1000 instrumented mutexes (instances), some mutexes are created with instrumentation, and some are created without instrumentation. If the server can create only 800 instances, 200 instances are lost. The server continues to run, but increments `Performance_schema_mutex_instances_lost` by 200 to indicate that instances could not be created.

A value of `Performance_schema_mutex_instances_lost` greater than 0 can happen when the code initializes more mutexes at runtime than were allocated for `--performance_schema_max_mutex_instances=N`.

The bottom line is that if `SHOW STATUS LIKE 'perf%'` says that nothing was lost (all values are zero), the Performance Schema data is accurate and can be relied upon. If something was lost, the data is incomplete, and the Performance Schema could not record everything given the insufficient amount of memory it was given to use. In this case, the specific `Performance_schema_xxx_lost` variable indicates the problem area.

It might be appropriate in some cases to cause deliberate instrument starvation. For example, if you do not care about performance data for file I/O, you can start the server with all Performance Schema parameters related to file I/O set to 0. No memory is allocated for file-related classes, instances, or handles, and all file events are lost.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...
***** 3. row *****
 Type: performance_schema
 Name: events_waits_history.size
Status: 76
***** 4. row *****
 Type: performance_schema
 Name: events_waits_history.count
Status: 10000
***** 5. row *****
 Type: performance_schema
 Name: events_waits_history.memory
Status: 760000
...
***** 57. row *****
 Type: performance_schema
 Name: performance_schema.memory
Status: 26459600
...
```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements. For a description of the field meanings, see [Section 13.7.5.15, "SHOW ENGINE Statement"](#).

## 25.8 Performance Schema Atom and Molecule Events

For a table I/O event, there are usually two rows in `events_waits_current`, not one. For example, a row fetch might result in rows like this:

| Row# | EVENT_NAME                | TIMER_START | TIMER_END |
|------|---------------------------|-------------|-----------|
| 1    | wait/io/file/myisam/dfile | 10001       | 10002     |
| 2    | wait/io/table/sql/handler | 10000       | NULL      |

The row fetch causes a file read. In the example, the table I/O fetch event started before the file I/O event but has not finished (its `TIMER_END` value is `NULL`). The file I/O event is “nested” within the table I/O event.

This occurs because, unlike other “atomic” wait events such as for mutexes or file I/O, table I/O events are “molecular” and include (overlap with) other events. In `events_waits_current`, the table I/O event usually has two rows:

- One row for the most recent table I/O wait event
- One row for the most recent wait event of any kind

Usually, but not always, the “of any kind” wait event differs from the table I/O event. As each subsidiary event completes, it disappears from `events_waits_current`. At this point, and until the next subsidiary event begins, the table I/O wait is also the most recent wait of any kind.

## 25.9 Performance Schema Tables for Current and Historical Events

For wait, stage, statement, and transaction events, the Performance Schema can monitor and store current events. In addition, when events end, the Performance Schema can store them in history tables. For each event type, the Performance Schema uses three tables for storing current and historical events. The tables have names of the following forms, where `xxx` indicates the event type (`waits`, `stages`, `statements`, `transactions`):

- `events_xxx_current`: The “current events” table stores the current monitored event for each thread (one row per thread).
- `events_xxx_history`: The “recent history” table stores the most recent events that have ended per thread (up to a maximum number of rows per thread).
- `events_xxx_history_long`: The “long history” table stores the most recent events that have ended globally (across all threads, up to a maximum number of rows per table).

The `_current` table for each event type contains one row per thread, so there is no system variable for configuring its maximum size. The Performance Schema autosizes the history tables, or the sizes can be configured explicitly at server startup using table-specific system variables, as indicated in the sections that describe the individual history tables. Typical autosized values are 10 rows per thread for `_history` tables, and 10,000 rows total for `_history_long` tables.

For each event type, the `_current`, `_history`, and `_history_long` tables have the same columns.

The `_current` tables show what is currently happening within the server. When a current event ends, it is removed from its `_current` table.

The `_history` and `_history_long` tables show what has happened in the recent past. When the history tables become full, old events are discarded as new events are added. Rows expire from the `_history` and `_history_long` tables in different ways because the tables serve different purposes:

- `_history` is meant to investigate individual threads, independently of the global server load.
- `_history_long` is meant to investigate the server globally, not each thread.

The difference between the two types of history tables relates to the data retention policy. Both tables contain the same data when an event is first seen. However, data within each table expires differently over time, so that data might be preserved for a longer or shorter time in each table:

- For `_history`, when the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added.
- For `_history_long`, when the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

When a thread ends, all its rows are discarded from the `_history` table but not from the `_history_long` table.

The following example illustrates the differences in how events are added to and discarded from the two types of history tables. The principles apply equally to all event types. The example is based on these assumptions:

- The Performance Schema is configured to retain 10 rows per thread in the `_history` table and 10,000 rows total in the `_history_long` table.
- Thread A generates 1 event per second.

Thread B generates 100 events per second.

- No other threads are running.

After 5 seconds of execution:

- A and B have generated 5 and 500 events, respectively.
- `_history` contains 5 rows for A and 10 rows for B. Because storage per thread is limited to 10 rows, no rows have been discarded for A, whereas 490 rows have been discarded for B.
- `_history_long` contains 5 rows for A and 500 rows for B. Because the table has a maximum size of 10,000 rows, no rows have been discarded for either thread.

After 5 minutes (300 seconds) of execution:

- A and B have generated 300 and 30,000 events, respectively.
- `_history` contains 10 rows for A and 10 rows for B. Because storage per thread is limited to 10 rows, 290 rows have been discarded for A, whereas 29,990 rows have been discarded for B. Rows for A include data up to 10 seconds old, whereas rows for B include data up to only .1 seconds old.
- `_history_long` contains 10,000 rows. Because A and B together generate 101 events per second, the table contains data up to approximately  $10,000/101 = 99$  seconds old, with a mix of rows approximately 100 to 1 from B as opposed to A.

## 25.10 Performance Schema Statement Digests

The MySQL server is capable of maintaining statement digest information. The digesting process converts each SQL statement to normalized form (the statement digest) and computes an MD5 hash value (the digest hash value) from the normalized result. Normalization permits statements that are similar to be grouped and summarized to expose information about the types of statements the server is executing and how often they occur. This section describes how statement digesting occurs and how it can be useful.

Digesting occurs in the parser regardless of whether the Performance Schema is available, so that other server components such as MySQL Enterprise Firewall and query rewrite plugins have access to statement digests.

- [Statement Digest General Concepts](#)
- [Statement Digests in the Performance Schema](#)

- Statement Digest Memory Use

## Statement Digest General Concepts

When the parser receives an SQL statement, it computes a statement digest if that digest is needed, which is true if any of the following conditions are true:

- Performance Schema digest instrumentation is enabled
- MySQL Enterprise Firewall is enabled
- A Query Rewrite Plugin is enabled

The `max_digest_length` system variable value determines the maximum number of bytes available per session for computation of normalized statement digests. Once that amount of space is used during digest computation, truncation occurs: no further tokens from a parsed statement are collected or figure into its digest value. Statements that differ only after that many bytes of parsed tokens produce the same normalized statement digest and are considered identical if compared or if aggregated for digest statistics.

### Warning

Setting the `max_digest_length` system variable to zero disables digest production, which also disables server functionality that requires digests.

After the normalized statement has been computed, an MD5 hash value is computed from it. In addition:

- If MySQL Enterprise Firewall is enabled, it is called and the digest as computed is available to it.
- If any Query Rewrite Plugin is enabled, it is called and the statement digest and digest value are available to it.
- If the Performance Schema has digest instrumentation enabled, it makes a copy of the normalized statement digest, allocating a maximum of `performance_schema_max_digest_length` bytes for it. Consequently, if `performance_schema_max_digest_length` is less than `max_digest_length`, the copy is truncated relative to the original. The copy of the normalized statement digest is stored in the appropriate Performance Schema tables, along with the MD5 hash value computed from the original normalized statement. (If the Performance Schema truncates its copy of the normalized statement digest relative to the original, it does not recompute the MD5 hash value.)

Statement normalization transforms the statement text to a more standardized digest string representation that preserves the general statement structure while removing information not essential to the structure:

- Object identifiers such as database and table names are preserved.
- Literal values are converted to parameter markers. A normalized statement does not retain information such as names, passwords, dates, and so forth.
- Comments are removed and whitespace is adjusted.

Consider these statements:

```
SELECT * FROM orders WHERE customer_id=10 AND quantity>20
SELECT * FROM orders WHERE customer_id = 20 AND quantity > 100
```

To normalize these statements, the parser replaces data values by `?` and adjusts whitespace. Both statements yield the same normalized form and thus are considered “the same”:

```
SELECT * FROM orders WHERE customer_id = ? AND quantity > ?
```

The normalized statement contains less information but is still representative of the original statement. Other similar statements that have different data values have the same normalized form.

Now consider these statements:

```
SELECT * FROM customers WHERE customer_id = 1000
SELECT * FROM orders WHERE customer_id = 1000
```

In this case, the normalized statements differ because the object identifiers differ:

```
SELECT * FROM customers WHERE customer_id = ?
SELECT * FROM orders WHERE customer_id = ?
```

If normalization produces a statement that exceeds the space available in the digest buffer (as determined by `max_digest_length`), truncation occurs and the text ends with “...”. Long normalized statements that differ only in the part that occurs following the “...” are considered the same. Consider these statements:

```
SELECT * FROM mytable WHERE cola = 10 AND colb = 20
SELECT * FROM mytable WHERE cola = 10 AND colc = 20
```

If the cutoff happens to be right after the `AND`, both statements have this normalized form:

```
SELECT * FROM mytable WHERE cola = ? AND ...
```

In this case, the difference in the second column name is lost and both statements are considered the same.

## Statement Digests in the Performance Schema

In the Performance Schema, statement digesting involves these elements:

- A `statements_digest` consumer in the `setup_consumers` table controls whether the Performance Schema maintains digest information. See [Statement Digest Consumer](#).
- The statement event tables (`events_statements_current`, `events_statements_history`, and `events_statements_history_long`) have columns for storing normalized statement digests and the corresponding digest MD5 hash values:
  - `DIGEST_TEXT` is the text of the normalized statement digest. This is a copy of the original normalized statement that was computed to a maximum of `max_digest_length` bytes, further truncated as necessary to `performance_schema_max_digest_length` bytes.
  - `DIGEST` is the digest MD5 hash value computed from the original normalized statement.

See [Section 25.12.6, “Performance Schema Statement Event Tables”](#).

- The `events_statements_summary_by_digest` summary table provides aggregated statement digest information. This table aggregates information for statements per `SCHEMA_NAME` and `DIGEST` combination. The Performance Schema uses MD5 hash values for aggregation because they are fast to compute and have a favorable statistical distribution that minimizes collisions. See [Section 25.12.15.3, “Statement Summary Tables”](#).

The statement event tables also have an `SQL_TEXT` column that contains the original SQL statement. The maximum space available for statement display is 1024 bytes by default. To change this value, set the `performance_schema_max_sql_text_length` system variable at server startup.

The `performance_schema_max_digest_length` system variable determines the maximum number of bytes available per statement for digest value storage in the Performance Schema.

However, the display length of statement digests may be longer than the available buffer size due to internal encoding of statement elements such as keywords and literal values. Consequently, values selected from the `DIGEST_TEXT` column of statement event tables may appear to exceed the `performance_schema_max_digest_length` value.

The `events_statements_summary_by_digest` summary table provides a profile of the statements executed by the server. It shows what kinds of statements an application is executing and how often. An application developer can use this information together with other information in the table to assess the application's performance characteristics. For example, table columns that show wait times, lock times, or index use may highlight types of queries that are inefficient. This gives the developer insight into which parts of the application need attention.

The `events_statements_summary_by_digest` summary table has a fixed size. By default the Performance Schema estimates the size to use at startup. To specify the table size explicitly, set the `performance_schema_digests_size` system variable at server startup. If the table becomes full, the Performance Schema groups statements that have `SCHEMA_NAME` and `DIGEST` values not matching existing values in the table in a special row with `SCHEMA_NAME` and `DIGEST` set to `NULL`. This permits all statements to be counted. However, if the special row accounts for a significant percentage of the statements executed, it might be desirable to increase the summary table size by increasing `performance_schema_digests_size`.

## Statement Digest Memory Use

For applications that generate very long statements that differ only at the end, increasing `max_digest_length` enables computation of digests that distinguish statements that would otherwise aggregate to the same digest. Conversely, decreasing `max_digest_length` causes the server to devote less memory to digest storage but increases the likelihood of longer statements aggregating to the same digest. Administrators should keep in mind that larger values result in correspondingly increased memory requirements, particularly for workloads that involve large numbers of simultaneous sessions (the server allocates `max_digest_length` bytes per session).

As described previously, normalized statement digests as computed by the parser are constrained to a maximum of `max_digest_length` bytes, whereas normalized statement digests stored in the Performance Schema use `performance_schema_max_digest_length` bytes. The following memory-use considerations apply regarding the relative values of `max_digest_length` and `performance_schema_max_digest_length`:

- If `max_digest_length` is less than `performance_schema_max_digest_length`:
  - Server components other than the Performance Schema use normalized statement digests that take up to `max_digest_length` bytes.
  - The Performance Schema does not further truncate normalized statement digests that it stores, but allocates more memory than `max_digest_length` bytes per digest, which is unnecessary.
- If `max_digest_length` equals `performance_schema_max_digest_length`:
  - Server components other than the Performance Schema use normalized statement digests that take up to `max_digest_length` bytes.
  - The Performance Schema does not further truncate normalized statement digests that it stores, and allocates the same amount of memory as `max_digest_length` bytes per digest.
- If `max_digest_length` is greater than `performance_schema_max_digest_length`:
  - Server components other than the Performance Schema use normalized statement digests that take up to `max_digest_length` bytes.
  - The Performance Schema further truncates normalized statement digests that it stores, and allocates less memory than `max_digest_length` bytes per digest.

Because the Performance Schema statement event tables might store many digests, setting `performance_schema_max_digest_length` smaller than `max_digest_length` enables administrators to balance these factors:

- The need to have long normalized statement digests available for server components outside the Performance Schema
- Many concurrent sessions, each of which allocates digest-computation memory
- The need to limit memory consumption by the Performance Schema statement event tables when storing many statement digests

The `performance_schema_max_digest_length` setting is not per session, it is per statement, and a session can store multiple statements in the `events_statements_history` table. A typical number of statements in this table is 10 per session, so each session consumes 10 times the memory indicated by the `performance_schema_max_digest_length` value, for this table alone.

Also, there are many statements (and digests) collected globally, most notably in the `events_statements_history_long` table. Here, too, `N` statements stored consume `N` times the memory indicated by the `performance_schema_max_digest_length` value.

To assess the amount of memory used for SQL statement storage and digest computation, use the `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` statement, or monitor these instruments:

```
mysql> SELECT NAME
 FROM performance_schema.setup_instruments
 WHERE NAME LIKE '%.sqltext';
+-----+
| NAME |
+-----+
| memory/performance_schema/events_statements_history.sqltext |
| memory/performance_schema/events_statements_current.sqltext |
| memory/performance_schema/events_statements_history_long.sqltext |
+-----+

mysql> SELECT NAME
 FROM performance_schema.setup_instruments
 WHERE NAME LIKE 'memory/performance_schema%.*tokens';
+-----+
| NAME |
+-----+
| memory/performance_schema/events_statements_history.tokens |
| memory/performance_schema/events_statements_current.tokens |
| memory/performance_schema/events_statements_summary_by_digest.tokens |
| memory/performance_schema/events_statements_history_long.tokens |
+-----+
```

## 25.11 Performance Schema General Table Characteristics

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

Many tables in the `performance_schema` database are read only and cannot be modified:

```
mysql> TRUNCATE TABLE performance_schema.setup_instruments;
ERROR 1683 (HY000): Invalid performance_schema usage.
```

Some of the setup tables have columns that can be modified to affect Performance Schema operation; some also permit rows to be inserted or deleted. Truncation is permitted to clear collected events, so `TRUNCATE TABLE` can be used on tables containing those kinds of information, such as tables named with a prefix of `events_waits_`.

Summary tables can be truncated with `TRUNCATE TABLE`. Generally, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and

restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

Privileges are as for other databases and tables:

- To retrieve from `performance_schema` tables, you must have the `SELECT` privilege.
- To change those columns that can be modified, you must have the `UPDATE` privilege.
- To truncate tables that can be truncated, you must have the `DROP` privilege.

Because only a limited set of privileges apply to Performance Schema tables, attempts to use `GRANT ALL` as shorthand for granting privileges at the database or table level fail with an error:

```
mysql> GRANT ALL ON performance_schema.*
 TO 'u1'@'localhost';
ERROR 1044 (42000): Access denied for user 'root'@'localhost'
to database 'performance_schema'
mysql> GRANT ALL ON performance_schema.setup_instruments
 TO 'u2'@'localhost';
ERROR 1044 (42000): Access denied for user 'root'@'localhost'
to database 'performance_schema'
```

Instead, grant exactly the desired privileges:

```
mysql> GRANT SELECT ON performance_schema.*
 TO 'u1'@'localhost';
Query OK, 0 rows affected (0.03 sec)

mysql> GRANT SELECT, UPDATE ON performance_schema.setup_instruments
 TO 'u2'@'localhost';
Query OK, 0 rows affected (0.02 sec)
```

## 25.12 Performance Schema Table Descriptions

Tables in the `performance_schema` database can be grouped as follows:

- Setup tables. These tables are used to configure and display monitoring characteristics.
- Current events tables. The `events_waits_current` table contains the most recent event for each thread. Other similar tables contain current events at different levels of the event hierarchy: `events_stages_current` for stage events, `events_statements_current` for statement events, and `events_transactions_current` for transaction events.
- History tables. These tables have the same structure as the current events tables, but contain more rows. For example, for wait events, `events_waits_history` table contains the most recent 10 events per thread. `events_waits_history_long` contains the most recent 10,000 events. Other similar tables exist for stage, statement, and transaction histories.

To change the sizes of the history tables, set the appropriate system variables at server startup. For example, to set the sizes of the wait event history tables, set `performance_schema_events_waits_history_size` and `performance_schema_events_waits_history_long_size`.

- Summary tables. These tables contain information aggregated over groups of events, including those that have been discarded from the history tables.
- Instance tables. These tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information.
- Miscellaneous tables. These do not fall into any of the other table groups.

### 25.12.1 Performance Schema Table Reference

The following table summarizes all available Performance Schema tables. For greater detail, see the individual table descriptions.

**Table 25.1 Performance Schema Tables**

| Name                                                 | Description                                     | Deprecated |
|------------------------------------------------------|-------------------------------------------------|------------|
| accounts                                             | Connection statistics per client account        |            |
| cond_instances                                       | Synchronization object instances                |            |
| events_stages_current                                | Current stage events                            |            |
| events_stages_history                                | Most recent stage events per thread             |            |
| events_stages_history_overall                        | Most recent stage events overall                |            |
| events_stages_summary_by_account_by_event_name       | Stage events per account and event name         |            |
| events_stages_summary_by_host_by_event_name          | Stage events per host name and event name       |            |
| events_stages_summary_by_thread_by_event_name        | Stage waits per thread and event name           |            |
| events_stages_summary_by_user_by_event_name          | Stage events per user name and event name       |            |
| events_stages_summary_by_event_name                  | Stage waits per event name                      |            |
| events_statements_current                            | Current statement events                        |            |
| events_statements_history                            | Most recent statement events per thread         |            |
| events_statements_history_overall                    | Most recent statement events overall            |            |
| events_statements_summary_by_account_by_event_name   | Statement events per account and event name     |            |
| events_statements_summary_by_digest                  | Statement events per schema and digest value    |            |

| <code>users</code>                                 | Connection statistics per client user name |            |
| <code>variables_by_thread</code>                   | Session system variables per session       |            |

## 25.12.2 Performance Schema Setup Tables

The setup tables provide information about the current instrumentation and enable the monitoring configuration to be changed. For this reason, some columns in these tables can be changed if you have the `UPDATE` privilege.

The use of tables rather than individual variables for setup information provides a high degree of flexibility in modifying Performance Schema configuration. For example, you can use a single statement with standard SQL syntax to make multiple simultaneous configuration changes.

These setup tables are available:

- `setup_actors`: How to initialize monitoring for new foreground threads
- `setup_consumers`: The destinations to which event information can be sent and stored
- `setup_instruments`: The classes of instrumented objects for which events can be collected
- `setup_objects`: Which objects should be monitored
- `setup_timers`: The current event timer

### 25.12.2.1 The `setup_actors` Table

The `setup_actors` table contains information that determines whether to enable monitoring and historical event logging for new foreground server threads (threads associated with client connections). This table has a maximum size of 100 rows by default. To change the table size, modify the `performance_schema_setup_actors_size` system variable at server startup.

For each new foreground thread, the Performance Schema matches the user and host for the thread against the rows of the `setup_actors` table. If a row from that table matches, its `ENABLED` and `HISTORY` column values are used to set the `INSTRUMENTED` and `HISTORY` columns, respectively, of the `threads` table row for the thread. This enables instrumenting and historical event logging to be applied selectively per host, user, or account (user and host combination). If there is no match, the `INSTRUMENTED` and `HISTORY` columns for the thread are set to `NO`.

For background threads, there is no associated user. `INSTRUMENTED` and `HISTORY` are `YES` by default and `setup_actors` is not consulted.

The initial contents of the `setup_actors` table match any user and host combination, so monitoring and historical event collection are enabled by default for all foreground threads:

```
mysql> SELECT * FROM performance_schema.setup_actors;
+-----+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+-----+
| % | % | % | YES | YES |
+-----+-----+-----+-----+-----+
```

For information about how to use the `setup_actors` table to affect event monitoring, see [Section 25.4.6, “Pre-Filtering by Thread”](#).

Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the `INSTRUMENTED` and `HISTORY` columns of `threads` table rows.

The `setup_actors` table has these columns:

- `HOST`

The host name. This should be a literal name, or '`%`' to mean "any host."

- `USER`

The user name. This should be a literal name, or '`%`' to mean "any user."

- `ROLE`

Unused.

- `ENABLED`

Whether to enable instrumentation for foreground threads matched by the row. The value is `YES` or `NO`.

- `HISTORY`

Whether to log historical events for foreground threads matched by the row. The value is `YES` or `NO`.

`TRUNCATE TABLE` is permitted for the `setup_actors` table. It removes the rows.

### 25.12.2.2 The `setup_consumers` Table

The `setup_consumers` table lists the types of consumers for which event information can be stored and which are enabled:

| NAME                             | ENABLED |
|----------------------------------|---------|
| events_stages_current            | NO      |
| events_stages_history            | NO      |
| events_stages_history_long       | NO      |
| events_statements_current        | YES     |
| events_statements_history        | YES     |
| events_statements_history_long   | NO      |
| events_transactions_current      | NO      |
| events_transactions_history      | NO      |
| events_transactions_history_long | NO      |
| events_waits_current             | NO      |
| events_waits_history             | NO      |
| events_waits_history_long        | NO      |
| global_instrumentation           | YES     |
| thread_instrumentation           | YES     |
| statements_digest                | YES     |

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. For detailed information about the effect of enabling different consumers, see [Section 25.4.7, “Pre-Filtering by Consumer”](#).

Modifications to the `setup_consumers` table affect monitoring immediately.

The `setup_consumers` table has these columns:

- **NAME**

The consumer name.

- **ENABLED**

Whether the consumer is enabled. The value is **YES** or **NO**. This column can be modified. If you disable a consumer, the server does not spend time adding event information to it.

`TRUNCATE TABLE` is not permitted for the `setup_consumers` table.

### 25.12.2.3 The `setup_instruments` Table

The `setup_instruments` table lists classes of instrumented objects for which events can be collected:

| NAME                                              | ENABLED | TIMED |
|---------------------------------------------------|---------|-------|
| stage/sql/end                                     | NO      | NO    |
| stage/sql/executing                               | NO      | NO    |
| stage/sql/init                                    | NO      | NO    |
| stage/sql/insert                                  | NO      | NO    |
| ...                                               |         |       |
| statement/sql/load                                | YES     | YES   |
| statement/sql/grant                               | YES     | YES   |
| statement/sql/check                               | YES     | YES   |
| statement/sql/flush                               | YES     | YES   |
| ...                                               |         |       |
| wait/synch/mutex/sql/LOCK_global_read_lock        | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db                 | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager                 | YES     | YES   |
| ...                                               |         |       |
| wait/synch/rwlock/sql/LOCK_grant                  | YES     | YES   |
| wait/synch/rwlock/sql/LOGGER::LOCK_logger         | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_connect       | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_slave         | YES     | YES   |
| ...                                               |         |       |
| wait/io/file/sql/binlog                           | YES     | YES   |
| wait/io/file/sql/binlog_index                     | YES     | YES   |
| wait/io/file/sql/casetest                         | YES     | YES   |
| wait/io/file/sql/dbopt                            | YES     | YES   |
| ...                                               |         |       |

Each instrument added to the source code provides a row for the `setup_instruments` table, even when the instrumented code is not executed. When an instrument is enabled and executed, instrumented instances are created, which are visible in the `xxx_instances` tables, such as `file_instances` or `rwlock_instances`.

Modifications to most `setup_instruments` rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

For more information about the role of the `setup_instruments` table in event filtering, see [Section 25.4.3, “Event Pre-Filtering”](#).

The `setup_instruments` table has these columns:

- **NAME**

The instrument name. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 25.6, “Performance Schema Instrument Naming Conventions”](#). Events produced from

execution of an instrument have an `EVENT_NAME` value that is taken from the instrument `NAME` value. (Events do not really have a “name,” but this provides a way to associate events with instruments.)

- **`ENABLED`**

Whether the instrument is enabled. The value is `YES` or `NO`. A disabled instrument produces no events. This column can be modified, although setting `ENABLED` has no effect for instruments that have already been created.

- **`TIMED`**

Whether the instrument is timed. The value is `YES` or `NO`. This column can be modified, although setting `TIMED` has no effect for instruments that have already been created.

For memory instruments, the `TIMED` column in `setup_instruments` is ignored because memory operations are not timed.

If an enabled instrument is not timed, the instrument code is enabled, but the timer is not. Events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

`TRUNCATE TABLE` is not permitted for the `setup_instruments` table.

#### 25.12.2.4 The `setup_objects` Table

The `setup_objects` table controls whether the Performance Schema monitors particular objects. This table has a maximum size of 100 rows by default. To change the table size, modify the `performance_schema_setup_objects_size` system variable at server startup.

The initial `setup_objects` contents look like this:

| OBJECT_TYPE | OBJECT_SCHEMA      | OBJECT_NAME | ENABLED | TIMED |
|-------------|--------------------|-------------|---------|-------|
| EVENT       | mysql              | %           | NO      | NO    |
| EVENT       | performance_schema | %           | NO      | NO    |
| EVENT       | information_schema | %           | NO      | NO    |
| EVENT       | %                  | %           | YES     | YES   |
| FUNCTION    | mysql              | %           | NO      | NO    |
| FUNCTION    | performance_schema | %           | NO      | NO    |
| FUNCTION    | information_schema | %           | NO      | NO    |
| FUNCTION    | %                  | %           | YES     | YES   |
| PROCEDURE   | mysql              | %           | NO      | NO    |
| PROCEDURE   | performance_schema | %           | NO      | NO    |
| PROCEDURE   | information_schema | %           | NO      | NO    |
| PROCEDURE   | %                  | %           | YES     | YES   |
| TABLE       | mysql              | %           | NO      | NO    |
| TABLE       | performance_schema | %           | NO      | NO    |
| TABLE       | information_schema | %           | NO      | NO    |
| TABLE       | %                  | %           | YES     | YES   |
| TRIGGER     | mysql              | %           | NO      | NO    |
| TRIGGER     | performance_schema | %           | NO      | NO    |
| TRIGGER     | information_schema | %           | NO      | NO    |
| TRIGGER     | %                  | %           | YES     | YES   |

Modifications to the `setup_objects` table affect object monitoring immediately.

For object types listed in `setup_objects`, the Performance Schema uses the table to how to monitor them. Object matching is based on the `OBJECT_SCHEMA` and `OBJECT_NAME` columns. Objects for which there is no match are not monitored.

The effect of the default object configuration is to instrument all tables except those in the `mysql`, `INFORMATION_SCHEMA`, and `performance_schema` databases. (Tables in

the `INFORMATION_SCHEMA` database are not instrumented regardless of the contents of `setup_objects`; the row for `information_schema.%` simply makes this default explicit.)

When the Performance Schema checks for a match in `setup_objects`, it tries to find more specific matches first. For example, with a table `db1.t1`, it looks for a match for '`db1`' and '`t1`', then for '`db1`' and '`%`', then for '`%`' and '`%`'. The order in which matching occurs matters because different matching `setup_objects` rows can have different `ENABLED` and `TIMED` values.

Rows can be inserted into or deleted from `setup_objects` by users with the `INSERT` or `DELETE` privilege on the table. For existing rows, only the `ENABLED` and `TIMED` columns can be modified, by users with the `UPDATE` privilege on the table.

For more information about the role of the `setup_objects` table in event filtering, see [Section 25.4.3, “Event Pre-Filtering”](#).

The `setup_objects` table has these columns:

- **`OBJECT_TYPE`**

The type of object to instrument. The value is one of '`EVENT`' (Event Scheduler event), '`FUNCTION`' (stored function), '`PROCEDURE`' (stored procedure), '`TABLE`' (base table), or '`TRIGGER`' (trigger).

`TABLE` filtering affects table I/O events (`wait/io/table/sql/handler` instrument) and table lock events (`wait/lock/table/sql/handler` instrument).

- **`OBJECT_SCHEMA`**

The schema that contains the object. This should be a literal name, or '`%`' to mean "any schema."

- **`OBJECT_NAME`**

The name of the instrumented object. This should be a literal name, or '`%`' to mean "any object."

- **`ENABLED`**

Whether events for the object are instrumented. The value is `YES` or `NO`. This column can be modified.

- **`TIMED`**

Whether events for the object are timed. The value is `YES` or `NO`. This column can be modified.

`TRUNCATE TABLE` is permitted for the `setup_objects` table. It removes the rows.

### 25.12.2.5 The `setup_timers` Table

The `setup_timers` table shows the currently selected event timers:

```
mysql> SELECT * FROM performance_schema.setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| idle | MICROSECOND |
| wait | CYCLE |
| stage | NANOSECOND |
| statement | NANOSECOND |
| transaction | NANOSECOND |
+-----+-----+
```

#### Note

As of MySQL 5.7.21, the Performance Schema `setup_timers` table is deprecated and is removed in MySQL 8.0, as is the `TICKS` row in the `performance_timers` table.

The `setup_timers.TIMER_NAME` value can be changed to select a different timer. The value can be any of the values in the `performance_timers.TIMER_NAME` column. For an explanation of how event timing occurs, see [Section 25.4.1, “Performance Schema Event Timing”](#).

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time. To avoid unpredictable results after you make timer changes, use `TRUNCATE TABLE` to reset Performance Schema statistics.

The `setup_timers` table has these columns:

- `NAME`

The type of instrument the timer is used for.

- `TIMER_NAME`

The timer that applies to the instrument type. This column can be modified.

`TRUNCATE TABLE` is not permitted for the `setup_timers` table.

## 25.12.3 Performance Schema Instance Tables

Instance tables document what types of objects are instrumented. They provide event names and explanatory notes or status information:

- `cond_instances`: Condition synchronization object instances
- `file_instances`: File instances
- `mutex_instances`: Mutex synchronization object instances
- `rwlock_instances`: Lock synchronization object instances
- `socket_instances`: Active connection instances

These tables list instrumented synchronization objects, files, and connections. There are three types of synchronization objects: `cond`, `mutex`, and `rwlock`. Each instance table has an `EVENT_NAME` or `NAME` column to indicate the instrument associated with each row. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

The `mutex_instances.LOCKED_BY_THREAD_ID` and `rwlock_instances.WRITE_LOCKED_BY_THREAD_ID` columns are extremely important for investigating performance bottlenecks or deadlocks. For examples of how to use them for this purpose, see [Section 25.19, “Using the Performance Schema to Diagnose Problems”](#).

### 25.12.3.1 The `cond_instances` Table

The `cond_instances` table lists all the conditions seen by the Performance Schema while the server executes. A condition is a synchronization mechanism used in the code to signal that a specific event has happened, so that a thread waiting for this condition can resume work.

When a thread is waiting for something to happen, the condition name is an indication of what the thread is waiting for, but there is no immediate way to tell which other threads cause the condition to happen.

The `cond_instances` table has these columns:

- `NAME`

The instrument name associated with the condition.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented condition.

`TRUNCATE TABLE` is not permitted for the `cond_instances` table.

### 25.12.3.2 The `file_instances` Table

The `file_instances` table lists all the files seen by the Performance Schema when executing file I/O instrumentation. If a file on disk has never been opened, it is not in `file_instances`. When a file is deleted from the disk, it is also removed from the `file_instances` table.

The `file_instances` table has these columns:

- `FILE_NAME`

The file name.

- `EVENT_NAME`

The instrument name associated with the file.

- `OPEN_COUNT`

The count of open handles on the file. If a file was opened and then closed, it was opened 1 time, but `OPEN_COUNT` is 0. To list all the files currently opened by the server, use `WHERE OPEN_COUNT > 0`.

`TRUNCATE TABLE` is not permitted for the `file_instances` table.

### 25.12.3.3 The `mutex_instances` Table

The `mutex_instances` table lists all the mutexes seen by the Performance Schema while the server executes. A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to some common resource. The resource is said to be “protected” by the mutex.

When two threads executing in the server (for example, two user sessions executing a query simultaneously) do need to access the same resource (a file, a buffer, or some piece of data), these two threads compete against each other, so that the first query to obtain a lock on the mutex causes the other query to wait until the first is done and unlocks the mutex.

The work performed while holding a mutex is said to be in a “critical section,” and multiple queries do execute this critical section in a serialized way (one at a time), which is a potential bottleneck.

The `mutex_instances` table has these columns:

- `NAME`

The instrument name associated with the mutex.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented mutex.

- `LOCKED_BY_THREAD_ID`

When a thread currently has a mutex locked, `LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

`TRUNCATE TABLE` is not permitted for the `mutex_instances` table.

For every mutex instrumented in the code, the Performance Schema provides the following information.

- The `setup_instruments` table lists the name of the instrumentation point, with the prefix `wait/` `synch/mutex/`.
- When some code creates a mutex, a row is added to the `mutex_instances` table. The `OBJECT_INSTANCE_BEGIN` column is a property that uniquely identifies the mutex.
- When a thread attempts to lock a mutex, the `events_waits_current` table shows a row for that thread, indicating that it is waiting on a mutex (in the `EVENT_NAME` column), and indicating which mutex is waited on (in the `OBJECT_INSTANCE_BEGIN` column).
- When a thread succeeds in locking a mutex:
  - `events_waits_current` shows that the wait on the mutex is completed (in the `TIMER_END` and `TIMER_WAIT` columns)
  - The completed wait event is added to the `events_waits_history` and `events_waits_history_long` tables
  - `mutex_instances` shows that the mutex is now owned by the thread (in the `THREAD_ID` column).
- When a thread unlocks a mutex, `mutex_instances` shows that the mutex now has no owner (the `THREAD_ID` column is `NULL`).
- When a mutex object is destroyed, the corresponding row is removed from `mutex_instances`.

By performing queries on both of the following tables, a monitoring application or a DBA can detect bottlenecks or deadlocks between threads that involve mutexes:

- `events_waits_current`, to see what mutex a thread is waiting for
- `mutex_instances`, to see which other thread currently owns a mutex

#### 25.12.3.4 The `rwlock_instances` Table

The `rwlock_instances` table lists all the `rwlock` (read write lock) instances seen by the Performance Schema while the server executes. An `rwlock` is a synchronization mechanism used in the code to enforce that threads at a given time can have access to some common resource following certain rules. The resource is said to be “protected” by the `rwlock`. The access is either shared (many threads can have a read lock at the same time), exclusive (only one thread can have a write lock at a given time), or shared-exclusive (a thread can have a write lock while permitting inconsistent reads by other threads). Shared-exclusive access is otherwise known as an `sxlock` and optimizes concurrency and improves scalability for read-write workloads.

Depending on how many threads are requesting a lock, and the nature of the locks requested, access can be either granted in shared mode, exclusive mode, shared-exclusive mode or not granted at all, waiting for other threads to finish first.

The `rwlock_instances` table has these columns:

- `NAME`  
The instrument name associated with the lock.
- `OBJECT_INSTANCE_BEGIN`  
The address in memory of the instrumented lock.
- `WRITE_LOCKED_BY_THREAD_ID`

When a thread currently has an `rwlock` locked in exclusive (write) mode, `WRITE_LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

- `READ_LOCKED_BY_COUNT`

When a thread currently has an `rwlock` locked in shared (read) mode, `READ_LOCKED_BY_COUNT` is incremented by 1. This is a counter only, so it cannot be used directly to find which thread holds a read lock, but it can be used to see whether there is a read contention on an `rwlock`, and see how many readers are currently active.

`TRUNCATE TABLE` is not permitted for the `rwlock_instances` table.

By performing queries on both of the following tables, a monitoring application or a DBA may detect some bottlenecks or deadlocks between threads that involve locks:

- `events_waits_current`, to see what `rwlock` a thread is waiting for
- `rwlock_instances`, to see which other thread currently owns an `rwlock`

There is a limitation: The `rwlock_instances` can be used only to identify the thread holding a write lock, but not the threads holding a read lock.

#### 25.12.3.5 The `socket_instances` Table

The `socket_instances` table provides a real-time snapshot of the active connections to the MySQL server. The table contains one row per TCP/IP or Unix socket file connection. Information available in this table provides a real-time snapshot of the active connections to the server. (Additional information is available in socket summary tables, including network activity such as socket operations and number of bytes transmitted and received; see [Section 25.12.15.8, “Socket Summary Tables”](#)).

```
mysql> SELECT * FROM performance_schema.socket_instances\G
***** 1. row *****
EVENT_NAME: wait/io/socket/sql/server_unix_socket
OBJECT_INSTANCE_BEGIN: 4316619408
 THREAD_ID: 1
 SOCKET_ID: 16
 IP:
 PORT: 0
 STATE: ACTIVE
***** 2. row *****
EVENT_NAME: wait/io/socket/sql/client_connection
OBJECT_INSTANCE_BEGIN: 4316644608
 THREAD_ID: 21
 SOCKET_ID: 39
 IP: 127.0.0.1
 PORT: 55233
 STATE: ACTIVE
***** 3. row *****
EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
OBJECT_INSTANCE_BEGIN: 4316699040
 THREAD_ID: 1
 SOCKET_ID: 14
 IP: 0.0.0.0
 PORT: 50603
 STATE: ACTIVE
```

Socket instruments have names of the form `wait/io/socket/sql/socket_type` and are used like this:

1. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcpip_socket` or `server_unix_socket`, respectively.
2. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.

3. When a connection terminates, the row in `socket_instances` corresponding to it is deleted.

The `socket_instances` table has these columns:

- `EVENT_NAME`

The name of the `wait/io/socket/*` instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

- `OBJECT_INSTANCE_BEGIN`

This column uniquely identifies the socket. The value is the address of an object in memory.

- `THREAD_ID`

The internal thread identifier assigned by the server. Each socket is managed by a single thread, so each socket can be mapped to a thread which can be mapped to a server process.

- `SOCKET_ID`

The internal file handle assigned to the socket.

- `IP`

The client IP address. The value may be either an IPv4 or IPv6 address, or blank to indicate a Unix socket file connection.

- `PORT`

The TCP/IP port number, in the range from 0 to 65535.

- `STATE`

The socket status, either `IDLE` or `ACTIVE`. Wait times for active sockets are tracked using the corresponding socket instrument. Wait times for idle sockets are tracked using the `idle` instrument.

A socket is idle if it is waiting for a request from the client. When a socket becomes idle, the event row in `socket_instances` that is tracking the socket switches from a status of `ACTIVE` to `IDLE`. The `EVENT_NAME` value remains `wait/io/socket/*`, but timing for the instrument is suspended. Instead, an event is generated in the `events_waits_current` table with an `EVENT_NAME` value of `idle`.

When the next request is received, the `idle` event terminates, the socket instance switches from `IDLE` to `ACTIVE`, and timing of the socket instrument resumes.

`TRUNCATE TABLE` is not permitted for the `socket_instances` table.

The `IP:PORT` column combination value identifies the connection. This combination value is used in the `OBJECT_NAME` column of the `events_waits_xxx` tables, to identify the connection from which socket events come:

- For the Unix domain listener socket (`server_unix_socket`), the port is 0, and the IP is ‘’.
- For client connections via the Unix domain listener (`client_connection`), the port is 0, and the IP is ‘’.
- For the TCP/IP server listener socket (`server_tcpip_socket`), the port is always the master port (for example, 3306), and the IP is always `0.0.0.0`.
- For client connections via the TCP/IP listener (`client_connection`), the port is whatever the server assigns, but never 0. The IP is the IP of the originating host (`127.0.0.1` or `::1` for the local host)

## 25.12.4 Performance Schema Wait Event Tables

The Performance Schema instruments waits, which are events that take time. Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store wait events:

- `events_waits_current`: The current wait event for each thread.
- `events_waits_history`: The most recent wait events that have ended per thread.
- `events_waits_history_long`: The most recent wait events that have ended globally (across all threads).

The following sections describe the wait event tables. There are also summary tables that aggregate information about wait events; see [Section 25.12.15.1, “Wait Event Summary Tables”](#).

For more information about the relationship between the three wait event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

## Configuring Wait Event Collection

To control whether to collect wait events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains instruments with names that begin with `wait`. Use these instruments to enable or disable collection of individual wait event classes.
- The `setup_consumers` table contains consumer values with names corresponding to the current and historical wait event table names. Use these consumers to filter collection of wait events.

Some wait instruments are enabled by default; others are disabled. For example:

```
mysql> SELECT * FROM performance_schema.setup_instruments
 WHERE NAME LIKE 'wait/io/file/innodb%';
+-----+-----+-----+
| NAME | ENABLED | TIMED |
+-----+-----+-----+
| wait/io/file/innodb/innodb_data_file | YES | YES |
| wait/io/file/innodb/innodb_log_file | YES | YES |
| wait/io/file/innodb/innodb_temp_file | YES | YES |
+-----+-----+-----+
mysql> SELECT *
 FROM performance_schema.setup_instruments WHERE
 NAME LIKE 'wait/io/socket/%';
+-----+-----+-----+
| NAME | ENABLED | TIMED |
+-----+-----+-----+
| wait/io/socket/sql/server_tcpip_socket | NO | NO |
| wait/io/socket/sql/server_unix_socket | NO | NO |
| wait/io/socket/sql/client_connection | NO | NO |
+-----+-----+-----+
```

The wait consumers are disabled by default:

```
mysql> SELECT *
 FROM performance_schema.setup_consumers
 WHERE NAME LIKE 'events_waits%';
+-----+-----+
| NAME | ENABLED |
+-----+-----+
| events_waits_current | NO |
| events_waits_history | NO |
| events_waits_history_long | NO |
+-----+-----+
```

To control wait event collection at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='wait/%=ON'
performance-schema-consumer-events-waits-current=ON
performance-schema-consumer-events-waits-history=ON
performance-schema-consumer-events-waits-history-long=ON
```

- Disable:

```
[mysqld]
performance-schema-instrument='wait/%=OFF'
performance-schema-consumer-events-waits-current=OFF
performance-schema-consumer-events-waits-history=OFF
performance-schema-consumer-events-waits-history-long=OFF
```

To control wait event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- Enable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME LIKE 'wait/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE 'events_waits%';
```

- Disable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME LIKE 'wait/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE 'events_waits%';
```

To collect only specific wait events, enable only the corresponding wait instruments. To collect wait events only for specific wait event tables, enable the wait instruments but only the wait consumers corresponding to the desired tables.

The `setup_timers` table contains a row with a `NAME` value of `wait` that indicates the unit for wait event timing. The default unit is `CYCLE`:

```
mysql> SELECT *
 FROM performance_schema.setup_timers
 WHERE NAME = 'wait';
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| wait | CYCLE |
+-----+-----+
```

To change the timing unit, modify the `TIMER_NAME` value:

```
UPDATE performance_schema.setup_timers
SET TIMER_NAME = 'NANOSECOND'
WHERE NAME = 'wait';
```

For additional information about configuring event collection, see [Section 25.3, “Performance Schema Startup Configuration”](#), and [Section 25.4, “Performance Schema Runtime Configuration”](#).

## 25.12.4.1 The `events_waits_current` Table

The `events_waits_current` table contains current wait events. The table stores one row per thread showing the current status of the thread's most recent monitored wait event, so there is no system variable for configuring the table size.

Of the tables that contain wait event rows, `events_waits_current` is the most fundamental. Other tables that contain wait event rows are logically derived from the current events. For example, the `events_waits_history` and `events_waits_history_long` tables are collections of the most recent wait events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three wait event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect wait events, see [Section 25.12.4, “Performance Schema Wait Event Tables”](#).

The `events_waits_current` table has these columns:

- `THREAD_ID, EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved. For example, if a mutex or lock is being blocked, you can check the context in which this occurs.

- `TIMER_START, TIMER_END, TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillions of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 25.4.1, “Performance Schema Event Timing”](#).

- `SPINS`

For a mutex, the number of spin rounds. If the value is `NULL`, the code does not use spin rounds or spinning is not instrumented.

- `OBJECT_SCHEMA, OBJECT_NAME, OBJECT_TYPE, OBJECT_INSTANCE_BEGIN`

These columns identify the object “being acted on.” What that means depends on the object type.

For a synchronization object (`cond`, `mutex`, `rwlock`):

- `OBJECT_SCHEMA`, `OBJECT_NAME`, and `OBJECT_TYPE` are `NULL`.
- `OBJECT_INSTANCE_BEGIN` is the address of the synchronization object in memory.

For a file I/O object:

- `OBJECT_SCHEMA` is `NULL`.
- `OBJECT_NAME` is the file name.
- `OBJECT_TYPE` is `FILE`.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

For a socket object:

- `OBJECT_NAME` is the `IP:PORT` value for the socket.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

For a table I/O object:

- `OBJECT_SCHEMA` is the name of the schema that contains the table.
- `OBJECT_NAME` is the table name.
- `OBJECT_TYPE` is `TABLE` for a persistent base table or `TEMPORARY_TABLE` for a temporary table.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

An `OBJECT_INSTANCE_BEGIN` value itself has no meaning, except that different values indicate different objects. `OBJECT_INSTANCE_BEGIN` can be used for debugging. For example, it can be used with `GROUP BY OBJECT_INSTANCE_BEGIN` to see whether the load on 1,000 mutexes (that protect, say, 1,000 pages or blocks of data) is spread evenly or just hitting a few bottlenecks. This can help you correlate with other sources of information if you see the same object address in a log file or another debugging or performance tool.

- `INDEX_NAME`

The name of the index used. `PRIMARY` indicates the table primary index. `NULL` means that no index was used.

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`.

- `OPERATION`

The type of operation performed, such as `lock`, `read`, or `write`.

- `NUMBER_OF_BYTES`

The number of bytes read or written by the operation. For table I/O waits (events for the `wait/io/table/sql/handler` instrument), `NUMBER_OF_BYTES` indicates the number of rows. If the

value is greater than 1, the event is for a batch I/O operation. The following discussion describes the difference between exclusively single-row reporting and reporting that reflects batch I/O.

MySQL executes joins using a nested-loop implementation. The job of the Performance Schema instrumentation is to provide row count and accumulated execution time per table in the join. Assume a join query of the following form that is executed using a table join order of `t1, t2, t3`:

```
SELECT ... FROM t1 JOIN t2 ON ... JOIN t3 ON ...
```

Table “fanout” is the increase or decrease in number of rows from adding a table during join processing. If the fanout for table `t3` is greater than 1, the majority of row-fetch operations are for that table. Suppose that the join accesses 10 rows from `t1`, 20 rows from `t2` per row from `t1`, and 30 rows from `t3` per row of table `t2`. With single-row reporting, the total number of instrumented operations is:

$$10 + (10 * 20) + (10 * 20 * 30) = 6210$$

A significant reduction in the number of instrumented operations is achievable by aggregating them per scan (that is, per unique combination of rows from `t1` and `t2`). With batch I/O reporting, the Performance Schema produces an event for each scan of the innermost table `t3` rather than for each row, and the number of instrumented row operations reduces to:

$$10 + (10 * 20) + (10 * 20) = 410$$

That is a reduction of 93%, illustrating how the batch-reporting strategy significantly reduces Performance Schema overhead for table I/O by reducing the number of reporting calls. The tradeoff is lesser accuracy for event timing. Rather than time for an individual row operation as in per-row reporting, timing for batch I/O includes time spent for operations such as join buffering, aggregation, and returning rows to the client.

For batch I/O reporting to occur, these conditions must be true:

- Query execution accesses the innermost table of a query block (for a single-table query, that table counts as innermost)
- Query execution does not request a single row from the table (so, for example, `eq_ref` access prevents use of batch reporting)
- Query execution does not evaluate a subquery containing table access for the table
- `FLAGS`

Reserved for future use.

`TRUNCATE TABLE` is permitted for the `events_waits_current` table. It removes the rows.

#### 25.12.4.2 The `events_waits_history` Table

The `events_waits_history` table contains the `N` most recent wait events that have ended per thread. Wait events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of `N` during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_waits_history_size` system variable at server startup.

The `events_waits_history` table has the same columns as `events_waits_current`. See Section 25.12.4.1, “The `events_waits_current` Table”.

`TRUNCATE TABLE` is permitted for the `events_waits_history` table. It removes the rows.

For more information about the relationship between the three wait event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect wait events, see [Section 25.12.4, “Performance Schema Wait Event Tables”](#).

### 25.12.4.3 The `events_waits_history_long` Table

The `events_waits_history_long` table contains  $N$  the most recent wait events that have ended globally, across all threads. Wait events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The Performance Schema autosizes the value of  $N$  during server startup. To set the table size explicitly, set the `performance_schema_events_waits_history_long_size` system variable at server startup.

The `events_waits_history_long` table has the same columns as `events_waits_current`. See [Section 25.12.4.1, “The `events\_waits\_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_waits_history_long` table. It removes the rows.

For more information about the relationship between the three wait event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect wait events, see [Section 25.12.4, “Performance Schema Wait Event Tables”](#).

## 25.12.5 Performance Schema Stage Event Tables

The Performance Schema instruments stages, which are steps during the statement-execution process, such as parsing a statement, opening a table, or performing a `filesort` operation.

Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table. Stages begin and end when state values change.

Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store stage events:

- `events_stages_current`: The current stage event for each thread.
- `events_stages_history`: The most recent stage events that have ended per thread.
- `events_stages_history_long`: The most recent stage events that have ended globally (across all threads).

The following sections describe the stage event tables. There are also summary tables that aggregate information about stage events; see [Section 25.12.15.2, “Stage Summary Tables”](#).

For more information about the relationship between the three stage event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

- [Configuring Stage Event Collection](#)
- [Stage Event Progress Information](#)

### Configuring Stage Event Collection

To control whether to collect stage events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains instruments with names that begin with `stage`. Use these instruments to enable or disable collection of individual stage event classes.
- The `setup_consumers` table contains consumer values with names corresponding to the current and historical stage event table names. Use these consumers to filter collection of stage events.

Other than those instruments that provide statement progress information, the stage instruments are disabled by default. For example:

```
mysql> SELECT *
 FROM performance_schema.setup_instruments
 WHERE NAME RLIKE 'stage/sql/[a-c]';
+-----+-----+-----+
| NAME | ENABLED | TIMED |
+-----+-----+-----+
| stage/sql/After create | NO | NO |
| stage/sql/allocating local table | NO | NO |
| stage/sql/altering table | NO | NO |
| stage/sql/committing alter table to storage engine | NO | NO |
| stage/sql/Changing master | NO | NO |
| stage/sql/Checking master version | NO | NO |
| stage/sql/checking permissions | NO | NO |
| stage/sql/checking privileges on cached query | NO | NO |
| stage/sql/checking query cache for query | NO | NO |
| stage/sql/cleaning up | NO | NO |
| stage/sql/closing tables | NO | NO |
| stage/sql/Connecting to master | NO | NO |
| stage/sql/converting HEAP to MyISAM | NO | NO |
| stage/sql/Copying to group table | NO | NO |
| stage/sql/Copying to tmp table | NO | NO |
| stage/sql/copy to tmp table | NO | NO |
| stage/sql/Creating sort index | NO | NO |
| stage/sql/creating table | NO | NO |
| stage/sql/Creating tmp table | NO | NO |
+-----+-----+-----+
```

Stage event instruments that provide statement progress information are enabled and timed by default:

```
mysql> SELECT *
 FROM performance_schema.setup_instruments
 WHERE ENABLED='YES' AND NAME LIKE "stage/%";
+-----+-----+-----+
| NAME | ENABLED | TIMED |
+-----+-----+-----+
| stage/sql/copy to tmp table | YES | YES |
| stage/innodb/alter table (end) | YES | YES |
| stage/innodb/alter table (flush) | YES | YES |
| stage/innodb/alter table (insert) | YES | YES |
| stage/innodb/alter table (log apply index) | YES | YES |
| stage/innodb/alter table (log apply table) | YES | YES |
| stage/innodb/alter table (merge sort) | YES | YES |
| stage/innodb/alter table (read PK and internal sort) | YES | YES |
| stage/innodb/buffer pool load | YES | YES |
+-----+-----+-----+
```

The stage consumers are disabled by default:

```
mysql> SELECT *
 FROM performance_schema.setup_consumers
 WHERE NAME LIKE 'events_stages%';
+-----+-----+
| NAME | ENABLED |
+-----+-----+
| events_stages_current | NO |
| events_stages_history | NO |
| events_stages_history_long | NO |
+-----+-----+
```

To control stage event collection at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='stage/%=ON'
performance-schema-consumer-events-stages-current=ON
performance-schema-consumer-events-stages-history=ON
performance-schema-consumer-events-stages-history-long=ON
```

- Disable:

```
[mysqld]
performance-schema-instrument='stage/%=OFF'
performance-schema-consumer-events-stages-current=OFF
performance-schema-consumer-events-stages-history=OFF
performance-schema-consumer-events-stages-history-long=OFF
```

To control stage event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- Enable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME LIKE 'stage/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE 'events_stages%';
```

- Disable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME LIKE 'stage/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE 'events_stages%';
```

To collect only specific stage events, enable only the corresponding stage instruments. To collect stage events only for specific stage event tables, enable the stage instruments but only the stage consumers corresponding to the desired tables.

The `setup_timers` table contains a row with a `NAME` value of `stage` that indicates the unit for stage event timing. The default unit is `NANOSECOND`:

```
mysql> SELECT *
 FROM performance_schema.setup_timers
 WHERE NAME = 'stage';
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| stage | NANOSECOND |
+-----+-----+
```

To change the timing unit, modify the `TIMER_NAME` value:

```
UPDATE performance_schema.setup_timers
SET TIMER_NAME = 'MICROSECOND'
WHERE NAME = 'stage';
```

For additional information about configuring event collection, see [Section 25.3, “Performance Schema Startup Configuration”](#), and [Section 25.4, “Performance Schema Runtime Configuration”](#).

## Stage Event Progress Information

The Performance Schema stage event tables contain two columns that, taken together, provide a stage progress indicator for each row:

- `WORK_COMPLETED`: The number of work units completed for the stage
- `WORK_ESTIMATED`: The number of work units expected for the stage

Each column is `NULL` if no progress information is provided for an instrument. Interpretation of the information, if it is available, depends entirely on the instrument implementation. The Performance Schema tables provide a container to store progress data, but make no assumptions about the semantics of the metric itself:

- A “work unit” is an integer metric that increases over time during execution, such as the number of bytes, rows, files, or tables processed. The definition of “work unit” for a particular instrument is left to the instrumentation code providing the data.
- The `WORK_COMPLETED` value can increase one or many units at a time, depending on the instrumented code.
- The `WORK_ESTIMATED` value can change during the stage, depending on the instrumented code.

Instrumentation for a stage event progress indicator can implement any of the following behaviors:

- No progress instrumentation

This is the most typical case, where no progress data is provided. The `WORK_COMPLETED` and `WORK_ESTIMATED` columns are both `NULL`.

- Unbounded progress instrumentation

Only the `WORK_COMPLETED` column is meaningful. No data is provided for the `WORK_ESTIMATED` column, which displays 0.

By querying the `events_stages_current` table for the monitored session, a monitoring application can report how much work has been performed so far, but cannot report whether the stage is near completion. Currently, no stages are instrumented like this.

- Bounded progress instrumentation

The `WORK_COMPLETED` and `WORK_ESTIMATED` columns are both meaningful.

This type of progress indicator is appropriate for an operation with a defined completion criterion, such as the table-copy instrument described later. By querying the `events_stages_current` table for the monitored session, a monitoring application can report how much work has been performed so far, and can report the overall completion percentage for the stage, by computing the `WORK_COMPLETED / WORK_ESTIMATED` ratio.

The `stage/sql/copy to tmp table` instrument illustrates how progress indicators work. During execution of an `ALTER TABLE` statement, the `stage/sql/copy to tmp table` stage is used, and this stage can execute potentially for a long time, depending on the size of the data to copy.

The table-copy task has a defined termination (all rows copied), and the `stage/sql/copy to tmp table` stage is instrumented to provide bounded progress information: The work unit used is number of rows copied, `WORK_COMPLETED` and `WORK_ESTIMATED` are both meaningful, and their ratio indicates task percentage complete.

To enable the instrument and the relevant consumers, execute these statements:

```
UPDATE performance_schema.setup_instruments
SET ENABLED='YES'
WHERE NAME='stage/sql/copy to tmp table';

UPDATE performance_schema.setup_consumers
SET ENABLED='YES'
WHERE NAME LIKE 'events_stages_%';
```

To see the progress of an ongoing `ALTER TABLE` statement, select from the `events_stages_current` table.

### 25.12.5.1 The `events_stages_current` Table

The `events_stages_current` table contains current stage events. The table stores one row per thread showing the current status of the thread's most recent monitored stage event, so there is no system variable for configuring the table size.

Of the tables that contain stage event rows, `events_stages_current` is the most fundamental. Other tables that contain stage event rows are logically derived from the current events. For example, the `events_stages_history` and `events_stages_history_long` tables are collections of the most recent stage events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three stage event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect stage events, see [Section 25.12.5, “Performance Schema Stage Event Tables”](#).

The `events_stages_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 25.4.1, “Performance Schema Event Timing”](#).

- `WORK_COMPLETED`, `WORK_ESTIMATED`

These columns provide stage progress information, for instruments that have been implemented to produce such information. `WORK_COMPLETED` indicates how many work units have been completed for the stage, and `WORK_ESTIMATED` indicates how many work units are expected for the stage. For more information, see [Stage Event Progress Information](#).

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested. The nesting event for a stage event is usually a statement event.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`.

`TRUNCATE TABLE` is permitted for the `events_stages_current` table. It removes the rows.

### 25.12.5.2 The `events_stages_history` Table

The `events_stages_history` table contains the `N` most recent stage events that have ended per thread. Stage events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of `N` during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_stages_history_size` system variable at server startup.

The `events_stages_history` table has the same columns as `events_stages_current`. See [Section 25.12.5.1, “The `events\_stages\_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_stages_history` table. It removes the rows.

For more information about the relationship between the three stage event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect stage events, see [Section 25.12.5, “Performance Schema Stage Event Tables”](#).

### 25.12.5.3 The `events_stages_history_long` Table

The `events_stages_history_long` table contains the `N` most recent stage events that have ended globally, across all threads. Stage events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The Performance Schema autosizes the value of `N` during server startup. To set the table size explicitly, set the `performance_schema_events_stages_history_long_size` system variable at server startup.

The `events_stages_history_long` table has the same columns as `events_stages_current`. See [Section 25.12.5.1, “The `events\_stages\_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_stages_history_long` table. It removes the rows.

For more information about the relationship between the three stage event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect stage events, see [Section 25.12.5, “Performance Schema Stage Event Tables”](#).

## 25.12.6 Performance Schema Statement Event Tables

The Performance Schema instruments statement execution. Statement events occur at a high level of the event hierarchy. Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store statement events:

- `events_statements_current`: The current statement event for each thread.
- `events_statements_history`: The most recent statement events that have ended per thread.
- `events_statements_history_long`: The most recent statement events that have ended globally (across all threads).
- `prepared_statements_instances`: Prepared statement instances and statistics

The following sections describe the statement event tables. There are also summary tables that aggregate information about statement events; see [Section 25.12.15.3, “Statement Summary Tables”](#).

For more information about the relationship between the three `events_statements_xxx` event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

- [Configuring Statement Event Collection](#)
- [Statement Monitoring](#)

### Configuring Statement Event Collection

To control whether to collect statement events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains instruments with names that begin with `statement`. Use these instruments to enable or disable collection of individual statement event classes.
- The `setup_consumers` table contains consumer values with names corresponding to the current and historical statement event table names, and the statement digest consumer. Use these consumers to filter collection of statement events and statement digesting.

The statement instruments are enabled by default, and the `events_statements_current`, `events_statements_history`, and `statements_digest` statement consumers are enabled by default:

```
mysql> SELECT *
 FROM performance_schema.setup_instruments
 WHERE NAME LIKE 'statement%';
+-----+-----+-----+
| NAME | ENABLED | TIMED |
+-----+-----+-----+
| statement/sql/select | YES | YES |
| statement/sql/create_table | YES | YES |
| statement/sql/create_index | YES | YES |
...
| statement/sp/stmt | YES | YES |
| statement/sp/set | YES | YES |
| statement/sp/set_trigger_field | YES | YES |
| statement/scheduler/event | YES | YES |
| statement/com/Sleep | YES | YES |
| statement/com/Quit | YES | YES |
| statement/com/Init DB | YES | YES |
...
| statement/abstract/Query | YES | YES |
| statement/abstract/new_packet | YES | YES |
| statement/abstract/relay_log | YES | YES |
```

```
+-----+-----+-----+
mysql> SELECT *
 FROM performance_schema.setup_consumers
 WHERE NAME LIKE '%statements%';
+-----+-----+
| NAME | ENABLED |
+-----+-----+
| events_statements_current | YES |
| events_statements_history | YES |
| events_statements_history_long | NO |
| statements_digest | YES |
+-----+-----+
```

To control statement event collection at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='statement/%=ON'
performance-schema-consumer-events-statements-current=ON
performance-schema-consumer-events-statements-history=ON
performance-schema-consumer-events-statements-history-long=ON
performance-schema-consumer-statements-digest=ON
```

- Disable:

```
[mysqld]
performance-schema-instrument='statement/%=OFF'
performance-schema-consumer-events-statements-current=OFF
performance-schema-consumer-events-statements-history=OFF
performance-schema-consumer-events-statements-history-long=OFF
performance-schema-consumer-statements-digest=OFF
```

To control statement event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- Enable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME LIKE 'statement/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE '%statements%';
```

- Disable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME LIKE 'statement/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE '%statements%';
```

To collect only specific statement events, enable only the corresponding statement instruments. To collect statement events only for specific statement event tables, enable the statement instruments but only the statement consumers corresponding to the desired tables.

The `setup_timers` table contains a row with a `NAME` value of `statement` that indicates the unit for statement event timing. The default unit is `NANOSECOND`:

```
mysql> SELECT *
 FROM performance_schema.setup_timers
 WHERE NAME = 'statement';
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
```

| statement | NANOSECOND |
|-----------|------------|

To change the timing unit, modify the `TIMER_NAME` value:

```
UPDATE performance_schema.setup_timers
SET TIMER_NAME = 'MICROSECOND'
WHERE NAME = 'statement';
```

For additional information about configuring event collection, see [Section 25.3, “Performance Schema Startup Configuration”](#), and [Section 25.4, “Performance Schema Runtime Configuration”](#).

## Statement Monitoring

Statement monitoring begins from the moment the server sees that activity is requested on a thread, to the moment when all activity has ceased. Typically, this means from the time the server gets the first packet from the client to the time the server has finished sending the response. Statements within stored programs are monitored like other statements.

When the Performance Schema instruments a request (server command or SQL statement), it uses instrument names that proceed in stages from more general (or “abstract”) to more specific until it arrives at a final instrument name.

Final instrument names correspond to server commands and SQL statements:

- Server commands correspond to the `COM_xxx` codes defined in the `mysql_com.h` header file and processed in `sql/sql_parse.cc`. Examples are `COM_PING` and `COM_QUIT`. Instruments for commands have names that begin with `statement/com`, such as `statement/com/Ping` and `statement/com/Quit`.
- SQL statements are expressed as text, such as `DELETE FROM t1` or `SELECT * FROM t2`. Instruments for SQL statements have names that begin with `statement/sql`, such as `statement/sql/delete` and `statement/sql/select`.

Some final instrument names are specific to error handling:

- `statement/com/Error` accounts for messages received by the server that are out of band. It can be used to detect commands sent by clients that the server does not understand. This may be helpful for purposes such as identifying clients that are misconfigured or using a version of MySQL more recent than that of the server, or clients that are attempting to attack the server.
- `statement/sql/error` accounts for SQL statements that fail to parse. It can be used to detect malformed queries sent by clients. A query that fails to parse differs from a query that parses but fails due to an error during execution. For example, `SELECT * FROM` is malformed, and the `statement/sql/error` instrument is used. By contrast, `SELECT *` parses but fails with a `No tables used` error. In this case, `statement/sql/select` is used and the statement event contains information to indicate the nature of the error.

A request can be obtained from any of these sources:

- As a command or statement request from a client, which sends the request as packets
- As a statement string read from the relay log on a replica
- As an event from the Event Scheduler

The details for a request are not initially known and the Performance Schema proceeds from abstract to specific instrument names in a sequence that depends on the source of the request.

For a request received from a client:

1. When the server detects a new packet at the socket level, a new statement is started with an abstract instrument name of `statement/abstract/new_packet`.
2. When the server reads the packet number, it knows more about the type of request received, and the Performance Schema refines the instrument name. For example, if the request is a `COM_PING` packet, the instrument name becomes `statement/com/Ping` and that is the final name. If the request is a `COM_QUERY` packet, it is known to correspond to an SQL statement but not the particular type of statement. In this case, the instrument changes from one abstract name to a more specific but still abstract name, `statement/abstract/Query`, and the request requires further classification.
3. If the request is a statement, the statement text is read and given to the parser. After parsing, the exact statement type is known. If the request is, for example, an `INSERT` statement, the Performance Schema refines the instrument name from `statement/abstract/Query` to `statement/sql/insert`, which is the final name.

For a request read as a statement from the relay log on a replica:

1. Statements in the relay log are stored as text and are read as such. There is no network protocol, so the `statement/abstract/new_packet` instrument is not used. Instead, the initial instrument is `statement/abstract/relay_log`.
2. When the statement is parsed, the exact statement type is known. If the request is, for example, an `INSERT` statement, the Performance Schema refines the instrument name from `statement/abstract/Query` to `statement/sql/insert`, which is the final name.

The preceding description applies only for statement-based replication. For row-based replication, table I/O done on the replica as it processes row changes can be instrumented, but row events in the relay log do not appear as discrete statements.

For a request received from the Event Scheduler:

The event execution is instrumented using the name `statement/scheduler/event`. This is the final name.

Statements executed within the event body are instrumented using `statement/sql/*` names, without use of any preceding abstract instrument. An event is a stored program, and stored programs are precompiled in memory before execution. Consequently, there is no parsing at runtime and the type of each statement is known by the time it executes.

Statements executed within the event body are child statements. For example, if an event executes an `INSERT` statement, execution of the event itself is the parent, instrumented using `statement/scheduler/event`, and the `INSERT` is the child, instrumented using `statement/sql/insert`. The parent/child relationship holds *between* separate instrumented operations. This differs from the sequence of refinement that occurs *within* a single instrumented operation, from abstract to final instrument names.

For statistics to be collected for statements, it is not sufficient to enable only the final `statement/sql/*` instruments used for individual statement types. The abstract `statement/abstract/*` instruments must be enabled as well. This should not normally be an issue because all statement instruments are enabled by default. However, an application that enables or disables statement instruments selectively must take into account that disabling abstract instruments also disables statistics collection for the individual statement instruments. For example, to collect statistics for `INSERT` statements, `statement/sql/insert` must be enabled, but also `statement/abstract/new_packet` and `statement/abstract/Query`. Similarly, for replicated statements to be instrumented, `statement/abstract/relay_log` must be enabled.

No statistics are aggregated for abstract instruments such as `statement/abstract/Query` because no statement is ever classified with an abstract instrument as the final statement name.

### 25.12.6.1 The `events_statements_current` Table

The `events_statements_current` table contains current statement events. The table stores one row per thread showing the current status of the thread's most recent monitored statement event, so there is no system variable for configuring the table size.

Of the tables that contain statement event rows, `events_statements_current` is the most fundamental. Other tables that contain statement event rows are logically derived from the current events. For example, the `events_statements_history` and `events_statements_history_long` tables are collections of the most recent statement events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three `events_statements_xxx` event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect statement events, see [Section 25.12.6, “Performance Schema Statement Event Tables”](#).

The `events_statements_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument from which the event was collected. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

For SQL statements, the `EVENT_NAME` value initially is `statement/com/Query` until the statement is parsed, then changes to a more appropriate value, as described in [Section 25.12.6, “Performance Schema Statement Event Tables”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 25.4.1, “Performance Schema Event Timing”](#).

- [LOCK\\_TIME](#)

The time spent waiting for table locks. This value is computed in microseconds but normalized to picoseconds for easier comparison with other Performance Schema timers.

- [SQL\\_TEXT](#)

The text of the SQL statement. For a command not associated with an SQL statement, the value is [NULL](#).

The maximum space available for statement display is 1024 bytes by default. To change this value, set the [performance\\_schema\\_max\\_sql\\_text\\_length](#) system variable at server startup.

- [DIGEST](#)

The statement digest MD5 value as a string of 32 hexadecimal characters, or [NULL](#) if the [statements\\_digest](#) consumer is [no](#). For more information about statement digesting, see [Section 25.10, “Performance Schema Statement Digests”](#).

- [DIGEST\\_TEXT](#)

The normalized statement digest text, or [NULL](#) if the [statements\\_digest](#) consumer is [no](#). For more information about statement digesting, see [Section 25.10, “Performance Schema Statement Digests”](#).

The [performance\\_schema\\_max\\_digest\\_length](#) system variable determines the maximum number of bytes available per session for digest value storage. However, the display length of statement digests may be longer than the available buffer size due to encoding of statement elements such as keywords and literal values in digest buffer. Consequently, values selected from the [DIGEST\\_TEXT](#) column of statement event tables may appear to exceed the [performance\\_schema\\_max\\_digest\\_length](#) value.

- [CURRENT\\_SCHEMA](#)

The default database for the statement, [NULL](#) if there is none.

- [OBJECT\\_SCHEMA](#), [OBJECT\\_NAME](#), [OBJECT\\_TYPE](#)

For nested statements (stored programs), these columns contain information about the parent statement. Otherwise they are [NULL](#).

- [OBJECT\\_INSTANCE\\_BEGIN](#)

This column identifies the statement. The value is the address of an object in memory.

- [MYSQL\\_ERRNO](#)

The statement error number, from the statement diagnostics area.

- [RETURNED\\_SQLSTATE](#)

The statement SQLSTATE value, from the statement diagnostics area.

- [MESSAGE\\_TEXT](#)

The statement error message, from the statement diagnostics area.

- [ERRORS](#)

Whether an error occurred for the statement. The value is 0 if the SQLSTATE value begins with [00](#) (completion) or [01](#) (warning). The value is 1 if the SQLSTATE value is anything else.

- [WARNINGS](#)

The number of warnings, from the statement diagnostics area.

- [ROWS\\_AFFECTED](#)

The number of rows affected by the statement. For a description of the meaning of “affected,” see [mysql\\_affected\\_rows\(\)](#).

- [ROWS\\_SENT](#)

The number of rows returned by the statement.

- [ROWS\\_EXAMINED](#)

The number of rows examined by the server layer (not counting any processing internal to storage engines).

- [CREATED\\_TMP\\_DISK\\_TABLES](#)

Like the [Created\\_tmp\\_disk\\_tables](#) status variable, but specific to the statement.

- [CREATED\\_TMP\\_TABLES](#)

Like the [Created\\_tmp\\_tables](#) status variable, but specific to the statement.

- [SELECT\\_FULL\\_JOIN](#)

Like the [Select\\_full\\_join](#) status variable, but specific to the statement.

- [SELECT\\_FULL\\_RANGE\\_JOIN](#)

Like the [Select\\_full\\_range\\_join](#) status variable, but specific to the statement.

- [SELECT\\_RANGE](#)

Like the [Select\\_range](#) status variable, but specific to the statement.

- [SELECT\\_RANGE\\_CHECK](#)

Like the [Select\\_range\\_check](#) status variable, but specific to the statement.

- [SELECT\\_SCAN](#)

Like the [Select\\_scan](#) status variable, but specific to the statement.

- [SORT\\_MERGE\\_PASSES](#)

Like the [Sort\\_merge\\_passes](#) status variable, but specific to the statement.

- [SORT\\_RANGE](#)

Like the [Sort\\_range](#) status variable, but specific to the statement.

- [SORT\\_ROWS](#)

Like the [Sort\\_rows](#) status variable, but specific to the statement.

- [SORT\\_SCAN](#)

Like the [Sort\\_scan](#) status variable, but specific to the statement.

- [NO\\_INDEX\\_USED](#)

1 if the statement performed a table scan without using an index, 0 otherwise.

- `NO_GOOD_INDEX_USED`

1 if the server found no good index to use for the statement, 0 otherwise. For additional information, see the description of the `Extra` column from `EXPLAIN` output for the `Range checked for each record` value in [Section 8.8.2, “EXPLAIN Output Format”](#).

- `NESTING_EVENT_ID`, `NESTING_EVENT_TYPE`, `NESTING_EVENT_LEVEL`

These three columns are used with other columns to provide information as follows for top-level (unnested) statements and nested statements (executed within a stored program).

For top level statements:

```
OBJECT_TYPE = NULL
OBJECT_SCHEMA = NULL
OBJECT_NAME = NULL
NESTING_EVENT_ID = NULL
NESTING_EVENT_TYPE = NULL
NESTING_LEVEL = 0
```

For nested statements:

```
OBJECT_TYPE = the parent statement object type
OBJECT_SCHEMA = the parent statement object schema
OBJECT_NAME = the parent statement object name
NESTING_EVENT_ID = the parent statement EVENT_ID
NESTING_EVENT_TYPE = 'STATEMENT'
NESTING_LEVEL = the parent statement NESTING_LEVEL plus one
```

`TRUNCATE TABLE` is permitted for the `events_statements_current` table. It removes the rows.

### 25.12.6.2 The `events_statements_history` Table

The `events_statements_history` table contains the `N` most recent statement events that have ended per thread. Statement events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of `N` during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_statements_history_size` system variable at server startup.

The `events_statements_history` table has the same columns as `events_statements_current`. See [Section 25.12.6.1, “The `events\_statements\_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_statements_history` table. It removes the rows.

For more information about the relationship between the three `events_statements_xxx` event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect statement events, see [Section 25.12.6, “Performance Schema Statement Event Tables”](#).

### 25.12.6.3 The `events_statements_history_long` Table

The `events_statements_history_long` table contains the `N` most recent statement events that have ended globally, across all threads. Statement events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The value of `N` is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_statements_history_long_size` system variable at server startup.

The `events_statements_history_long` table has the same columns as `events_statements_current`. See [Section 25.12.6.1, “The events\\_statements\\_current Table”](#).

`TRUNCATE TABLE` is permitted for the `events_statements_history_long` table. It removes the rows.

For more information about the relationship between the three `events_statements_xxx` event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect statement events, see [Section 25.12.6, “Performance Schema Statement Event Tables”](#).

## 25.12.6.4 The prepared\_statements\_instances Table

The Performance Schema provides instrumentation for prepared statements, for which there are two protocols:

- The binary protocol. This is accessed through the MySQL C API and maps onto underlying server commands as shown in the following table.

| C API Function                    | Corresponding Server Command  |
|-----------------------------------|-------------------------------|
| <code>mysql_stmt_prepare()</code> | <code>COM_STMT_PREPARE</code> |
| <code>mysql_stmt_execute()</code> | <code>COM_STMT_EXECUTE</code> |
| <code>mysql_stmt_close()</code>   | <code>COM_STMT_CLOSE</code>   |

- The text protocol. This is accessed using SQL statements and maps onto underlying server commands as shown in the following table.

| SQL Statement                                 | Corresponding Server Command           |
|-----------------------------------------------|----------------------------------------|
| <code>PREPARE</code>                          | <code>SQLCOM_PREPARE</code>            |
| <code>EXECUTE</code>                          | <code>SQLCOM_EXECUTE</code>            |
| <code>DEALLOCATE PREPARE, DROP PREPARE</code> | <code>SQLCOM DEALLOCATE PREPARE</code> |

Performance Schema prepared statement instrumentation covers both protocols. The following discussion refers to the server commands rather than the C API functions or SQL statements.

Information about prepared statements is available in the `prepared_statements_instances` table. This table enables inspection of prepared statements used in the server and provides aggregated statistics about them. To control the size of this table, set the `performance_schema_max_prepared_statements_instances` system variable at server startup.

Collection of prepared statement information depends on the statement instruments shown in the following table. These instruments are enabled by default. To modify them, update the `setup_instruments` table.

| Instrument                             | Server Command                |
|----------------------------------------|-------------------------------|
| <code>statement/com/Prepare</code>     | <code>COM_STMT_PREPARE</code> |
| <code>statement/com/Execute</code>     | <code>COM_STMT_EXECUTE</code> |
| <code>statement/sql/prepare_sql</code> | <code>SQLCOM_PREPARE</code>   |
| <code>statement/sql/execute_sql</code> | <code>SQLCOM_EXECUTE</code>   |

The Performance Schema manages the contents of the `prepared_statements_instances` table as follows:

- Statement preparation

A `COM_STMT_PREPARE` or `SQLCOM_PREPARE` command creates a prepared statement in the server. If the statement is successfully instrumented, a new row is added to the `prepared_statements_instances` table. If the statement cannot be instrumented, `Performance_schema_prepared_statements_lost` status variable is incremented.

- Prepared statement execution

Execution of a `COM_STMT_EXECUTE` or `SQLCOM_EXECUTE` command for an instrumented prepared statement instance updates the corresponding `prepared_statements_instances` table row.

- Prepared statement deallocation

Execution of a `COM_STMT_CLOSE` or `SQLCOM DEALLOCATE_PREPARE` command for an instrumented prepared statement instance removes the corresponding `prepared_statements_instances` table row. To avoid resource leaks, removal occurs even if the prepared statement instruments described previously are disabled.

The `prepared_statements_instances` table has these columns:

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented prepared statement.

- `STATEMENT_ID`

The internal statement ID assigned by the server. The text and binary protocols both use statement IDs.

- `STATEMENT_NAME`

For the binary protocol, this column is `NULL`. For the text protocol, this column is the external statement name assigned by the user. For example, for the following SQL statement, the name of the prepared statement is `stmt`:

```
PREPARE stmt FROM 'SELECT 1';
```

- `SQL_TEXT`

The prepared statement text, with `?` placeholder markers.

- `OWNER_THREAD_ID`, `OWNER_EVENT_ID`

These columns indicate the event that created the prepared statement.

- `OWNER_OBJECT_TYPE`, `OWNER_OBJECT_SCHEMA`, `OWNER_OBJECT_NAME`

For a prepared statement created by a client session, these columns are `NULL`. For a prepared statement created by a stored program, these columns point to the stored program. A typical user error is forgetting to deallocate prepared statements. These columns can be used to find stored programs that leak prepared statements:

```
SELECT
 OWNER_OBJECT_TYPE, OWNER_OBJECT_SCHEMA, OWNER_OBJECT_NAME,
 STATEMENT_NAME, SQL_TEXT
FROM performance_schema.prepared_statements_instances
WHERE OWNER_OBJECT_TYPE IS NOT NULL;
```

- `TIMER_PREPARE`

The time spent executing the statement preparation itself.

- `COUNT_REPREPARE`

The number of times the statement was reprepared internally (see [Section 8.10.4, “Caching of Prepared Statements and Stored Programs”](#)). Timing statistics for repreparation are not available because it is counted as part of statement execution, not as a separate operation.

- `COUNT_EXECUTE`, `SUM_TIMER_EXECUTE`, `MIN_TIMER_EXECUTE`, `AVG_TIMER_EXECUTE`, `MAX_TIMER_EXECUTE`

Aggregated statistics for executions of the prepared statement.

- `SUM_xxx`

The remaining `SUM_xxx` columns are the same as for the statement summary tables (see [Section 25.12.15.3, “Statement Summary Tables”](#)).

`TRUNCATE TABLE` resets the statistics columns of the `prepared_statements_instances` table.

## 25.12.7 Performance Schema Transaction Tables

The Performance Schema instruments transactions. Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store transaction events:

- `events_transactions_current`: The current transaction event for each thread.
- `events_transactions_history`: The most recent transaction events that have ended per thread.
- `events_transactions_history_long`: The most recent transaction events that have ended globally (across all threads).

The following sections describe the transaction event tables. There are also summary tables that aggregate information about transaction events; see [Section 25.12.15.4, “Transaction Summary Tables”](#).

For more information about the relationship between the three transaction event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

- [Configuring Transaction Event Collection](#)
- [Transaction Boundaries](#)
- [Transaction Instrumentation](#)
- [Transactions and Nested Events](#)
- [Transactions and Stored Programs](#)
- [Transactions and Savepoints](#)
- [Transactions and Errors](#)

### Configuring Transaction Event Collection

To control whether to collect transaction events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains an instrument named `transaction`. Use this instrument to enable or disable collection of individual transaction event classes.
- The `setup_consumers` table contains consumer values with names corresponding to the current and historical transaction event table names. Use these consumers to filter collection of transaction events.

The `transaction` instrument and the transaction consumers are disabled by default:

```
mysql> SELECT *
 FROM performance_schema.setup_instruments
 WHERE NAME = 'transaction';
+-----+-----+-----+
| NAME | ENABLED | TIMED |
+-----+-----+-----+
| transaction | NO | NO |
+-----+-----+-----+
mysql> SELECT *
 FROM performance_schema.setup_consumers
 WHERE NAME LIKE 'events_transactions%';
+-----+-----+
| NAME | ENABLED |
+-----+-----+
| events_transactions_current | NO |
| events_transactions_history | NO |
| events_transactions_history_long | NO |
+-----+-----+
```

To control transaction event collection at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='transaction=ON'
performance-schema-consumer-events-transactions-current=ON
performance-schema-consumer-events-transactions-history=ON
performance-schema-consumer-events-transactions-history-long=ON
```

- Disable:

```
[mysqld]
performance-schema-instrument='transaction=OFF'
performance-schema-consumer-events-transactions-current=OFF
performance-schema-consumer-events-transactions-history=OFF
performance-schema-consumer-events-transactions-history-long=OFF
```

To control transaction event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- Enable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME = 'transaction';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE 'events_transactions%';
```

- Disable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME = 'transaction';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE 'events_transactions%';
```

To collect transaction events only for specific transaction event tables, enable the `transaction` instrument but only the transaction consumers corresponding to the desired tables.

The `setup_timers` table contains a row with a `NAME` value of `transaction` that indicates the unit for transaction event timing. The default unit is `NANOSECOND`:

```
mysql> SELECT *
```

```
FROM performance_schema.setup_timers
WHERE NAME = 'transaction';
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| transaction | NANOSECOND |
+-----+-----+
```

To change the timing unit, modify the `TIMER_NAME` value:

```
UPDATE performance_schema.setup_timers
SET TIMER_NAME = 'MICROSECOND'
WHERE NAME = 'transaction';
```

For additional information about configuring event collection, see [Section 25.3, “Performance Schema Startup Configuration”](#), and [Section 25.4, “Performance Schema Runtime Configuration”](#).

## Transaction Boundaries

In MySQL Server, transactions start explicitly with these statements:

```
START TRANSACTION | BEGIN | XA START | XA BEGIN
```

Transactions also start implicitly. For example, when the `autocommit` system variable is enabled, the start of each statement starts a new transaction.

When `autocommit` is disabled, the first statement following a committed transaction marks the start of a new transaction. Subsequent statements are part of the transaction until it is committed.

Transactions explicitly end with these statements:

```
COMMIT | ROLLBACK | XA COMMIT | XA ROLLBACK
```

Transactions also end implicitly, by execution of DDL statements, locking statements, and server administration statements.

In the following discussion, references to `START TRANSACTION` also apply to `BEGIN`, `XA START`, and `XA BEGIN`. Similarly, references to `COMMIT` and `ROLLBACK` apply to `XA COMMIT` and `XA ROLLBACK`, respectively.

The Performance Schema defines transaction boundaries similarly to that of the server. The start and end of a transaction event closely match the corresponding state transitions in the server:

- For an explicitly started transaction, the transaction event starts during processing of the `START TRANSACTION` statement.
- For an implicitly started transaction, the transaction event starts on the first statement that uses a transactional engine after the previous transaction has ended.
- For any transaction, whether explicitly or implicitly ended, the transaction event ends when the server transitions out of the active transaction state during the processing of `COMMIT` or `ROLLBACK`.

There are subtle implications to this approach:

- Transaction events in the Performance Schema do not fully include the statement events associated with the corresponding `START TRANSACTION`, `COMMIT`, or `ROLLBACK` statements. There is a trivial amount of timing overlap between the transaction event and these statements.
- Statements that work with nontransactional engines have no effect on the transaction state of the connection. For implicit transactions, the transaction event begins with the first statement that uses a transactional engine. This means that statements operating exclusively on nontransactional tables are ignored, even following `START TRANSACTION`.

To illustrate, consider the following scenario:

```

1. SET autocommit = OFF;
2. CREATE TABLE t1 (a INT) ENGINE = InnoDB;
3. START TRANSACTION; -- Transaction 1 START
4. INSERT INTO t1 VALUES (1), (2), (3);
5. CREATE TABLE t2 (a INT) ENGINE = MyISAM; -- Transaction 1 COMMIT
 -- (implicit; DDL forces commit)
6. INSERT INTO t2 VALUES (1), (2), (3); -- Update nontransactional table
7. UPDATE t2 SET a = a + 1; -- ... and again
8. INSERT INTO t1 VALUES (4), (5), (6); -- Write to transactional table
 -- Transaction 2 START (implicit)
9. COMMIT; -- Transaction 2 COMMIT

```

From the perspective of the server, Transaction 1 ends when table `t2` is created. Transaction 2 does not start until a transactional table is accessed, despite the intervening updates to nontransactional tables.

From the perspective of the Performance Schema, Transaction 2 starts when the server transitions into an active transaction state. Statements 6 and 7 are not included within the boundaries of Transaction 2, which is consistent with how the server writes transactions to the binary log.

## Transaction Instrumentation

Three attributes define transactions:

- Access mode (read only, read write)
- Isolation level (`SERIALIZABLE`, `REPEATABLE READ`, and so forth)
- Implicit (`autocommit` enabled) or explicit (`autocommit` disabled)

To reduce complexity of the transaction instrumentation and to ensure that the collected transaction data provides complete, meaningful results, all transactions are instrumented independently of access mode, isolation level, or autocommit mode.

To selectively examine transaction history, use the attribute columns in the transaction event tables: `ACCESS_MODE`, `ISOLATION_LEVEL`, and `AUTOCOMMIT`.

The cost of transaction instrumentation can be reduced various ways, such as enabling or disabling transaction instrumentation according to user, account, host, or thread (client connection).

## Transactions and Nested Events

The parent of a transaction event is the event that initiated the transaction. For an explicitly started transaction, this includes the `START TRANSACTION` and `COMMIT AND CHAIN` statements. For an implicitly started transaction, it is the first statement that uses a transactional engine after the previous transaction ends.

In general, a transaction is the top-level parent to all events initiated during the transaction, including statements that explicitly end the transaction such as `COMMIT` and `ROLLBACK`. Exceptions are statements that implicitly end a transaction, such as DDL statements, in which case the current transaction must be committed before the new statement is executed.

## Transactions and Stored Programs

Transactions and stored program events are related as follows:

- Stored Procedures

Stored procedures operate independently of transactions. A stored procedure can be started within a transaction, and a transaction can be started or ended from within a stored procedure. If called from

within a transaction, a stored procedure can execute statements that force a commit of the parent transaction and then start a new transaction.

If a stored procedure is started within a transaction, that transaction is the parent of the stored procedure event.

If a transaction is started by a stored procedure, the stored procedure is the parent of the transaction event.

- **Stored Functions**

Stored functions are restricted from causing an explicit or implicit commit or rollback. Stored function events can reside within a parent transaction event.

- **Triggers**

Triggers activate as part of a statement that accesses the table with which it is associated, so the parent of a trigger event is always the statement that activates it.

Triggers cannot issue statements that cause an explicit or implicit commit or rollback of a transaction.

- **Scheduled Events**

The execution of the statements in the body of a scheduled event takes place in a new connection. Nesting of a scheduled event within a parent transaction is not applicable.

## Transactions and Savepoints

Savepoint statements are recorded as separate statement events. Transaction events include separate counters for `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, and `RELEASE SAVEPOINT` statements issued during the transaction.

## Transactions and Errors

Errors and warnings that occur within a transaction are recorded in statement events, but not in the corresponding transaction event. This includes transaction-specific errors and warnings, such as a rollback on a nontransactional table or GTID consistency errors.

### 25.12.7.1 The `events_transactions_current` Table

The `events_transactions_current` table contains current transaction events. The table stores one row per thread showing the current status of the thread's most recent monitored transaction event, so there is no system variable for configuring the table size. For example:

```
mysql> SELECT *
 FROM performance_schema.events_transactions_current LIMIT 1\G

 1. row ****
 THREAD_ID: 26
 EVENT_ID: 7
 END_EVENT_ID: NULL
 EVENT_NAME: transaction
 STATE: ACTIVE
 TRX_ID: NULL
 GTID: 3E11FA47-71CA-11E1-9E33-C80AA9429562:56
 XID: NULL
 XA_STATE: NULL
 SOURCE: transaction.cc:150
 TIMER_START: 420833537900000
 TIMER_END: NULL
 TIMER_WAIT: NULL
 ACCESS_MODE: READ WRITE
 ISOLATION_LEVEL: REPEATABLE READ
 AUTOCOMMIT: NO
 NUMBER_OF_SAVEPOINTS: 0
```

```

NUMBER_OF_ROLLBACK_TO_SAVEPOINT: 0
NUMBER_OF_RELEASE_SAVEPOINT: 0
OBJECT_INSTANCE_BEGIN: NULL
NESTING_EVENT_ID: 6
NESTING_EVENT_TYPE: STATEMENT

```

Of the tables that contain transaction event rows, `events_transactions_current` is the most fundamental. Other tables that contain transaction event rows are logically derived from the current events. For example, the `events_transactions_history` and `events_transactions_history_long` tables are collections of the most recent transaction events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three transaction event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect transaction events, see [Section 25.12.7, “Performance Schema Transaction Tables”](#).

The `events_transactions_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument from which the event was collected. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

- `STATE`

The current transaction state. The value is `ACTIVE` (after `START TRANSACTION` or `BEGIN`), `COMMITTED` (after `COMMIT`), or `ROLLED BACK` (after `ROLLBACK`).

- `TRX_ID`

Unused.

- `GTID`

The GTID column contains the value of `gtid_next`, which can be one of `ANONYMOUS`, `AUTOMATIC`, or a GTID using the format `UUID:NUMBER`. For transactions that use `gtid_next=AUTOMATIC`, which is all normal client transactions, the GTID column changes when the transaction commits and the actual GTID is assigned. If `gtid_mode` is either `ON` or `ON_PERMISSIVE`, the GTID column changes to the transaction's GTID. If `gtid_mode` is either `OFF` or `OFF_PERMISSIVE`, the GTID column changes to `ANONYMOUS`.

- `XID_FORMAT_ID`, `XID_GTRID`, and `XID_BQUAL`

The elements of the XA transaction identifier. They have the format described in [Section 13.3.7.1, “XA Transaction SQL Statements”](#).

- `XA_STATE`

The state of the XA transaction. The value is `ACTIVE` (after `XA START`), `IDLE` (after `XA END`), `PREPARED` (after `XA PREPARE`), `ROLLED BACK` (after `XA ROLLBACK`), or `COMMITTED` (after `XA COMMIT`).

On a replica, the same XA transaction can appear in the `events_transactions_current` table with different states on different threads. This is because immediately after the XA transaction is prepared, it is detached from the replication applier thread, and can be committed or rolled back by any thread on the replica. The `events_transactions_current` table displays the current status of the most recent monitored transaction event on the thread, and does not update this status when the thread is idle. So the XA transaction can still be displayed in the `PREPARED` state for the original applier thread, after it has been processed by another thread. To positively identify XA transactions that are still in the `PREPARED` state and need to be recovered, use the `XA RECOVER` statement rather than the Performance Schema transaction tables.

- **SOURCE**

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- **TIMER\_START, TIMER\_END, TIMER\_WAIT**

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 25.4.1, “Performance Schema Event Timing”](#).

- **ACCESS\_MODE**

The transaction access mode. The value is `READ WRITE` or `READ ONLY`.

- **ISOLATION\_LEVEL**

The transaction isolation level. The value is `REPEATABLE READ`, `READ COMMITTED`, `READ UNCOMMITTED`, or `SERIALIZABLE`.

- **AUTOCOMMIT**

Whether autocommit mode was enabled when the transaction started.

- **NUMBER\_OF\_SAVEPOINTS, NUMBER\_OF\_ROLLBACK\_TO\_SAVEPOINT, NUMBER\_OF\_RELEASE\_SAVEPOINT**

The number of `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, and `RELEASE SAVEPOINT` statements issued during the transaction.

- **OBJECT\_INSTANCE\_BEGIN**

Unused.

- **NESTING\_EVENT\_ID**

The `EVENT_ID` value of the event within which this event is nested.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`. (`TRANSACTION` does not appear because transactions cannot be nested.)

`TRUNCATE TABLE` is permitted for the `events_transactions_current` table. It removes the rows.

### 25.12.7.2 The `events_transactions_history` Table

The `events_transactions_history` table contains the `N` most recent transaction events that have ended per thread. Transaction events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of `N` during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_transactions_history_size` system variable at server startup.

The `events_transactions_history` table has the same columns as `events_transactions_current`. See [Section 25.12.7.1, “The `events\_transactions\_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_transactions_history` table. It removes the rows.

For more information about the relationship between the three transaction event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect transaction events, see [Section 25.12.7, “Performance Schema Transaction Tables”](#).

### 25.12.7.3 The `events_transactions_history_long` Table

The `events_transactions_history_long` table contains the `N` most recent transaction events that have ended globally, across all threads. Transaction events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The Performance Schema autosizes the value of `N` is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_transactions_history_long_size` system variable at server startup.

The `events_transactions_history_long` table has the same columns as `events_transactions_current`. See [Section 25.12.7.1, “The `events\_transactions\_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_transactions_history_long` table. It removes the rows.

For more information about the relationship between the three transaction event tables, see [Section 25.9, “Performance Schema Tables for Current and Historical Events”](#).

For information about configuring whether to collect transaction events, see [Section 25.12.7, “Performance Schema Transaction Tables”](#).

## 25.12.8 Performance Schema Connection Tables

When a client connects to the MySQL server, it does so under a particular user name and from a particular host. The Performance Schema provides statistics about these connections, tracking them per account (user and host combination) as well as separately per user name and host name, using these tables:

- `accounts`: Connection statistics per client account

- `hosts`: Connection statistics per client host name
- `users`: Connection statistics per client user name

The meaning of “account” in the connection tables is similar to its meaning in the MySQL grant tables in the `mysql` system database, in the sense that the term refers to a combination of user and host values. They differ in that, for grant tables, the host part of an account can be a pattern, whereas for Performance Schema tables, the host value is always a specific nonpattern host name.

Each connection table has `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns to track the current and total number of connections per “tracking value” on which its statistics are based. The tables differ in what they use for the tracking value. The `accounts` table has `USER` and `HOST` columns to track connections per user and host combination. The `users` and `hosts` tables have a `USER` and `HOST` column, respectively, to track connections per user name and host name.

The Performance Schema also counts internal threads and threads for user sessions that failed to authenticate, using rows with `USER` and `HOST` column values of `NULL`.

Suppose that clients named `user1` and `user2` each connect one time from `hosta` and `hostb`. The Performance Schema tracks the connections as follows:

- The `accounts` table has four rows, for the `user1/hosta`, `user1/hostb`, `user2/hosta`, and `user2/hostb` account values, each row counting one connection per account.
- The `hosts` table has two rows, for `hosta` and `hostb`, each row counting two connections per host name.
- The `users` table has two rows, for `user1` and `user2`, each row counting two connections per user name.

When a client connects, the Performance Schema determines which row in each connection table applies, using the tracking value appropriate to each table. If there is no such row, one is added. Then the Performance Schema increments by one the `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns in that row.

When a client disconnects, the Performance Schema decrements by one the `CURRENT_CONNECTIONS` column in the row and leaves the `TOTAL_CONNECTIONS` column unchanged.

`TRUNCATE TABLE` is permitted for connection tables. It has these effects:

- Rows are removed for accounts, hosts, or users that have no current connections (rows with `CURRENT_CONNECTIONS = 0`).
- Nonremoved rows are reset to count only current connections: For rows with `CURRENT_CONNECTIONS > 0`, `TOTAL_CONNECTIONS` is reset to `CURRENT_CONNECTIONS`.
- Summary tables that depend on the connection table are implicitly truncated, as described later in this section.

The Performance Schema maintains summary tables that aggregate connection statistics for various event types by account, host, or user. These tables have `_summary_by_account`, `_summary_by_host`, or `_summary_by_user` in the name. To identify them, use this query:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
 WHERE TABLE_SCHEMA = 'performance_schema'
 AND TABLE_NAME REGEXP '_summary_by_(account|host|user)'
 ORDER BY TABLE_NAME;
+-----+
| TABLE_NAME |
+-----+
| events_stages_summary_by_account_by_event_name |
| events_stages_summary_by_host_by_event_name |
+-----+
```

```

| events_stages_summary_by_user_by_event_name
| events_statements_summary_by_account_by_event_name
| events_statements_summary_by_host_by_event_name
| events_statements_summary_by_user_by_event_name
| events_transactions_summary_by_account_by_event_name
| events_transactions_summary_by_host_by_event_name
| events_transactions_summary_by_user_by_event_name
| events_waits_summary_by_account_by_event_name
| events_waits_summary_by_host_by_event_name
| events_waits_summary_by_user_by_event_name
| memory_summary_by_account_by_event_name
| memory_summary_by_host_by_event_name
| memory_summary_by_user_by_event_name
+-----+

```

For details about individual connection summary tables, consult the section that describes tables for the summarized event type:

- Wait event summaries: [Section 25.12.15.1, “Wait Event Summary Tables”](#)
- Stage event summaries: [Section 25.12.15.2, “Stage Summary Tables”](#)
- Statement event summaries: [Section 25.12.15.3, “Statement Summary Tables”](#)
- Transaction event summaries: [Section 25.12.15.4, “Transaction Summary Tables”](#)
- Memory event summaries: [Section 25.12.15.9, “Memory Summary Tables”](#)

`TRUNCATE TABLE` is permitted for connection summary tables. It removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows. In addition, each summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends. The following table describes the relationship between connection table truncation and implicitly truncated tables.

**Table 25.2 Implicit Effects of Connection Table Truncation**

| Truncated Connection Table | Implicitly Truncated Summary Tables                                                                                             |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>accounts</code>      | Tables with names containing <code>_summary_by_account</code> , <code>_summary_by_thread</code>                                 |
| <code>hosts</code>         | Tables with names containing <code>_summary_by_account</code> , <code>_summary_by_host</code> , <code>_summary_by_thread</code> |
| <code>users</code>         | Tables with names containing <code>_summary_by_account</code> , <code>_summary_by_user</code> , <code>_summary_by_thread</code> |

Truncating a `_summary_global` summary table also implicitly truncates its corresponding connection and thread summary tables. For example, truncating `events_waits_summary_global_by_event_name` implicitly truncates the wait event summary tables that are aggregated by account, host, user, or thread.

### 25.12.8.1 The `accounts` Table

The `accounts` table contains a row for each account that has connected to the MySQL server. For each account, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_accounts_size` system variable at server startup. To disable account statistics, set this variable to 0.

The `accounts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 25.12.8, “Performance Schema Connection Tables”](#).

- `USER`

The client user name for the connection. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `HOST`

The host from which the client connected. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `CURRENT_CONNECTIONS`

The current number of connections for the account.

- `TOTAL_CONNECTIONS`

The total number of connections for the account.

### 25.12.8.2 The hosts Table

The `hosts` table contains a row for each host from which clients have connected to the MySQL server. For each host name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_hosts_size` system variable at server startup. To disable host statistics, set this variable to 0.

The `hosts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 25.12.8, “Performance Schema Connection Tables”](#).

- `HOST`

The host from which the client connected. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `CURRENT_CONNECTIONS`

The current number of connections for the host.

- `TOTAL_CONNECTIONS`

The total number of connections for the host.

### 25.12.8.3 The users Table

The `users` table contains a row for each user who has connected to the MySQL server. For each user name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_users_size` system variable at server startup. To disable user statistics, set this variable to 0.

The `users` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 25.12.8, “Performance Schema Connection Tables”](#).

- `USER`

The client user name for the connection. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `CURRENT_CONNECTIONS`

The current number of connections for the user.

- `TOTAL_CONNECTIONS`

The total number of connections for the user.

## 25.12.9 Performance Schema Connection Attribute Tables

Connection attributes are key-value pairs that application programs can pass to the server at connect time. For applications based on the C API implemented by the `libmysqlclient` client library, the `mysql_options()` and `mysql_options4()` functions define the connection attribute set. Other MySQL Connectors may provide their own attribute-definition methods.

These Performance Schema tables expose attribute information:

- `session_account_connect_attrs`: Connection attributes for the current session, and other sessions associated with the session account
- `session_connect_attrs`: Connection attributes for all sessions

Attribute names that begin with an underscore (`_`) are reserved for internal use and should not be created by application programs. This convention permits new attributes to be introduced by MySQL without colliding with application attributes, and enables application programs to define their own attributes that do not collide with internal attributes.

- [Available Connection Attributes](#)
- [Connection Attribute Limits](#)

### Available Connection Attributes

The set of connection attributes visible within a given connection varies depending on factors such as your platform, MySQL Connector used to establish the connection, or client program.

The `libmysqlclient` client library sets these attributes:

- `_client_name`: The client name (`libmysql` for the client library).
- `_client_version`: The client library version.
- `_os`: The operating system (for example, `Linux`, `Win64`).
- `_pid`: The client process ID.
- `_platform`: The machine platform (for example, `x86_64`).
- `_thread`: The client thread ID (Windows only).

Other MySQL Connectors may define their own connection attributes.

MySQL Connector/J defines these attributes:

- `_client_license`: The connector license type.
- `_runtime_vendor`: The Java runtime environment (JRE) vendor.
- `_runtime_version`: The Java runtime environment (JRE) version.

MySQL Connector/.NET defines these attributes:

- `_client_version`: The client library version.
- `_os`: The operating system (for example, `Linux`, `Win64`).

- `_pid`: The client process ID.
- `_platform`: The machine platform (for example, `x86_64`).
- `_program_name`: The client name.
- `_thread`: The client thread ID (Windows only).

PHP defines attributes that depend on how it was compiled:

- Compiled using `libmysqlclient`: The standard `libmysqlclient` attributes, described previously.
- Compiled using `mysqlnd`: Only the `_client_name` attribute, with a value of `mysqlnd`.

Many MySQL client programs set a `program_name` attribute with a value equal to the client name. For example, `mysqladmin` and `mysqldump` set `program_name` to `mysqladmin` and `mysqldump`, respectively.

Some MySQL client programs define additional attributes:

- `mysqlbinlog`:
  - `_client_role: binary_log_listener`
- Replica connections:
  - `program_name: mysqld`
  - `_client_role: binary_log_listener`
  - `_client_replication_channel_name`: The channel name.
- `FEDERATED` storage engine connections:
  - `program_name: mysqld`
  - `_client_role: federated_storage`

## Connection Attribute Limits

There are limits on the amount of connection attribute data transmitted from client to server:

- A fixed limit imposed by the client prior to connect time.
- A fixed limit imposed by the server at connect time.
- A configurable limit imposed by the Performance Schema at connect time.

For connections initiated using the C API, the `libmysqlclient` library imposes a limit of 64KB on the aggregate size of connection attribute data on the client side: Calls to `mysql_options()` that cause this limit to be exceeded produce a `CR_INVALID_PARAMETER_NO` error. Other MySQL Connectors may impose their own client-side limits on how much connection attribute data can be transmitted to the server.

On the server side, these size checks on connection attribute data occur:

- The server imposes a limit of 64KB on the aggregate size of connection attribute data it can accept. If a client attempts to send more than 64KB of attribute data, the server rejects the connection.
- For accepted connections, the Performance Schema checks aggregate attribute size against the value of the `performance_schema_session_connect_attrs_size` system variable. If attribute size exceeds this value, these actions take place:

- The Performance Schema truncates the attribute data and increments the `Performance_schema_session_connect_attrs_lost` status variable, which indicates the number of connections for which attribute truncation occurred.
- The Performance Schema writes a message to the error log if the `log_error_verbosity` system variable is greater than 1:

```
[Warning] Connection attributes of length N were truncated
```

### 25.12.9.1 The `session_account_connect_attrs` Table

Application programs can provide key-value connection attributes to be passed to the server at connect time. For descriptions of common attributes, see [Section 25.12.9, “Performance Schema Connection Attribute Tables”](#).

The `session_account_connect_attrs` table contains connection attributes only for the current session, and other sessions associated with the session account. To see connection attributes for all sessions, use the `session_connect_attrs` table.

The `session_account_connect_attrs` table has these columns:

- `PROCESSLIST_ID`

The connection identifier for the session.

- `ATTR_NAME`

The attribute name.

- `ATTR_VALUE`

The attribute value.

- `ORDINAL_POSITION`

The order in which the attribute was added to the set of connection attributes.

`TRUNCATE TABLE` is not permitted for the `session_account_connect_attrs` table.

### 25.12.9.2 The `session_connect_attrs` Table

Application programs can provide key-value connection attributes to be passed to the server at connect time. For descriptions of common attributes, see [Section 25.12.9, “Performance Schema Connection Attribute Tables”](#).

The `session_connect_attrs` table contains connection attributes for all sessions. To see connection attributes only for the current session, and other sessions associated with the session account, use the `session_account_connect_attrs` table.

The `session_connect_attrs` table has these columns:

- `PROCESSLIST_ID`

The connection identifier for the session.

- `ATTR_NAME`

The attribute name.

- `ATTR_VALUE`

The attribute value.

- `ORDINAL_POSITION`

The order in which the attribute was added to the set of connection attributes.

`TRUNCATE TABLE` is not permitted for the `session_connect_attrs` table.

## 25.12.10 Performance Schema User-Defined Variable Tables

The Performance Schema provides a `user_variables_by_thread` table that exposes user-defined variables. These are variables defined within a specific session and include a @ character preceding the name; see [Section 9.4, “User-Defined Variables”](#).

The `user_variables_by_thread` table has these columns:

- `THREAD_ID`

The thread identifier of the session in which the variable is defined.

- `VARIABLE_NAME`

The variable name, without the leading @ character.

- `VARIABLE_VALUE`

The variable value.

`TRUNCATE TABLE` is not permitted for the `user_variables_by_thread` table.

## 25.12.11 Performance Schema Replication Tables

The Performance Schema provides tables that expose replication information. This is similar to the information available from the `SHOW SLAVE STATUS` statement, but representation in table form is more accessible and has usability benefits:

- `SHOW SLAVE STATUS` output is useful for visual inspection, but not so much for programmatic use. By contrast, using the Performance Schema tables, information about replica status can be searched using general `SELECT` queries, including complex `WHERE` conditions, joins, and so forth.
- Query results can be saved in tables for further analysis, or assigned to variables and thus used in stored procedures.
- The replication tables provide better diagnostic information. For multithreaded replica operation, `SHOW SLAVE STATUS` reports all coordinator and worker thread errors using the `Last_SQL_Errno` and `Last_SQL_Error` fields, so only the most recent of those errors is visible and information can be lost. The replication tables store errors on a per-thread basis without loss of information.
- The last seen transaction is visible in the replication tables on a per-worker basis. This is information not available from `SHOW SLAVE STATUS`.
- Developers familiar with the Performance Schema interface can extend the replication tables to provide additional information by adding rows to the tables.

## Replication Table Descriptions

The Performance Schema provides the following replication-related tables:

- Tables that contain information about the connection of a replica to the replication source server:
  - `replication_connection_configuration`: Configuration parameters for connecting to the source
  - `replication_connection_status`: Current status of the connection to the source

- Tables that contain general (not thread-specific) information about the transaction applier:
  - `replication_applier_configuration`: Configuration parameters for the transaction applier on the replica.
  - `replication_applier_status`: Current status of the transaction applier on the replica.
- Tables that contain information about specific threads responsible for applying transactions received from the source:
  - `replication_applier_status_by_coordinator`: Status of the coordinator thread (empty unless the replica is multithreaded).
  - `replication_applier_status_by_worker`: Status of the applier thread or worker threads if the replica is multithreaded.
- Tables that contain information about replication group members:
  - `replication_group_members`: Provides network and status information for group members.
  - `replication_group_member_stats`: Provides statistical information about group members and transaction in which they participate.

The following sections describe each replication table in more detail, including the correspondence between the columns produced by `SHOW SLAVE STATUS` and the replication table columns in which the same information appears.

The remainder of this introduction to the replication tables describes how the Performance Schema populates them and which fields from `SHOW SLAVE STATUS` are not represented in the tables.

## Replication Table Life Cycle

The Performance Schema populates the replication tables as follows:

- Prior to execution of `CHANGE MASTER TO`, the tables are empty.
- After `CHANGE MASTER TO`, the configuration parameters can be seen in the tables. At this time, there are no active replica threads, so the `THREAD_ID` columns are `NULL` and the `SERVICE_STATE` columns have a value of `OFF`.
- After `START SLAVE`, non-`NULL` `THREAD_ID` values can be seen. Threads that are idle or active have a `SERVICE_STATE` value of `ON`. The thread that connects to the source has a value of `CONNECTING` while it establishes the connection, and `ON` thereafter as long as the connection lasts.
- After `STOP SLAVE`, the `THREAD_ID` columns become `NULL` and the `SERVICE_STATE` columns for threads that no longer exist have a value of `OFF`.
- The tables are preserved after `STOP SLAVE` or threads dying due to an error.
- The `replication_applier_status_by_worker` table is nonempty only when the replica is operating in multithreaded mode. That is, if the `slave_parallel_workers` system variable is greater than 0, this table is populated when `START SLAVE` is executed, and the number of rows shows the number of workers.

## `SHOW SLAVE STATUS` Information Not In the Replication Tables

The information in the Performance Schema replication tables differs somewhat from the information available from `SHOW SLAVE STATUS` because the tables are oriented toward use of global transaction identifiers (GTIDs), not file names and positions, and they represent server UUID values, not server ID values. Due to these differences, several `SHOW SLAVE STATUS` columns are not preserved in the Performance Schema replication tables, or are represented a different way:

- The following fields refer to file names and positions and are not preserved:

```
Master_Log_File
Read_Master_Log_Pos
Relay_Log_File
Relay_Log_Pos
Relay_Master_Log_File
Exec_Master_Log_Pos
Until_Condition
Until_Log_File
Until_Log_Pos
```

- The `Master_Info_File` field is not preserved. It refers to the `master.info` file, which has been superseded by crash-safe tables.

- The following fields are based on `server_id`, not `server_uuid`, and are not preserved:

```
Master_Server_Id
Replicate_Ignore_Servers
```

- The `Skip_Counter` field is based on event counts, not GTIDs, and is not preserved.
- These error fields are aliases for `Last_SQL_Errno` and `Last_SQL_Error`, so they are not preserved:

```
Last_Errno
Last_Error
```

In the Performance Schema, this error information is available in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns of the `replication_applier_status_by_worker` table (and `replication_applier_status_by_coordinator` if the replica is multithreaded). Those tables provide more specific per-thread error information than is available from `Last_Errno` and `Last_Error`.

- Fields that provide information about command-line filtering options is not preserved:

```
Replicate_Do_DB
Replicate_Ignore_DB
Replicate_Do_Table
Replicate_Ignore_Table
Replicate_Wild_Do_Table
Replicate_Wild_Ignore_Table
```

- The `Slave_IO_State` and `Slave_SQL_Running_State` fields are not preserved. If needed, these values can be obtained from the process list by using the `THREAD_ID` column of the appropriate replication table and joining it with the `ID` column in the `INFORMATION_SCHEMA PROCESSLIST` table to select the `STATE` column of the latter table.
- The `Executed_Gtid_Set` field can show a large set with a great deal of text. Instead, the Performance Schema tables show GTIDs of transactions that are currently being applied by the replica. Alternatively, the set of executed GTIDs can be obtained from the value of the `gtid_executed` system variable.
- The `Seconds_Behind_Master` and `Relay_Log_Space` fields are in to-be-decided status and are not preserved.

## Status Variables Moved to Replication Tables

As of MySQL version 5.7.5, the following status variables (previously monitored using `SHOW STATUS`) were moved to the Performance Schema replication tables:

- `Slave_retried_transactions`
- `Slave_last_heartbeat`
- `Slave_received_heartbeats`

- `Slave_heartbeat_period`
- `Slave_running`

These status variables are now only relevant when a single replication channel is being used because they *only* report the status of the default replication channel. When multiple replication channels exist, use the Performance Schema replication tables described in this section, which report these variables for each existing replication channel.

## Replication Channels

The first column of the replication Performance Schema tables is `CHANNEL_NAME`. This enables the tables to be viewed per replication channel. In a non-multisource replication setup there is a single default replication channel. When you are using multiple replication channels on a replica, you can filter the tables per replication channel to monitor a specific replication channel. See [Section 16.2.2, “Replication Channels”](#) and [Section 16.1.5.8, “Multi-Source Replication Monitoring”](#) for more information.

### 25.12.11.1 The `replication_connection_configuration` Table

This table shows the configuration parameters used by the replica for connecting to the source. Parameters stored in the table can be changed at runtime with the `CHANGE MASTER TO` statement, as indicated in the column descriptions.

Compared to the `replication_connection_status` table, `replication_connection_configuration` changes less frequently. It contains values that define how the replica connects to the source and that remain constant during the connection, whereas `replication_connection_status` contains values that change during the connection.

The `replication_connection_configuration` table has the following columns. The column descriptions indicate the corresponding `CHANGE MASTER TO` options from which the column values are taken, and the table given later in this section shows the correspondence between `replication_connection_configuration` columns and `SHOW SLAVE STATUS` columns.

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 16.2.2, “Replication Channels”](#) for more information. (`CHANGE MASTER TO` option: `FOR CHANNEL`)

- `HOST`

The replication source server that the replica is connected to. (`CHANGE MASTER TO` option: `MASTER_HOST`)

- `PORT`

The port used to connect to the replication source server. (`CHANGE MASTER TO` option: `MASTER_PORT`)

- `USER`

The user name of the account used to connect to the replication source server. (`CHANGE MASTER TO` option: `MASTER_USER`)

- `NETWORK_INTERFACE`

The network interface that the replica is bound to, if any. (`CHANGE MASTER TO` option: `MASTER_BIND`)

- `AUTO_POSITION`

1 if autopositioning is in use; otherwise 0. ([CHANGE MASTER TO option: MASTER\\_AUTO\\_POSITION](#))

- `SSL_ALLOWED`, `SSL_CA_FILE`, `SSL_CA_PATH`, `SSL_CERTIFICATE`, `SSL_CIPHER`, `SSL_KEY`, `SSL_VERIFY_SERVER_CERTIFICATE`, `SSL_CRL_FILE`, `SSL_CRL_PATH`

These columns show the SSL parameters used by the replica to connect to the replication source server, if any.

`SSL_ALLOWED` has these values:

- `Yes` if an SSL connection to the source is permitted
- `No` if an SSL connection to the source is not permitted
- `Ignored` if an SSL connection is permitted but the replica does not have SSL support enabled

[CHANGE MASTER TO](#) options for the other SSL columns: `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_CIPHER`, `MASTER_SSL_CRL`, `MASTER_SSL_CRLPATH`, `MASTER_SSL_KEY`, `MASTER_SSL_VERIFY_SERVER_CERT`.

- `CONNECTION_RETRY_INTERVAL`

The number of seconds between connect retries. ([CHANGE MASTER TO option: MASTER\\_CONNECT\\_RETRY](#))

- `CONNECTION_RETRY_COUNT`

The number of times the replica can attempt to reconnect to the source in the event of a lost connection. ([CHANGE MASTER TO option: MASTER\\_RETRY\\_COUNT](#))

- `HEARTBEAT_INTERVAL`

The replication heartbeat interval on a replica, measured in seconds. ([CHANGE MASTER TO option: MASTER\\_HEARTBEAT\\_PERIOD](#))

- `TLS_VERSION`

The TLS version used on the source. For TLS version information, see [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). ([CHANGE MASTER TO option: MASTER\\_TLS\\_VERSION](#))

This column was added in MySQL 5.7.10.

`TRUNCATE TABLE` is not permitted for the `replication_connection_configuration` table.

The following table shows the correspondence between `replication_connection_configuration` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_connection_configuration</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|----------------------------------------------------------|---------------------------------------|
| <code>CHANNEL_NAME</code>                                | <code>Channel_name</code>             |
| <code>HOST</code>                                        | <code>Master_Host</code>              |
| <code>PORT</code>                                        | <code>Master_Port</code>              |
| <code>USER</code>                                        | <code>Master_User</code>              |
| <code>NETWORK_INTERFACE</code>                           | <code>Master_Bind</code>              |
| <code>AUTO_POSITION</code>                               | <code>Auto_Position</code>            |
| <code>SSL_ALLOWED</code>                                 | <code>Master_SSL_Allowed</code>       |
| <code>SSL_CA_FILE</code>                                 | <code>Master_SSL_CA_File</code>       |
| <code>SSL_CA_PATH</code>                                 | <code>Master_SSL_CA_Path</code>       |

| <code>replication_connection_configuration</code> Column | <code>SHOW SLAVE STATUS</code> Column      |
|----------------------------------------------------------|--------------------------------------------|
| <code>SSL_CERTIFICATE</code>                             | <code>Master_SSL_Cert</code>               |
| <code>SSL_CIPHER</code>                                  | <code>Master_SSL_Cipher</code>             |
| <code>SSL_KEY</code>                                     | <code>Master_SSL_Key</code>                |
| <code>SSL_VERIFY_SERVER_CERTIFICATE</code>               | <code>Master_SSL_Verify_Server_Cert</code> |
| <code>SSL_CRL_FILE</code>                                | <code>Master_SSL_Crl</code>                |
| <code>SSL_CRL_PATH</code>                                | <code>Master_SSL_Crlpath</code>            |
| <code>CONNECTION_RETRY_INTERVAL</code>                   | <code>Connect_Retry</code>                 |
| <code>CONNECTION_RETRY_COUNT</code>                      | <code>Master_Retry_Count</code>            |
| <code>HEARTBEAT_INTERVAL</code>                          | <code>None</code>                          |
| <code>TLS_VERSION</code>                                 | <code>Master_TLS_Version</code>            |

### 25.12.11.2 The `replication_connection_status` Table

This table shows the current status of the replication I/O thread that handles the replica's connection to the source.

Compared to the `replication_connection_configuration` table, `replication_connection_status` changes more frequently. It contains values that change during the connection, whereas `replication_connection_configuration` contains values which define how the replica connects to the source and that remain constant during the connection.

The `replication_connection_status` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 16.2.2, “Replication Channels”](#) for more information.

- `GROUP_NAME`

If this server is a member of a group, shows the name of the group the server belongs to.

- `SOURCE_UUID`

The `server_uuid` value from the source.

- `THREAD_ID`

The I/O thread ID.

- `SERVICE_STATE`

`ON` (thread exists and is active or idle), `OFF` (thread no longer exists), or `CONNECTING` (thread exists and is connecting to the source).

- `RECEIVED_TRANSACTION_SET`

The set of global transaction IDs (GTIDs) corresponding to all transactions received by this replica. Empty if GTIDs are not in use. See [GTID Sets](#) for more information.

- `LAST_ERROR_NUMBER`, `LAST_ERROR_MESSAGE`

The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the replica's error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- `LAST_ERROR_TIMESTAMP`

A timestamp in `YYMMDD hh:mm:ss` format that shows when the most recent I/O error took place.

- `LAST_HEARTBEAT_TIMESTAMP`

A timestamp in `YYMMDD hh:mm:ss` format that shows when the most recent heartbeat signal was received by a replica.

- `COUNT_RECEIVED_HEARTBEATS`

The total number of heartbeat signals that a replica received since the last time it was restarted or reset, or a `CHANGE MASTER TO` statement was issued.

`TRUNCATE TABLE` is not permitted for the `replication_connection_status` table.

The following table shows the correspondence between `replication_connection_status` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_connection_status</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|---------------------------------------------------|---------------------------------------|
| <code>SOURCE_UUID</code>                          | <code>Master_UUID</code>              |
| <code>THREAD_ID</code>                            | <code>None</code>                     |
| <code>SERVICE_STATE</code>                        | <code>Slave_IO_Running</code>         |
| <code>RECEIVED_TRANSACTION_SET</code>             | <code>Retrieved_Gtid_Set</code>       |
| <code>LAST_ERROR_NUMBER</code>                    | <code>Last_IO_Errno</code>            |
| <code>LAST_ERROR_MESSAGE</code>                   | <code>Last_IO_Error</code>            |
| <code>LAST_ERROR_TIMESTAMP</code>                 | <code>Last_IO_Error_Timestamp</code>  |

### 25.12.11.3 The `replication_applier_configuration` Table

This table shows the configuration parameters that affect transactions applied by the replica.

Parameters stored in the table can be changed at runtime with the `CHANGE MASTER TO` statement, as indicated in the column descriptions.

The `replication_applier_configuration` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 16.2.2, “Replication Channels”](#) for more information.

- `DESIRED_DELAY`

The number of seconds that the replica must lag the source. (`CHANGE MASTER TO` option: `MASTER_DELAY`)

`TRUNCATE TABLE` is not permitted for the `replication_applier_configuration` table.

The following table shows the correspondence between `replication_applier_configuration` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_applier_configuration</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|-------------------------------------------------------|---------------------------------------|
| <code>DESIRED_DELAY</code>                            | <code>SQL_Delay</code>                |

#### 25.12.11.4 The replication\_applier\_status Table

This table shows the current general transaction execution status on the replica. The table provides information about general aspects of transaction applier status that are not specific to any thread involved. Thread-specific status information is available in the `replication_applier_status_by_coordinator` table (and `replication_applier_status_by_worker` if the replica is multithreaded).

The `replication_applier_status` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 16.2.2, “Replication Channels”](#) for more information.

- `SERVICE_STATE`

Shows `ON` when the replication channel's applier threads are active or idle, `OFF` means that the applier threads are not active.

- `REMAINING_DELAY`

If the replica is waiting for `DESIRED_DELAY` seconds to pass since the source applied an event, this field contains the number of delay seconds remaining. At other times, this field is `NULL`. (The `DESIRED_DELAY` value is stored in the `replication_applier_configuration` table.)

- `COUNT_TRANSACTIONS_RETRIES`

Shows the number of retries that were made because the replication SQL thread failed to apply a transaction. The maximum number of retries for a given transaction is set by the `slave_transaction_retries` system variable.

`TRUNCATE TABLE` is not permitted for the `replication_applier_status` table.

The following table shows the correspondence between `replication_applier_status` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_applier_status</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|------------------------------------------------|---------------------------------------|
| <code>SERVICE_STATE</code>                     | None                                  |
| <code>REMAINING_DELAY</code>                   | <code>SQL_Remaining_Delay</code>      |

#### 25.12.11.5 The replication\_applier\_status\_by\_coordinator Table

For a multithreaded replica, the replica uses multiple worker threads and a coordinator thread to manage them, and this table shows the status of the coordinator thread. For a single-threaded replica, this table is empty. For a multithreaded replica, the `replication_applier_status_by_worker` table shows the status of the worker threads.

The `replication_applier_status_by_coordinator` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 16.2.2, “Replication Channels”](#) for more information.

- `THREAD_ID`

The SQL/coordinator thread ID.

- `SERVICE_STATE`

`ON` (thread exists and is active or idle) or `OFF` (thread no longer exists).

- `LAST_ERROR_NUMBER, LAST_ERROR_MESSAGE`

The error number and error message of the most recent error that caused the SQL/coordinator thread to stop. An error number of 0 and message which is an empty string means “no error”. If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the replica’s error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

All error codes and messages displayed in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns correspond to error values listed in [Server Error Message Reference](#).

- `LAST_ERROR_TIMESTAMP`

A timestamp in `YYMMDD hh:mm:ss` format that shows when the most recent SQL/coordinator error occurred.

`TRUNCATE TABLE` is not permitted for the `replication_applier_status_by_coordinator` table.

The following table shows the correspondence between `replication_applier_status_by_coordinator` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_applier_status_by_coordinator</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|---------------------------------------------------------------|---------------------------------------|
| <code>THREAD_ID</code>                                        | None                                  |
| <code>SERVICE_STATE</code>                                    | <code>Slave_SQL_Running</code>        |
| <code>LAST_ERROR_NUMBER</code>                                | <code>Last_SQL_Errno</code>           |
| <code>LAST_ERROR_MESSAGE</code>                               | <code>Last_SQL_Error</code>           |
| <code>LAST_ERROR_TIMESTAMP</code>                             | <code>Last_SQL_Error_Timestamp</code> |

### 25.12.11.6 The `replication_applier_status_by_worker` Table

If the replica is not multithreaded, this table shows the status of the applier thread. Otherwise, the replica uses multiple worker threads and a coordinator thread to manage them, and this table shows the status of the worker threads. For a multithreaded replica, the `replication_applier_status_by_coordinator` table shows the status of the coordinator thread.

The `replication_applier_status_by_worker` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 16.2.2, “Replication Channels”](#) for more information.

- `WORKER_ID`

The worker identifier (same value as the `id` column in the `mysql.slave_worker_info` table). After `STOP SLAVE`, the `THREAD_ID` column becomes `NULL`, but the `WORKER_ID` value is preserved.

- `THREAD_ID`

The worker thread identifier.

- `SERVICE_STATE`

`ON` (thread exists and is active or idle) or `OFF` (thread no longer exists).

- `LAST_SEEN_TRANSACTION`

The transaction that the worker has last seen. The worker has not necessarily applied this transaction because it could still be in the process of doing so.

If the `gtid_mode` system variable value is `OFF`, this column is `ANONYMOUS`, indicating that transactions do not have global transaction identifiers (GTIDs) and are identified by file and position only.

If `gtid_mode` is `ON`, the column value is defined as follows:

- If no transaction has executed, the column is empty.
- When a transaction has executed, the column is set from `gtid_next` as soon as `gtid_next` is set. From this moment, the column always shows a GTID.
- The GTID is preserved until the next transaction is executed. If an error occurs, the column value is the GTID of the transaction being executed by the worker when the error occurred. The following statement shows whether or not that transaction has been committed:

```
SELECT GTID_SUBSET(LAST_SEEN_TRANSACTION, @@GLOBAL.GTID_EXECUTED)
FROM performance_schema.replication_applier_status_by_worker;
```

If the statement returns zero, the transaction has not yet been committed, either because it is still being processed, or because the worker thread was stopped while it was being processed. If the statement returns nonzero, the transaction has been committed.

- `LAST_ERROR_NUMBER`, `LAST_ERROR_MESSAGE`

The error number and error message of the most recent error that caused the worker thread to stop. An error number of 0 and message of the empty string mean “no error”. If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the replica’s error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

All error codes and messages displayed in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns correspond to error values listed in [Server Error Message Reference](#).

- `LAST_ERROR_TIMESTAMP`

A timestamp in `YYMMDD hh:mm:ss` format that shows when the most recent worker error occurred.

`TRUNCATE TABLE` is not permitted for the `replication_applier_status_by_worker` table.

The following table shows the correspondence between `replication_applier_status_by_worker` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_applier_status_by_worker</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|----------------------------------------------------------|---------------------------------------|
| <code>WORKER_ID</code>                                   | None                                  |
| <code>THREAD_ID</code>                                   | None                                  |
| <code>SERVICE_STATE</code>                               | None                                  |
| <code>LAST_SEEN_TRANSACTION</code>                       | None                                  |
| <code>LAST_ERROR_NUMBER</code>                           | <code>Last_SQL_Errno</code>           |
| <code>LAST_ERROR_MESSAGE</code>                          | <code>Last_SQL_Error</code>           |
| <code>LAST_ERROR_TIMESTAMP</code>                        | <code>Last_SQL_Error_Timestamp</code> |

### 25.12.11.7 The replication\_group\_members Table

This table shows network and status information for replication group members. The network addresses shown are the addresses used to connect clients to the group, and should not be confused with the member's internal group communication address specified by `group_replication_local_address`.

The `replication_group_members` table has these columns:

- `CHANNEL_NAME`

Name of the Group Replication channel.

- `MEMBER_ID`

Identifier for this member; the same as the server UUID.

- `MEMBER_HOST`

Network address of this member (host name or IP address). Retrieved from the member's `hostname` variable.

- `MEMBER_PORT`

Port on which the server is listening. Retrieved from the member's `port` variable.

- `MEMBER_STATE`

Current state of this member; can be any one of the following:

- `OFFLINE`: The Group Replication plugin is installed but has not been started.
- `RECOVERING`: The server has joined a group from which it is retrieving data.
- `ONLINE`: The member is in a fully functioning state.
- `ERROR`: The member has encountered an error, either during applying transactions or during the recovery phase, and is not participating in the group's transactions.
- `UNREACHABLE`: The failure detection process suspects that this member cannot be contacted, because the group messages have timed out.

`TRUNCATE TABLE` is not permitted for the `replication_group_members` table.

### 25.12.11.8 The replication\_group\_member\_stats Table

This table shows statistical information for MySQL Group Replication members. It is populated only when Group Replication is running.

The `replication_group_member_stats` table has these columns:

- `CHANNEL_NAME`

Name of the Group Replication channel.

- `VIEW_ID`

Current view identifier for this group.

- `MEMBER_ID`

The member server UUID. This has a different value for each member in the group. This also serves as a key because it is unique to each member.

- [COUNT\\_TRANSACTIONS\\_IN\\_QUEUE](#)

The number of transactions in the queue pending conflict detection checks. Once the transactions have been checked for conflicts, if they pass the check, they are queued to be applied as well.

- [COUNT\\_TRANSACTIONS\\_CHECKED](#)

The number of transactions that have been checked for conflicts.

- [COUNT\\_CONFLICTS\\_DETECTED](#)

The number of transactions that have not passed the conflict detection check.

- [COUNT\\_TRANSACTIONS\\_ROWS\\_VALIDATING](#)

Number of transaction rows which can be used for certification, but have not been garbage collected. Can be thought of as the current size of the conflict detection database against which each transaction is certified.

- [TRANSACTIONS\\_COMMITED\\_ALL\\_MEMBERS](#)

The transactions that have been successfully committed on all members of the replication group, shown as [GTID Sets](#). This is updated at a fixed time interval.

- [LAST\\_CONFLICT\\_FREE\\_TRANSACTION](#)

The transaction identifier of the last conflict free transaction which was checked.

`TRUNCATE TABLE` is not permitted for the `replication_group_member_stats` table.

## 25.12.12 Performance Schema Lock Tables

The Performance Schema exposes lock information through these tables:

- [metadata\\_locks](#): Metadata locks held and requested
- [table\\_handles](#): Table locks held and requested

The following sections describe these tables in more detail.

### 25.12.12.1 The `metadata_locks` Table

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency; see [Section 8.11.4, “Metadata Locking”](#). Metadata locking applies not just to tables, but also to schemas, stored programs (procedures, functions, triggers, scheduled events), tablespaces, user locks acquired with the `GET_LOCK()` function (see [Section 12.15, “Locking Functions”](#)), and locks acquired with the locking service described in [Section 5.5.6.1, “The Locking Service”](#).

The Performance Schema exposes metadata lock information through the `metadata_locks` table:

- Locks that have been granted (shows which sessions own which current metadata locks).
- Locks that have been requested but not yet granted (shows which sessions are waiting for which metadata locks).
- Lock requests that have been killed by the deadlock detector.
- Lock requests that have timed out and are waiting for the requesting session's lock request to be discarded.

This information enables you to understand metadata lock dependencies between sessions. You can see not only which lock a session is waiting for, but which session currently holds that lock.

The `metadata_locks` table is read only and cannot be updated. It is autosized by default; to configure the table size, set the `performance_schema_max_metadata_locks` system variable at server startup.

Metadata lock instrumentation uses the `wait/lock/metadata/sql/mdl` instrument, which is disabled by default.

To control metadata lock instrumentation state at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='wait/lock/metadata/sql/mdl=ON'
```

- Disable:

```
[mysqld]
performance-schema-instrument='wait/lock/metadata/sql/mdl=OFF'
```

To control metadata lock instrumentation state at runtime, update the `setup_instruments` table:

- Enable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME = 'wait/lock/metadata/sql/mdl';
```

- Disable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME = 'wait/lock/metadata/sql/mdl';
```

The Performance Schema maintains `metadata_locks` table content as follows, using the `LOCK_STATUS` column to indicate the status of each lock:

- When a metadata lock is requested and obtained immediately, a row with a status of `GRANTED` is inserted.
- When a metadata lock is requested and not obtained immediately, a row with a status of `PENDING` is inserted.
- When a metadata lock previously requested is granted, its row status is updated to `GRANTED`.
- When a metadata lock is released, its row is deleted.
- When a pending lock request is canceled by the deadlock detector to break a deadlock (`ER_LOCK_DEADLOCK`), its row status is updated from `PENDING` to `VICTIM`.
- When a pending lock request times out (`ER_LOCK_WAIT_TIMEOUT`), its row status is updated from `PENDING` to `TIMEOUT`.
- When granted lock or pending lock request is killed, its row status is updated from `GRANTED` or `PENDING` to `KILLED`.
- The `VICTIM`, `TIMEOUT`, and `KILLED` status values are brief and signify that the lock row is about to be deleted.
- The `PRE_ACQUIRE_NOTIFY` and `POST_RELEASE_NOTIFY` status values are brief and signify that the metadata locking subsystem is notifying interested storage engines while entering lock acquisition operations or leaving lock release operations. These status values were added in MySQL 5.7.11.

The `metadata_locks` table has these columns:

- [OBJECT\\_TYPE](#)

The type of lock used in the metadata lock subsystem. The value is one of [GLOBAL](#), [SCHEMA](#), [TABLE](#), [FUNCTION](#), [PROCEDURE](#), [TRIGGER](#) (currently unused), [EVENT](#), [COMMIT](#), [USER LEVEL LOCK](#), [TABLESPACE](#), or [LOCKING SERVICE](#).

A value of [USER LEVEL LOCK](#) indicates a lock acquired with [GET\\_LOCK\(\)](#). A value of [LOCKING SERVICE](#) indicates a lock acquired with the locking service described in [Section 5.5.6.1, “The Locking Service”](#).

- [OBJECT\\_SCHEMA](#)

The schema that contains the object.

- [OBJECT\\_NAME](#)

The name of the instrumented object.

- [OBJECT\\_INSTANCE\\_BEGIN](#)

The address in memory of the instrumented object.

- [LOCK\\_TYPE](#)

The lock type from the metadata lock subsystem. The value is one of [INTENTION\\_EXCLUSIVE](#), [SHARED](#), [SHARED\\_HIGH\\_PRIO](#), [SHARED\\_READ](#), [SHARED\\_WRITE](#), [SHARED\\_UPGRADABLE](#), [SHARED\\_NO\\_WRITE](#), [SHARED\\_NO\\_READ\\_WRITE](#), or [EXCLUSIVE](#).

- [LOCK\\_DURATION](#)

The lock duration from the metadata lock subsystem. The value is one of [STATEMENT](#), [TRANSACTION](#), or [EXPLICIT](#). The [STATEMENT](#) and [TRANSACTION](#) values signify locks that are released implicitly at statement or transaction end, respectively. The [EXPLICIT](#) value signifies locks that survive statement or transaction end and are released by explicit action, such as global locks acquired with [FLUSH TABLES WITH READ LOCK](#).

- [LOCK\\_STATUS](#)

The lock status from the metadata lock subsystem. The value is one of [PENDING](#), [GRANTED](#), [VICTIM](#), [TIMEOUT](#), [KILLED](#), [PRE\\_ACQUIRE\\_NOTIFY](#), or [POST\\_RELEASE\\_NOTIFY](#). The Performance Schema assigns these values as described previously.

- [SOURCE](#)

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- [OWNER\\_THREAD\\_ID](#)

The thread requesting a metadata lock.

- [OWNER\\_EVENT\\_ID](#)

The event requesting a metadata lock.

[TRUNCATE TABLE](#) is not permitted for the [metadata\\_locks](#) table.

### 25.12.12.2 The `table_handles` Table

The Performance Schema exposes table lock information through the [table\\_handles](#) table to show the table locks currently in effect for each opened table handle. [table\\_handles](#) reports what is

recorded by the table lock instrumentation. This information shows which table handles the server has open, how they are locked, and by which sessions.

The `table_handles` table is read only and cannot be updated. It is autosized by default; to configure the table size, set the `performance_schema_max_table_handles` system variable at server startup.

Table lock instrumentation uses the `wait/lock/table/sql/handler` instrument, which is enabled by default.

To control table lock instrumentation state at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='wait/lock/table/sql/handler=ON'
```

- Disable:

```
[mysqld]
performance-schema-instrument='wait/lock/table/sql/handler=OFF'
```

To control table lock instrumentation state at runtime, update the `setup_instruments` table:

- Enable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME = 'wait/lock/table/sql/handler';
```

- Disable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME = 'wait/lock/table/sql/handler';
```

The `table_handles` table has these columns:

- `OBJECT_TYPE`

The table opened by a table handle.

- `OBJECT_SCHEMA`

The schema that contains the object.

- `OBJECT_NAME`

The name of the instrumented object.

- `OBJECT_INSTANCE_BEGIN`

The table handle address in memory.

- `OWNER_THREAD_ID`

The thread owning the table handle.

- `OWNER_EVENT_ID`

The event which caused the table handle to be opened.

- `INTERNAL_LOCK`

The table lock used at the SQL level. The value is one of `READ`, `READ WITH SHARED LOCKS`, `READ HIGH PRIORITY`, `READ NO INSERT`, `WRITE ALLOW WRITE`, `WRITE CONCURRENT INSERT`,

`WRITE LOW PRIORITY`, or `WRITE`. For information about these lock types, see the `include/`  
`thr_lock.h` source file.

- `EXTERNAL_LOCK`

The table lock used at the storage engine level. The value is one of `READ EXTERNAL` or `WRITE EXTERNAL`.

`TRUNCATE TABLE` is not permitted for the `table_handles` table.

## 25.12.13 Performance Schema System Variable Tables

### Note

The value of the `show_compatibility_56` system variable affects the information available from the tables described here. For details, see the description of that variable in [Section 5.1.7, “Server System Variables”](#).

The MySQL server maintains many system variables that indicate how it is configured (see [Section 5.1.7, “Server System Variables”](#)). System variable information is available in these Performance Schema tables:

- `global_variables`: Global system variables. An application that wants only global values should use this table.
- `session_variables`: System variables for the current session. An application that wants all system variable values for its own session should use this table. It includes the session variables for its session, as well as the values of global variables that have no session counterpart.
- `variables_by_thread`: Session system variables for each active session. An application that wants to know the session variable values for specific sessions should use this table. It includes session variables only, identified by thread ID.

The session variable tables (`session_variables`, `variables_by_thread`) contain information only for active sessions, not terminated sessions.

The `global_variables` and `session_variables` tables have these columns:

- `VARIABLE_NAME`  
The system variable name.
- `VARIABLE_VALUE`  
The system variable value. For `global_variables`, this column contains the global value. For `session_variables`, this column contains the variable value in effect for the current session.

The `variables_by_thread` table has these columns:

- `THREAD_ID`  
The thread identifier of the session in which the system variable is defined.
- `VARIABLE_NAME`  
The system variable name.
- `VARIABLE_VALUE`  
The session variable value for the session named by the `THREAD_ID` column.

The `variables_by_thread` table contains system variable information only about foreground threads. If not all threads are instrumented by the Performance Schema, this table may miss some

rows. In this case, the `Performance_schema_thread_instances_lost` status variable is greater than zero.

`TRUNCATE TABLE` is not supported for Performance Schema system variable tables.

## 25.12.14 Performance Schema Status Variable Tables

### Note

The value of the `show_compatibility_56` system variable affects the information available from the tables described here. For details, see the description of that variable in [Section 5.1.7, “Server System Variables”](#).

The MySQL server maintains many status variables that provide information about its operation (see [Section 5.1.9, “Server Status Variables”](#)). Status variable information is available in these Performance Schema tables:

- `global_status`: Global status variables. An application that wants only global values should use this table.
- `session_status`: Status variables for the current session. An application that wants all status variable values for its own session should use this table. It includes the session variables for its session, as well as the values of global variables that have no session counterpart.
- `status_by_thread`: Session status variables for each active session. An application that wants to know the session variable values for specific sessions should use this table. It includes session variables only, identified by thread ID.

There are also summary tables that provide status variable information aggregated by account, host name, and user name. See [Section 25.12.15.10, “Status Variable Summary Tables”](#).

The session variable tables (`session_status`, `status_by_thread`) contain information only for active sessions, not terminated sessions.

The Performance Schema collects statistics for global status variables only for threads for which the `INSTRUMENTED` value is `YES` in the `threads` table. Statistics for session status variables are always collected, regardless of the `INSTRUMENTED` value.

The Performance Schema does not collect statistics for `Com_xxx` status variables in the status variable tables. To obtain global and per-session statement execution counts, use the `events_statements_summary_global_by_event_name` and `events_statements_summary_by_thread_by_event_name` tables, respectively. For example:

```
SELECT EVENT_NAME, COUNT_STAR
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql%';
```

The `global_status` and `session_status` tables have these columns:

- `VARIABLE_NAME`

The status variable name.

- `VARIABLE_VALUE`

The status variable value. For `global_status`, this column contains the global value. For `session_status`, this column contains the variable value for the current session.

The `status_by_thread` table contains the status of each active thread. It has these columns:

- `THREAD_ID`

The thread identifier of the session in which the status variable is defined.

- [VARIABLE\\_NAME](#)

The status variable name.

- [VARIABLE\\_VALUE](#)

The session variable value for the session named by the [THREAD\\_ID](#) column.

The [status\\_by\\_thread](#) table contains status variable information only about foreground threads. If the [performance\\_schema\\_max\\_thread\\_instances](#) system variable is not autoscaled (signified by a value of -1) and the maximum permitted number of instrumented thread objects is not greater than the number of background threads, the table is empty.

The Performance Schema supports [TRUNCATE TABLE](#) for status variable tables as follows:

- [global\\_status](#): Resets thread, account, host, and user status. Resets global status variables except those that the server never resets.
- [session\\_status](#): Not supported.
- [status\\_by\\_thread](#): Aggregates status for all threads to the global status and account status, then resets thread status. If account statistics are not collected, the session status is added to host and user status, if host and user status are collected.

Account, host, and user statistics are not collected if the [performance\\_schema\\_accounts\\_size](#), [performance\\_schema\\_hosts\\_size](#), and [performance\\_schema\\_users\\_size](#) system variables, respectively, are set to 0.

[FLUSH STATUS](#) adds the session status from all active sessions to the global status variables, resets the status of all active sessions, and resets account, host, and user status values aggregated from disconnected sessions.

## 25.12.15 Performance Schema Summary Tables

Summary tables provide aggregated information for terminated events over time. The tables in this group summarize event data in different ways.

Each summary table has grouping columns that determine how to group the data to be aggregated, and summary columns that contain the aggregated values. Tables that summarize events in similar ways often have similar sets of summary columns and differ only in the grouping columns used to determine how events are aggregated.

Summary tables can be truncated with [TRUNCATE TABLE](#). Generally, the effect is to reset the summary columns to 0 or [NULL](#), not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

### Wait Event Summaries

**Table 25.3 Performance Schema Wait Event Summary Tables**

| Name                                          | Description                              |
|-----------------------------------------------|------------------------------------------|
| <a href="#">events_waits_summary_account</a>  | Wait events per account and event name   |
| <a href="#">events_waits_summary_host</a>     | Wait events per host name and event name |
| <a href="#">events_waits_summary_instance</a> | Wait events per instance                 |
| <a href="#">events_waits_summary_thread</a>   | Wait events per thread and event name    |
| <a href="#">events_waits_summary_user</a>     | Wait events per user name and event name |

| Name                                      | Description                |
|-------------------------------------------|----------------------------|
| events_waits_summary_global_by_event_name | Wait events per event name |

## Stage Summaries

**Table 25.4 Performance Schema Stage Event Summary Tables**

| Name                                                  | Description                               |
|-------------------------------------------------------|-------------------------------------------|
| events_stages_summary_global_by_account_by_event_name | Stage events per account and event name   |
| events_stages_summary_global_by_host_by_event_name    | Stage events per host name and event name |
| events_stages_summary_global_by_thread_by_event_name  | Stage waits per thread and event name     |
| events_stages_summary_global_by_user_by_event_name    | Stage events per user name and event name |
| events_stages_summary_per_event_name                  | Stage waits per event name                |

## Statement Summaries

**Table 25.5 Performance Schema Statement Event Summary Tables**

| Name                                                     | Description                                   |
|----------------------------------------------------------|-----------------------------------------------|
| events_statements_summary_global_by_event_name           | Statement events per account and event name   |
| events_statements_summary_global_by_digest               | Statement events per schema and digest value  |
| events_statements_summary_global_by_host_by_event_name   | Statement events per host name and event name |
| events_statements_summary_global_by_program              | Statement events per stored program           |
| events_statements_summary_global_by_thread_by_event_name | Statement events per thread and event name    |
| events_statements_summary_global_by_user_by_event_name   | Statement events per user name and event name |
| events_statements_summary_per_event_name                 | Statement events per event name               |
| prepared_statements_in_use                               | Prepared statement instances and statistics   |

## Transaction Summaries

**Table 25.6 Performance Schema Transaction Event Summary Tables**

| Name                                                        | Description                                     |
|-------------------------------------------------------------|-------------------------------------------------|
| events_transactions_summary_global_by_account_by_event_name | Transaction events per account and event name   |
| events_transactions_summary_global_by_host_by_event_name    | Transaction events per host name and event name |
| events_transactions_summary_global_by_thread_by_event_name  | Transaction events per thread and event name    |
| events_transactions_summary_global_by_user_by_event_name    | Transaction events per user name and event name |
| events_transactions_summary_per_event_name                  | Transaction events per event name               |

## Object Wait Summaries

**Table 25.7 Performance Schema Object Event Summary Tables**

| Name                   | Description      |
|------------------------|------------------|
| objects_summary_global | Object summaries |

## File I/O Summaries

**Table 25.8 Performance Schema File I/O Event Summary Tables**

| Name                  | Description                |
|-----------------------|----------------------------|
| file_summary_by_event | File events per event name |

| Name                                  | Description                   |
|---------------------------------------|-------------------------------|
| <code>file_summary_by_instance</code> | File events per file instance |

## Table I/O and Lock Wait Summaries

**Table 25.9 Performance Schema Table I/O and Lock Wait Event Summary Tables**

| Name                                           | Description                |
|------------------------------------------------|----------------------------|
| <code>table_io_waits_summary_by_index</code>   | Table I/O waits per index  |
| <code>table_io_waits_summary_by_table</code>   | Table I/O waits per table  |
| <code>table_lock_waits_summary_by_table</code> | Table lock waits per table |

## Socket Summaries

**Table 25.10 Performance Schema Socket Event Summary Tables**

| Name                                      | Description                         |
|-------------------------------------------|-------------------------------------|
| <code>socket_summary_by_event_name</code> | Socket waits and I/O per event name |
| <code>socket_summary_by_instance</code>   | Socket waits and I/O per instance   |

## Memory Summaries

**Table 25.11 Performance Schema Memory Operation Summary Tables**

| Name                                   | Description                                  |
|----------------------------------------|----------------------------------------------|
| <code>memory_summary_by_account</code> | Memory operations per account and event name |
| <code>memory_summary_by_host</code>    | Memory operations per host and event name    |
| <code>memory_summary_by_thread</code>  | Memory operations per thread and event name  |
| <code>memory_summary_by_user</code>    | Memory operations per user and event name    |
| <code>memory_summary_global</code>     | Memory operations globally per event name    |

## Status Variable Summaries

**Table 25.12 Performance Schema Error Status Variable Summary Tables**

| Name                           | Description                            |
|--------------------------------|----------------------------------------|
| <code>status_by_account</code> | Session status variables per account   |
| <code>status_by_host</code>    | Session status variables per host name |
| <code>status_by_user</code>    | Session status variables per user name |

### 25.12.15.1 Wait Event Summary Tables

The Performance Schema maintains tables for collecting current and recent wait events, and aggregates that information in summary tables. [Section 25.12.4, “Performance Schema Wait Event Tables”](#) describes the events on which wait summaries are based. See that discussion for information about the content of wait events, the current and recent wait event tables, and how to control wait event collection, which is disabled by default.

Example wait event summary information:

```
mysql> SELECT *
 FROM performance_schema.events_waits_summary_global_by_event_name\G
...
***** 6. row *****
EVENT_NAME: wait/synch/mutex/sql/BINARY_LOG::LOCK_index
```

```

COUNT_STAR: 8
SUM_TIMER_WAIT: 2119302
MIN_TIMER_WAIT: 196092
AVG_TIMER_WAIT: 264912
MAX_TIMER_WAIT: 569421
...
***** 9. row *****
EVENT_NAME: wait/synch/mutex/sql/hash_filo::lock
COUNT_STAR: 69
SUM_TIMER_WAIT: 16848828
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 244185
MAX_TIMER_WAIT: 735345
...

```

Each wait event summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `events_waits_summary_by_account_by_event_name` has `EVENT_NAME`, `USER`, and `HOST` columns. Each row summarizes events for a given account (user and host combination) and event name.
- `events_waits_summary_by_host_by_event_name` has `EVENT_NAME` and `HOST` columns. Each row summarizes events for a given host and event name.
- `events_waits_summary_by_instance` has `EVENT_NAME` and `OBJECT_INSTANCE_BEGIN` columns. Each row summarizes events for a given event name and object. If an instrument is used to create multiple instances, each instance has a unique `OBJECT_INSTANCE_BEGIN` value and is summarized separately in this table.
- `events_waits_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.
- `events_waits_summary_by_user_by_event_name` has `EVENT_NAME` and `USER` columns. Each row summarizes events for a given user and event name.
- `events_waits_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name. An instrument might be used to create multiple instances of the instrumented object. For example, if there is an instrument for a mutex that is created for each connection, there are as many instances as there are connections. The summary row for the instrument summarizes over all these instances.

Each wait event summary table has these summary columns containing aggregated values:

- `COUNT_STAR`  
The number of summarized events. This value includes all events, whether timed or nontimed.
- `SUM_TIMER_WAIT`  
The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of `NULL`. The same is true for the other `xxx_TIMER_WAIT` values.
- `MIN_TIMER_WAIT`  
The minimum wait time of the summarized timed events.
- `AVG_TIMER_WAIT`  
The average wait time of the summarized timed events.
- `MAX_TIMER_WAIT`

The maximum wait time of the summarized timed events.

`TRUNCATE TABLE` is permitted for wait summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.
- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each wait summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_waits_summary_global_by_event_name`. For details, see [Section 25.12.8, “Performance Schema Connection Tables”](#).

### 25.12.15.2 Stage Summary Tables

The Performance Schema maintains tables for collecting current and recent stage events, and aggregates that information in summary tables. [Section 25.12.5, “Performance Schema Stage Event Tables”](#) describes the events on which stage summaries are based. See that discussion for information about the content of stage events, the current and historical stage event tables, and how to control stage event collection, which is disabled by default.

Example stage event summary information:

```
mysql> SELECT *
 FROM performance_schema.events_stages_summary_global_by_event_name\G
...
***** 5. row *****
EVENT_NAME: stage/sql/checking permissions
COUNT_STAR: 57
SUM_TIMER_WAIT: 26501888880
MIN_TIMER_WAIT: 7317456
AVG_TIMER_WAIT: 464945295
MAX_TIMER_WAIT: 12858936792
...
***** 9. row *****
EVENT_NAME: stage/sql/closing tables
COUNT_STAR: 37
SUM_TIMER_WAIT: 662606568
MIN_TIMER_WAIT: 1593864
AVG_TIMER_WAIT: 17907891
MAX_TIMER_WAIT: 437977248
...
```

Each stage summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `events_stages_summary_by_account_by_event_name` has `EVENT_NAME`, `USER`, and `HOST` columns. Each row summarizes events for a given account (user and host combination) and event name.
- `events_stages_summary_by_host_by_event_name` has `EVENT_NAME` and `HOST` columns. Each row summarizes events for a given host and event name.
- `events_stages_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.
- `events_stages_summary_by_user_by_event_name` has `EVENT_NAME` and `USER` columns. Each row summarizes events for a given user and event name.
- `events_stages_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.

Each stage summary table has these summary columns containing aggregated values: `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, and `MAX_TIMER_WAIT`. These columns are analogous to the columns of the same names in the wait event summary tables (see [Section 25.12.15.1, “Wait Event Summary Tables”](#)), except that the stage summary tables aggregate events from `events_stages_current` rather than `events_waits_current`.

`TRUNCATE TABLE` is permitted for stage summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.
- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each stage summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_stages_summary_global_by_event_name`. For details, see [Section 25.12.8, “Performance Schema Connection Tables”](#).

### 25.12.15.3 Statement Summary Tables

The Performance Schema maintains tables for collecting current and recent statement events, and aggregates that information in summary tables. [Section 25.12.6, “Performance Schema Statement Event Tables”](#) describes the events on which statement summaries are based. See that discussion for information about the content of statement events, the current and historical statement event tables, and how to control statement event collection, which is partially disabled by default.

Example statement event summary information:

```
mysql> SELECT *
 FROM performance_schema.events_statements_summary_global_by_event_name\G
***** 1. row *****
 EVENT_NAME: statement/sql/select
 COUNT_STAR: 25
 SUM_TIMER_WAIT: 1535983999000
 MIN_TIMER_WAIT: 209823000
 AVG_TIMER_WAIT: 61439359000
 MAX_TIMER_WAIT: 1363397650000
 SUM_LOCK_TIME: 20186000000
 SUM_ERRORS: 0
 SUM_WARNINGS: 0
 SUM_ROWS_AFFECTED: 0
 SUM_ROWS_SENT: 388
 SUM_ROWS_EXAMINED: 370
 SUM_CREATED_TMP_DISK_TABLES: 0
 SUM_CREATED_TMP_TABLES: 0
 SUM_SELECT_FULL_JOIN: 0
 SUM_SELECT_FULL_RANGE_JOIN: 0
 SUM_SELECT_RANGE: 0
 SUM_SELECT_RANGE_CHECK: 0
 SUM_SELECT_SCAN: 6
 SUM_SORT_MERGE_PASSES: 0
 SUM_SORT_RANGE: 0
 SUM_SORT_ROWS: 0
 SUM_SORT_SCAN: 0
 SUM_NO_INDEX_USED: 6
 SUM_NO_GOOD_INDEX_USED: 0
...

```

Each statement summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `events_statements_summary_by_account_by_event_name` has `EVENT_NAME`, `USER`, and `HOST` columns. Each row summarizes events for a given account (user and host combination) and event name.

- `events_statements_summary_by_digest` has `SCHEMA_NAME` and `DIGEST` columns. Each row summarizes events per schema and digest value. (The `DIGEST_TEXT` column contains the corresponding normalized statement digest text, but is neither a grouping nor a summary column.)  
The maximum number of rows in the table is autosized at server startup. To set this maximum explicitly, set the `performance_schema_digests_size` system variable at server startup.
- `events_statements_summary_by_host_by_event_name` has `EVENT_NAME` and `HOST` columns. Each row summarizes events for a given host and event name.
- `events_statements_summary_by_program` has `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME` columns. Each row summarizes events for a given stored program (stored procedure or function, trigger, or event).
- `events_statements_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.
- `events_statements_summary_by_user_by_event_name` has `EVENT_NAME` and `USER` columns. Each row summarizes events for a given user and event name.
- `events_statements_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.
- `prepared_statements_instances` has an `OBJECT_INSTANCE_BEGIN` column. Each row summarizes events for a given prepared statement.

Each statement summary table has these summary columns containing aggregated values (with exceptions as noted):

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`  
These columns are analogous to the columns of the same names in the wait event summary tables (see [Section 25.12.15.1, “Wait Event Summary Tables”](#)), except that the statement summary tables aggregate events from `events_statements_current` rather than `events_waits_current`.  
The `prepared_statements_instances` table does not have these columns.
- `SUM_xxx`  
The aggregate of the corresponding `xxx` column in the `events_statements_current` table. For example, the `SUM_LOCK_TIME` and `SUM_ERRORS` columns in statement summary tables are the aggregates of the `LOCK_TIME` and `ERRORS` columns in `events_statements_current` table.

The `events_statements_summary_by_digest` table has these additional summary columns:

- `FIRST_SEEN`, `LAST_SEEN`  
Timestamps indicating when statements with the given digest value were first seen and most recently seen.

The `events_statements_summary_by_program` table has these additional summary columns:

- `COUNT_STATEMENTS`, `SUM_STATEMENTS_WAIT`, `MIN_STATEMENTS_WAIT`,  
`AVG_STATEMENTS_WAIT`, `MAX_STATEMENTS_WAIT`  
Statistics about nested statements invoked during stored program execution.

The `prepared_statements_instances` table has these additional summary columns:

- `COUNT_EXECUTE`, `SUM_TIMER_EXECUTE`, `MIN_TIMER_EXECUTE`, `AVG_TIMER_EXECUTE`,  
`MAX_TIMER_EXECUTE`  
Aggregated statistics for executions of the prepared statement.

`TRUNCATE TABLE` is permitted for statement summary tables. It has these effects:

- For `events_statements_summary_by_digest`, it removes the rows.
- For other summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.
- For other summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each statement summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_statements_summary_global_by_event_name`. For details, see [Section 25.12.8, “Performance Schema Connection Tables”](#).

## Statement Digest Aggregation Rules

If the `statements_digest` consumer is enabled, aggregation into `events_statements_summary_by_digest` occurs as follows when a statement completes. Aggregation is based on the `DIGEST` value computed for the statement.

- If a `events_statements_summary_by_digest` row already exists with the digest value for the statement that just completed, statistics for the statement are aggregated to that row. The `LAST_SEEN` column is updated to the current time.
- If no row has the digest value for the statement that just completed, and the table is not full, a new row is created for the statement. The `FIRST_SEEN` and `LAST_SEEN` columns are initialized with the current time.
- If no row has the statement digest value for the statement that just completed, and the table is full, the statistics for the statement that just completed are added to a special “catch-all” row with `DIGEST = NULL`, which is created if necessary. If the row is created, the `FIRST_SEEN` and `LAST_SEEN` columns are initialized with the current time. Otherwise, the `LAST_SEEN` column is updated with the current time.

The row with `DIGEST = NULL` is maintained because Performance Schema tables have a maximum size due to memory constraints. The `DIGEST = NULL` row permits digests that do not match other rows to be counted even if the summary table is full, using a common “other” bucket. This row helps you estimate whether the digest summary is representative:

- A `DIGEST = NULL` row that has a `COUNT_STAR` value that represents 5% of all digests shows that the digest summary table is very representative; the other rows cover 95% of the statements seen.
- A `DIGEST = NULL` row that has a `COUNT_STAR` value that represents 50% of all digests shows that the digest summary table is not very representative; the other rows cover only half the statements seen. Most likely the DBA should increase the maximum table size so that more of the rows counted in the `DIGEST = NULL` row would be counted using more specific rows instead. By default, the table is autosized, but if this size is too small, set the `performance_schema_digests_size` system variable to a larger value at server startup.

## Stored Program Instrumentation Behavior

For stored program types for which instrumentation is enabled in the `setup_objects` table, `events_statements_summary_by_program` maintains statistics for stored programs as follows:

- A row is added for an object when it is first used in the server.
- The row for an object is removed when the object is dropped.
- Statistics are aggregated in the row for an object as it executes.

See also [Section 25.4.3, “Event Pre-Filtering”](#).

#### 25.12.15.4 Transaction Summary Tables

The Performance Schema maintains tables for collecting current and recent transaction events, and aggregates that information in summary tables. [Section 25.12.7, “Performance Schema Transaction Tables”](#) describes the events on which transaction summaries are based. See that discussion for information about the content of transaction events, the current and historical transaction event tables, and how to control transaction event collection, which is disabled by default.

Example transaction event summary information:

```
mysql> SELECT *
 FROM performance_schema.events_transactions_summary_global_by_event_name
 LIMIT 1\G

 1. row ****
EVENT_NAME: transaction
COUNT_STAR: 5
SUM_TIMER_WAIT: 19550092000
MIN_TIMER_WAIT: 2954148000
AVG_TIMER_WAIT: 3910018000
MAX_TIMER_WAIT: 5486275000
COUNT_READ_WRITE: 5
SUM_TIMER_READ_WRITE: 19550092000
MIN_TIMER_READ_WRITE: 2954148000
AVG_TIMER_READ_WRITE: 3910018000
MAX_TIMER_READ_WRITE: 5486275000
COUNT_READ_ONLY: 0
SUM_TIMER_READ_ONLY: 0
MIN_TIMER_READ_ONLY: 0
AVG_TIMER_READ_ONLY: 0
MAX_TIMER_READ_ONLY: 0
```

Each transaction summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `events_transactions_summary_by_account_by_event_name` has `USER`, `HOST`, and `EVENT_NAME` columns. Each row summarizes events for a given account (user and host combination) and event name.
- `events_transactions_summary_by_host_by_event_name` has `HOST` and `EVENT_NAME` columns. Each row summarizes events for a given host and event name.
- `events_transactions_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.
- `events_transactions_summary_by_user_by_event_name` has `USER` and `EVENT_NAME` columns. Each row summarizes events for a given user and event name.
- `events_transactions_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.

Each transaction summary table has these summary columns containing aggregated values:

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns are analogous to the columns of the same names in the wait event summary tables (see [Section 25.12.15.1, “Wait Event Summary Tables”](#)), except that the transaction summary tables aggregate events from `events_transactions_current` rather than `events_waits_current`. These columns summarize read-write and read-only transactions.

- `COUNT_READ_WRITE`, `SUM_TIMER_READ_WRITE`, `MIN_TIMER_READ_WRITE`, `AVG_TIMER_READ_WRITE`, `MAX_TIMER_READ_WRITE`

These are similar to the `COUNT_STAR` and `xxx_TIMER_WAIT` columns, but summarize read-write transactions only. The transaction access mode specifies whether transactions operate in read/write or read-only mode.

- `COUNT_READ_ONLY`, `SUM_TIMER_READ_ONLY`, `MIN_TIMER_READ_ONLY`,  
`AVG_TIMER_READ_ONLY`, `MAX_TIMER_READ_ONLY`

These are similar to the `COUNT_STAR` and `xxx_TIMER_WAIT` columns, but summarize read-only transactions only. The transaction access mode specifies whether transactions operate in read/write or read-only mode.

`TRUNCATE TABLE` is permitted for transaction summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.
- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each transaction summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_transactions_summary_global_by_event_name`. For details, see [Section 25.12.8, “Performance Schema Connection Tables”](#).

## Transaction Aggregation Rules

Transaction event collection occurs without regard to isolation level, access mode, or autocommit mode.

Transaction event collection occurs for all non-aborted transactions initiated by the server, including empty transactions.

Read-write transactions are generally more resource intensive than read-only transactions, therefore transaction summary tables include separate aggregate columns for read-write and read-only transactions.

Resource requirements may also vary with transaction isolation level. However, presuming that only one isolation level would be used per server, aggregation by isolation level is not provided.

### 25.12.15.5 Object Wait Summary Table

The Performance Schema maintains the `objects_summary_global_by_type` table for aggregating object wait events.

Example object wait event summary information:

```
mysql> SELECT * FROM performance_schema.objects_summary_global_by_type\G
...
***** 3. row *****
 OBJECT_TYPE: TABLE
 OBJECT_SCHEMA: test
 OBJECT_NAME: t
 COUNT_STAR: 3
 SUM_TIMER_WAIT: 263126976
 MIN_TIMER_WAIT: 1522272
 AVG_TIMER_WAIT: 87708678
 MAX_TIMER_WAIT: 258428280
 ...
***** 10. row *****
 OBJECT_TYPE: TABLE
 OBJECT_SCHEMA: mysql
 OBJECT_NAME: user
 COUNT_STAR: 14
 SUM_TIMER_WAIT: 365567592
```

```
MIN_TIMER_WAIT: 1141704
AVG_TIMER_WAIT: 26111769
MAX_TIMER_WAIT: 334783032
...
```

The `objects_summary_global_by_type` table has these grouping columns to indicate how the table aggregates events: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. Each row summarizes events for the given object.

`objects_summary_global_by_type` has the same summary columns as the `events_waits_summary_by_xxx` tables. See [Section 25.12.15.1, “Wait Event Summary Tables”](#).

`TRUNCATE TABLE` is permitted for the object summary table. It resets the summary columns to zero rather than removing rows.

## 25.12.15.6 File I/O Summary Tables

The Performance Schema maintains file I/O summary tables that aggregate information about I/O operations.

Example file I/O event summary information:

```
mysql> SELECT * FROM performance_schema.file_summary_by_event_name\G
...
***** 2. row *****
EVENT_NAME: wait/io/file/sql/binlog
COUNT_STAR: 31
SUM_TIMER_WAIT: 8243784888
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 265928484
MAX_TIMER_WAIT: 6490658832
...
mysql> SELECT * FROM performance_schema.file_summary_by_instance\G
...
***** 2. row *****
FILE_NAME: /var/mysql/share/english/errmsg.sys
EVENT_NAME: wait/io/file/sql/ERRMSG
EVENT_NAME: wait/io/file/sql/ERRMSG
OBJECT_INSTANCE_BEGIN: 4686193384
COUNT_STAR: 5
SUM_TIMER_WAIT: 13990154448
MIN_TIMER_WAIT: 26349624
AVG_TIMER_WAIT: 2798030607
MAX_TIMER_WAIT: 8150662536
...
```

Each file I/O summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `file_summary_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.
- `file_summary_by_instance` has `FILE_NAME`, `EVENT_NAME`, and `OBJECT_INSTANCE_BEGIN` columns. Each row summarizes events for a given file and event name.

Each file I/O summary table has the following summary columns containing aggregated values. Some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all I/O operations.

- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`, `SUM_NUMBER_OF_BYTES_READ`

These columns aggregate all read operations, including `FGETS`, `FGETC`, `FREAD`, and `READ`.

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`,  
`MAX_TIMER_WRITE`, `SUM_NUMBER_OF_BYTES_WRITE`

These columns aggregate all write operations, including `FPUTS`, `FPUTC`, `FPRINTF`, `VPRINTF`,  
`FWRITE`, and `PWRITE`.

- `COUNT_MISC`, `SUM_TIMER_MISC`, `MIN_TIMER_MISC`, `AVG_TIMER_MISC`, `MAX_TIMER_MISC`

These columns aggregate all other I/O operations, including `CREATE`, `DELETE`, `OPEN`, `CLOSE`,  
`STREAM_OPEN`, `STREAM_CLOSE`, `SEEK`, `TELL`, `FLUSH`, `STAT`, `FSTAT`, `CHSIZE`, `RENAME`, and `SYNC`.  
There are no byte counts for these operations.

`TRUNCATE TABLE` is permitted for file I/O summary tables. It resets the summary columns to zero rather than removing rows.

The MySQL server uses several techniques to avoid I/O operations by caching information read from files, so it is possible that statements you might expect to result in I/O events do not do so. You may be able to ensure that I/O does occur by flushing caches or restarting the server to reset its state.

## 25.12.15.7 Table I/O and Lock Wait Summary Tables

The following sections describe the table I/O and lock wait summary tables:

- `table_io_waits_summary_by_index_usage`: Table I/O waits per index
- `table_io_waits_summary_by_table`: Table I/O waits per table
- `table_lock_waits_summary_by_table`: Table lock waits per table

### The `table_io_waits_summary_by_table` Table

The `table_io_waits_summary_by_table` table aggregates all table I/O wait events, as generated by the `wait/io/table/sql/handler` instrument. The grouping is by table.

The `table_io_waits_summary_by_table` table has these grouping columns to indicate how the table aggregates events: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. These columns have the same meaning as in the `events_waits_current` table. They identify the table to which the row applies.

`table_io_waits_summary_by_table` has the following summary columns containing aggregated values. As indicated in the column descriptions, some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. For example, columns that aggregate all writes hold the sum of the corresponding columns that aggregate inserts, updates, and deletes. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all I/O operations. They are the same as the sum of the corresponding `xxx_READ` and `xxx_WRITE` columns.

- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`

These columns aggregate all read operations. They are the same as the sum of the corresponding `xxx_FETCH` columns.

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`,  
`MAX_TIMER_WRITE`

These columns aggregate all write operations. They are the same as the sum of the corresponding `xxx_INSERT`, `xxx_UPDATE`, and `xxx_DELETE` columns.

- `COUNT_FETCH`, `SUM_TIMER_FETCH`, `MIN_TIMER_FETCH`, `AVG_TIMER_FETCH`, `MAX_TIMER_FETCH`

These columns aggregate all fetch operations.

- `COUNT_INSERT`, `SUM_TIMER_INSERT`, `MIN_TIMER_INSERT`, `AVG_TIMER_INSERT`, `MAX_TIMER_INSERT`

These columns aggregate all insert operations.

- `COUNT_UPDATE`, `SUM_TIMER_UPDATE`, `MIN_TIMER_UPDATE`, `AVG_TIMER_UPDATE`, `MAX_TIMER_UPDATE`

These columns aggregate all update operations.

- `COUNT_DELETE`, `SUM_TIMER_DELETE`, `MIN_TIMER_DELETE`, `AVG_TIMER_DELETE`, `MAX_TIMER_DELETE`

These columns aggregate all delete operations.

`TRUNCATE TABLE` is permitted for table I/O summary tables. It resets the summary columns to zero rather than removing rows. Truncating this table also truncates the `table_io_waits_summary_by_index_usage` table.

## The `table_io_waits_summary_by_index_usage` Table

The `table_io_waits_summary_by_index_usage` table aggregates all table index I/O wait events, as generated by the `wait/io/table/sql/handler` instrument. The grouping is by table index.

The columns of `table_io_waits_summary_by_index_usage` are nearly identical to `table_io_waits_summary_by_table`. The only difference is the additional group column, `INDEX_NAME`, which corresponds to the name of the index that was used when the table I/O wait event was recorded:

- A value of `PRIMARY` indicates that table I/O used the primary index.
- A value of `NULL` means that table I/O used no index.
- Inserts are counted against `INDEX_NAME = NULL`.

`TRUNCATE TABLE` is permitted for table I/O summary tables. It resets the summary columns to zero rather than removing rows. This table is also truncated by truncation of the `table_io_waits_summary_by_table` table. A DDL operation that changes the index structure of a table may cause the per-index statistics to be reset.

## The `table_lock_waits_summary_by_table` Table

The `table_lock_waits_summary_by_table` table aggregates all table lock wait events, as generated by the `wait/lock/table/sql/handler` instrument. The grouping is by table.

This table contains information about internal and external locks:

- An internal lock corresponds to a lock in the SQL layer. This is currently implemented by a call to `thr_lock()`. In event rows, these locks are distinguished by the `OPERATION` column, which has one of these values:

```
read normal
read with shared locks
read high priority
```

```
read no insert
write allow write
write concurrent insert
write delayed
write low priority
write normal
```

- An external lock corresponds to a lock in the storage engine layer. This is currently implemented by a call to `handler::external_lock()`. In event rows, these locks are distinguished by the `OPERATION` column, which has one of these values:

```
read external
write external
```

The `table_lock_waits_summary_by_table` table has these grouping columns to indicate how the table aggregates events: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. These columns have the same meaning as in the `events_waits_current` table. They identify the table to which the row applies.

`table_lock_waits_summary_by_table` has the following summary columns containing aggregated values. As indicated in the column descriptions, some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. For example, columns that aggregate all locks hold the sum of the corresponding columns that aggregate read and write locks. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR, SUM_TIMER_WAIT, MIN_TIMER_WAIT, AVG_TIMER_WAIT, MAX_TIMER_WAIT`

These columns aggregate all lock operations. They are the same as the sum of the corresponding `xxx_READ` and `xxx_WRITE` columns.

- `COUNT_READ, SUM_TIMER_READ, MIN_TIMER_READ, AVG_TIMER_READ, MAX_TIMER_READ`

These columns aggregate all read-lock operations. They are the same as the sum of the corresponding `xxx_READ_NORMAL`, `xxx_READ_WITH_SHARED_LOCKS`, `xxx_READ_HIGH_PRIORITY`, and `xxx_READ_NO_INSERT` columns.

- `COUNT_WRITE, SUM_TIMER_WRITE, MIN_TIMER_WRITE, AVG_TIMER_WRITE, MAX_TIMER_WRITE`

These columns aggregate all write-lock operations. They are the same as the sum of the corresponding `xxx_WRITE_ALLOW_WRITE`, `xxx_WRITE_CONCURRENT_INSERT`, `xxx_WRITE_LOW_PRIORITY`, and `xxx_WRITE_NORMAL` columns.

- `COUNT_READ_NORMAL, SUM_TIMER_READ_NORMAL, MIN_TIMER_READ_NORMAL, AVG_TIMER_READ_NORMAL, MAX_TIMER_READ_NORMAL`

These columns aggregate internal read locks.

- `COUNT_READ_WITH_SHARED_LOCKS, SUM_TIMER_READ_WITH_SHARED_LOCKS, MIN_TIMER_READ_WITH_SHARED_LOCKS, AVG_TIMER_READ_WITH_SHARED_LOCKS, MAX_TIMER_READ_WITH_SHARED_LOCKS`

These columns aggregate internal read locks.

- `COUNT_READ_HIGH_PRIORITY, SUM_TIMER_READ_HIGH_PRIORITY, MIN_TIMER_READ_HIGH_PRIORITY, AVG_TIMER_READ_HIGH_PRIORITY, MAX_TIMER_READ_HIGH_PRIORITY`

These columns aggregate internal read locks.

- `COUNT_READ_NO_INSERT, SUM_TIMER_READ_NO_INSERT, MIN_TIMER_READ_NO_INSERT, AVG_TIMER_READ_NO_INSERT, MAX_TIMER_READ_NO_INSERT`

These columns aggregate internal read locks.

- `COUNT_READ_EXTERNAL`, `SUM_TIMER_READ_EXTERNAL`, `MIN_TIMER_READ_EXTERNAL`,  
`AVG_TIMER_READ_EXTERNAL`, `MAX_TIMER_READ_EXTERNAL`

These columns aggregate external read locks.

- `COUNT_WRITE_ALLOW_WRITE`, `SUM_TIMER_WRITE_ALLOW_WRITE`,  
`MIN_TIMER_WRITE_ALLOW_WRITE`, `AVG_TIMER_WRITE_ALLOW_WRITE`,  
`MAX_TIMER_WRITE_ALLOW_WRITE`

These columns aggregate internal write locks.

- `COUNT_WRITE_CONCURRENT_INSERT`, `SUM_TIMER_WRITE_CONCURRENT_INSERT`,  
`MIN_TIMER_WRITE_CONCURRENT_INSERT`, `AVG_TIMER_WRITE_CONCURRENT_INSERT`,  
`MAX_TIMER_WRITE_CONCURRENT_INSERT`

These columns aggregate internal write locks.

- `COUNT_WRITE_LOW_PRIORITY`, `SUM_TIMER_WRITE_LOW_PRIORITY`,  
`MIN_TIMER_WRITE_LOW_PRIORITY`, `AVG_TIMER_WRITE_LOW_PRIORITY`,  
`MAX_TIMER_WRITE_LOW_PRIORITY`

These columns aggregate internal write locks.

- `COUNT_WRITE_NORMAL`, `SUM_TIMER_WRITE_NORMAL`, `MIN_TIMER_WRITE_NORMAL`,  
`AVG_TIMER_WRITE_NORMAL`, `MAX_TIMER_WRITE_NORMAL`

These columns aggregate internal write locks.

- `COUNT_WRITE_EXTERNAL`, `SUM_TIMER_WRITE_EXTERNAL`, `MIN_TIMER_WRITE_EXTERNAL`,  
`AVG_TIMER_WRITE_EXTERNAL`, `MAX_TIMER_WRITE_EXTERNAL`

These columns aggregate external write locks.

`TRUNCATE TABLE` is permitted for table lock summary tables. It resets the summary columns to zero rather than removing rows.

### 25.12.15.8 Socket Summary Tables

These socket summary tables aggregate timer and byte count information for socket operations:

- `socket_summary_by_event_name`: Aggregate timer and byte count statistics generated by the `wait/io/socket/*` instruments for all socket I/O operations, per socket instrument.
- `socket_summary_by_instance`: Aggregate timer and byte count statistics generated by the `wait/io/socket/*` instruments for all socket I/O operations, per socket instance. When a connection terminates, the row in `socket_summary_by_instance` corresponding to it is deleted.

The socket summary tables do not aggregate waits generated by `idle` events while sockets are waiting for the next request from the client. For `idle` event aggregations, use the wait-event summary tables; see [Section 25.12.15.1, “Wait Event Summary Tables”](#).

Each socket summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `socket_summary_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.
- `socket_summary_by_instance` has an `OBJECT_INSTANCE_BEGIN` column. Each row summarizes events for a given object.

Each socket summary table has these summary columns containing aggregated values:

- `COUNT_STAR, SUM_TIMER_WAIT, MIN_TIMER_WAIT, AVG_TIMER_WAIT, MAX_TIMER_WAIT`

These columns aggregate all operations.

- `COUNT_READ, SUM_TIMER_READ, MIN_TIMER_READ, AVG_TIMER_READ, MAX_TIMER_READ, SUM_NUMBER_OF_BYTES_READ`

These columns aggregate all receive operations (`RECV`, `RECVFROM`, and `RECVMSG`).

- `COUNT_WRITE, SUM_TIMER_WRITE, MIN_TIMER_WRITE, AVG_TIMER_WRITE, MAX_TIMER_WRITE, SUM_NUMBER_OF_BYTES_WRITE`

These columns aggregate all send operations (`SEND`, `SENDTO`, and `SENDMSG`).

- `COUNT_MISC, SUM_TIMER_MISC, MIN_TIMER_MISC, AVG_TIMER_MISC, MAX_TIMER_MISC`

These columns aggregate all other socket operations, such as `CONNECT`, `LISTEN`, `ACCEPT`, `CLOSE`, and `SHUTDOWN`. There are no byte counts for these operations.

The `socket_summary_by_instance` table also has an `EVENT_NAME` column that indicates the class of the socket: `client_connection`, `server_tcpip_socket`, `server_unix_socket`. This column can be grouped on to isolate, for example, client activity from that of the server listening sockets.

`TRUNCATE TABLE` is permitted for socket summary tables. Except for `events_statements_summary_by_digest`, it resets the summary columns to zero rather than removing rows.

## 25.12.15.9 Memory Summary Tables

The Performance Schema instruments memory usage and aggregates memory usage statistics, detailed by these factors:

- Type of memory used (various caches, internal buffers, and so forth)
- Thread, account, user, host indirectly performing the memory operation

The Performance Schema instruments the following aspects of memory use

- Memory sizes used
- Operation counts
- Low and high water marks

Memory sizes help to understand or tune the memory consumption of the server.

Operation counts help to understand or tune the overall pressure the server is putting on the memory allocator, which has an impact on performance. Allocating a single byte one million times is not the same as allocating one million bytes a single time; tracking both sizes and counts can expose the difference.

Low and high water marks are critical to detect workload spikes, overall workload stability, and possible memory leaks.

Memory summary tables do not contain timing information because memory events are not timed.

For information about collecting memory usage data, see [Memory Instrumentation Behavior](#).

Example memory event summary information:

```
mysql> SELECT *
```

```

FROM performance_schema.memory_summary_global_by_event_name
WHERE EVENT_NAME = 'memory/sql/TABLE'\G

***** 1. row *****
EVENT_NAME: memory/sql/TABLE
COUNT_ALLOC: 1381
COUNT_FREE: 924
SUM_NUMBER_OF_BYTES_ALLOC: 2059873
SUM_NUMBER_OF_BYTES_FREE: 1407432
LOW_COUNT_USED: 0
CURRENT_COUNT_USED: 457
HIGH_COUNT_USED: 461
LOW_NUMBER_OF_BYTES_USED: 0
CURRENT_NUMBER_OF_BYTES_USED: 652441
HIGH_NUMBER_OF_BYTES_USED: 669269

```

Each memory summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `memory_summary_by_account_by_event_name` has `USER`, `HOST`, and `EVENT_NAME` columns. Each row summarizes events for a given account (user and host combination) and event name.
- `memory_summary_by_host_by_event_name` has `HOST` and `EVENT_NAME` columns. Each row summarizes events for a given host and event name.
- `memory_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.
- `memory_summary_by_user_by_event_name` has `USER` and `EVENT_NAME` columns. Each row summarizes events for a given user and event name.
- `memory_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.

Each memory summary table has these summary columns containing aggregated values:

- `COUNT_ALLOC`, `COUNT_FREE`  
The aggregated numbers of calls to memory-allocation and memory-free functions.
- `SUM_NUMBER_OF_BYTES_ALLOC`, `SUM_NUMBER_OF_BYTES_FREE`  
The aggregated sizes of allocated and freed memory blocks.
- `CURRENT_COUNT_USED`  
The aggregated number of currently allocated blocks that have not been freed yet. This is a convenience column, equal to `COUNT_ALLOC - COUNT_FREE`.
- `CURRENT_NUMBER_OF_BYTES_USED`  
The aggregated size of currently allocated memory blocks that have not been freed yet. This is a convenience column, equal to `SUM_NUMBER_OF_BYTES_ALLOC - SUM_NUMBER_OF_BYTES_FREE`.
- `LOW_COUNT_USED`, `HIGH_COUNT_USED`  
The low and high water marks corresponding to the `CURRENT_COUNT_USED` column.
- `LOW_NUMBER_OF_BYTES_USED`, `HIGH_NUMBER_OF_BYTES_USED`  
The low and high water marks corresponding to the `CURRENT_NUMBER_OF_BYTES_USED` column.

`TRUNCATE TABLE` is permitted for memory summary tables. It has these effects:

- In general, truncation resets the baseline for statistics, but does not change the server state. That is, truncating a memory table does not free memory.

- `COUNT_ALLOC` and `COUNT_FREE` are reset to a new baseline, by reducing each counter by the same value.
- Likewise, `SUM_NUMBER_OF_BYTES_ALLOC` and `SUM_NUMBER_OF_BYTES_FREE` are reset to a new baseline.
- `LOW_COUNT_USED` and `HIGH_COUNT_USED` are reset to `CURRENT_COUNT_USED`.
- `LOW_NUMBER_OF_BYTES_USED` and `HIGH_NUMBER_OF_BYTES_USED` are reset to `CURRENT_NUMBER_OF_BYTES_USED`.

In addition, each memory summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `memory_summary_global_by_event_name`. For details, see [Section 25.12.8, “Performance Schema Connection Tables”](#).

## Memory Instrumentation Behavior

Memory instruments are listed in the `setup_instruments` table and have names of the form `memory/code_area/instrument_name`. Most memory instrumentation is disabled by default.

Instruments named with the prefix `memory/performance_schema/` expose how much memory is allocated for internal buffers in the Performance Schema itself. The `memory/performance_schema/` instruments are built in, always enabled, and cannot be disabled at startup or runtime. Built-in memory instruments are displayed only in the `memory_summary_global_by_event_name` table.

To control memory instrumentation state at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='memory/%=ON'
```

- Disable:

```
[mysqld]
performance-schema-instrument='memory/%=OFF'
```

To control memory instrumentation state at runtime, update the `ENABLED` column of the relevant instruments in the `setup_instruments` table:

- Enable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES'
WHERE NAME LIKE 'memory/%';
```

- Disable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME LIKE 'memory/%';
```

For memory instruments, the `TIMED` column in `setup_instruments` is ignored because memory operations are not timed.

When a thread in the server executes a memory allocation that has been instrumented, these rules apply:

- If the thread is not instrumented or the memory instrument is not enabled, the memory block allocated is not instrumented.
- Otherwise (that is, both the thread and the instrument are enabled), the memory block allocated is instrumented.

For deallocation, these rules apply:

- If a memory allocation operation was instrumented, the corresponding free operation is instrumented, regardless of the current instrument or thread enabled status.
- If a memory allocation operation was not instrumented, the corresponding free operation is not instrumented, regardless of the current instrument or thread enabled status.

For the per-thread statistics, the following rules apply.

When an instrumented memory block of size  $N$  is allocated, the Performance Schema makes these updates to memory summary table columns:

- `COUNT_ALLOC`: Increased by 1
- `CURRENT_COUNT_USED`: Increased by 1
- `HIGH_COUNT_USED`: Increased if `CURRENT_COUNT_USED` is a new maximum
- `SUM_NUMBER_OF_BYTES_ALLOC`: Increased by  $N$
- `CURRENT_NUMBER_OF_BYTES_USED`: Increased by  $N$
- `HIGH_NUMBER_OF_BYTES_USED`: Increased if `CURRENT_NUMBER_OF_BYTES_USED` is a new maximum

When an instrumented memory block is deallocated, the Performance Schema makes these updates to memory summary table columns:

- `COUNT_FREE`: Increased by 1
- `CURRENT_COUNT_USED`: Decreased by 1
- `LOW_COUNT_USED`: Decreased if `CURRENT_COUNT_USED` is a new minimum
- `SUM_NUMBER_OF_BYTES_FREE`: Increased by  $N$
- `CURRENT_NUMBER_OF_BYTES_USED`: Decreased by  $N$
- `LOW_NUMBER_OF_BYTES_USED`: Decreased if `CURRENT_NUMBER_OF_BYTES_USED` is a new minimum

For higher-level aggregates (global, by account, by user, by host), the same rules apply as expected for low and high water marks.

- `LOW_COUNT_USED` and `LOW_NUMBER_OF_BYTES_USED` are lower estimates. The value reported by the Performance Schema is guaranteed to be less than or equal to the lowest count or size of memory effectively used at runtime.
- `HIGH_COUNT_USED` and `HIGH_NUMBER_OF_BYTES_USED` are higher estimates. The value reported by the Performance Schema is guaranteed to be greater than or equal to the highest count or size of memory effectively used at runtime.

For lower estimates in summary tables other than `memory_summary_global_by_event_name`, it is possible for values to go negative if memory ownership is transferred between threads.

Here is an example of estimate computation; but note that estimate implementation is subject to change:

Thread 1 uses memory in the range from 1MB to 2MB during execution, as reported by the `LOW_NUMBER_OF_BYTES_USED` and `HIGH_NUMBER_OF_BYTES_USED` columns of the `memory_summary_by_thread_by_event_name` table.

Thread 2 uses memory in the range from 10MB to 12MB during execution, as reported likewise.

When these two threads belong to the same user account, the per-account summary estimates that this account used memory in the range from 11MB to 14MB. That is, the `LOW_NUMBER_OF_BYTES_USED` for the higher level aggregate is the sum of each `LOW_NUMBER_OF_BYTES_USED` (assuming the worst case). Likewise, the `HIGH_NUMBER_OF_BYTES_USED` for the higher level aggregate is the sum of each `HIGH_NUMBER_OF_BYTES_USED` (assuming the worst case).

11MB is a lower estimate that can occur only if both threads hit the low usage mark at the same time.

14MB is a higher estimate that can occur only if both threads hit the high usage mark at the same time.

The real memory usage for this account could have been in the range from 11.5MB to 13.5MB.

For capacity planning, reporting the worst case is actually the desired behavior, as it shows what can potentially happen when sessions are uncorrelated, which is typically the case.

## 25.12.15.10 Status Variable Summary Tables

### Note

The value of the `show_compatibility_56` system variable affects the information available from the tables described here. For details, see the description of that variable in [Section 5.1.7, “Server System Variables”](#).

The Performance Schema makes status variable information available in the tables described in [Section 25.12.14, “Performance Schema Status Variable Tables”](#). It also makes aggregated status variable information available in summary tables, described here. Each status variable summary table has one or more grouping columns to indicate how the table aggregates status values:

- `status_by_account` has `USER`, `HOST`, and `VARIABLE_NAME` columns to summarize status variables by account.
- `status_by_host` has `HOST` and `VARIABLE_NAME` columns to summarize status variables by the host from which clients connected.
- `status_by_user` has `USER` and `VARIABLE_NAME` columns to summarize status variables by client user name.

Each status variable summary table has this summary column containing aggregated values:

- `VARIABLE_VALUE`

The aggregated status variable value for active and terminated sessions.

The meaning of “account” in these tables is similar to its meaning in the MySQL grant tables in the `mysql` system database, in the sense that the term refers to a combination of user and host values. They differ in that, for grant tables, the host part of an account can be a pattern, whereas for Performance Schema tables, the host value is always a specific nonpattern host name.

Account status is collected when sessions terminate. The session status counters are added to the global status counters and the corresponding account status counters. If account statistics are not collected, the session status is added to host and user status, if host and user status are collected.

Account, host, and user statistics are not collected if the `performance_schema_accounts_size`, `performance_schema_hosts_size`, and `performance_schema_users_size` system variables, respectively, are set to 0.

The Performance Schema supports `TRUNCATE TABLE` for status variable summary tables as follows; in all cases, status for active sessions is unaffected:

- `status_by_account`: Aggregates account status from terminated sessions to user and host status, then resets account status.
- `status_by_host`: Resets aggregated host status from terminated sessions.
- `status_by_user`: Resets aggregated user status from terminated sessions.

`FLUSH STATUS` adds the session status from all active sessions to the global status variables, resets the status of all active sessions, and resets account, host, and user status values aggregated from disconnected sessions.

## 25.12.16 Performance Schema Miscellaneous Tables

The following sections describe tables that do not fall into the table categories discussed in the preceding sections:

- `host_cache`: Information from the internal host cache.
- `performance_timers`: Which event timers are available.
- `threads`: Information about server threads.

### 25.12.16.1 The `host_cache` Table

The MySQL server maintains an in-memory host cache that contains client host name and IP address information and is used to avoid Domain Name System (DNS) lookups. The `host_cache` table exposes the contents of this cache. The `host_cache_size` system variable controls the size of the host cache, as well as the size of the `host_cache` table. For operational and configuration information about the host cache, see [Section 5.1.11.2, “DNS Lookups and the Host Cache”](#).

Because the `host_cache` table exposes the contents of the host cache, it can be examined using `SELECT` statements. This may help you diagnose the causes of connection problems. The Performance Schema must be enabled or this table is empty.

The `host_cache` table has these columns:

- `IP`

The IP address of the client that connected to the server, expressed as a string.

- `HOST`

The resolved DNS host name for that client IP, or `NULL` if the name is unknown.

- `HOST_VALIDATED`

Whether the IP-to-host name-to-IP DNS resolution was performed successfully for the client IP. If `HOST_VALIDATED` is `YES`, the `HOST` column is used as the host name corresponding to the IP so that additional calls to DNS can be avoided. While `HOST_VALIDATED` is `NO`, DNS resolution is attempted for each connection attempt, until it eventually completes with either a valid result or a permanent error. This information enables the server to avoid caching bad or missing host names during temporary DNS failures, which would negatively affect clients forever.

- `SUM_CONNECT_ERRORS`

The number of connection errors that are deemed “blocking” (assessed against the `max_connect_errors` system variable). Only protocol handshake errors are counted, and only for hosts that passed validation (`HOST_VALIDATED = YES`).

Once `SUM_CONNECT_ERRORS` for a given host reaches the value of `max_connect_errors`, new connections from that host are blocked. The `SUM_CONNECT_ERRORS` value can exceed the `max_connect_errors` value because multiple connection attempts from a host can occur

simultaneously while the host is not blocked. Any or all of them can fail, independently incrementing `SUM_CONNECT_ERRORS`, possibly beyond the value of `max_connect_errors`.

Suppose that `max_connect_errors` is 200 and `SUM_CONNECT_ERRORS` for a given host is 199. If 10 clients attempt to connect from that host simultaneously, none of them are blocked because `SUM_CONNECT_ERRORS` has not reached 200. If blocking errors occur for five of the clients, `SUM_CONNECT_ERRORS` is increased by one for each client, for a resulting `SUM_CONNECT_ERRORS` value of 204. The other five clients succeed and are not blocked because the value of `SUM_CONNECT_ERRORS` when their connection attempts began had not reached 200. New connections from the host that begin after `SUM_CONNECT_ERRORS` reaches 200 are blocked.

- `COUNT_HOST_BLOCKED_ERRORS`

The number of connections that were blocked because `SUM_CONNECT_ERRORS` exceeded the value of the `max_connect_errors` system variable.

- `COUNT_NAMEINFO_TRANSIENT_ERRORS`

The number of transient errors during IP-to-host name DNS resolution.

- `COUNT_NAMEINFO_PERMANENT_ERRORS`

The number of permanent errors during IP-to-host name DNS resolution.

- `COUNT_FORMAT_ERRORS`

The number of host name format errors. MySQL does not perform matching of `Host` column values in the `mysql.user` system table against host names for which one or more of the initial components of the name are entirely numeric, such as `1.2.example.com`. The client IP address is used instead. For the rationale why this type of matching does not occur, see [Section 6.2.4, “Specifying Account Names”](#).

- `COUNT_ADDRINFO_TRANSIENT_ERRORS`

The number of transient errors during host name-to-IP reverse DNS resolution.

- `COUNT_ADDRINFO_PERMANENT_ERRORS`

The number of permanent errors during host name-to-IP reverse DNS resolution.

- `COUNT_FCRDNS_ERRORS`

The number of forward-confirmed reverse DNS errors. These errors occur when IP-to-host name-to-IP DNS resolution produces an IP address that does not match the client originating IP address.

- `COUNT_HOST_ACL_ERRORS`

The number of errors that occur because no users are permitted to connect from the client host. In such cases, the server returns `ER_HOST_NOT_PRIVILEGED` and does not even ask for a user name or password.

- `COUNT_NO_AUTH_PLUGIN_ERRORS`

The number of errors due to requests for an unavailable authentication plugin. A plugin can be unavailable if, for example, it was never loaded or a load attempt failed.

- `COUNT_AUTH_PLUGIN_ERRORS`

The number of errors reported by authentication plugins.

An authentication plugin can report different error codes to indicate the root cause of a failure. Depending on the type of error, one of these columns is

incremented: `COUNT_AUTHENTICATION_ERRORS`, `COUNT_AUTH_PLUGIN_ERRORS`, `COUNT_HANDSHAKE_ERRORS`. New return codes are an optional extension to the existing plugin API. Unknown or unexpected plugin errors are counted in the `COUNT_AUTH_PLUGIN_ERRORS` column.

- `COUNT_HANDSHAKE_ERRORS`

The number of errors detected at the wire protocol level.

- `COUNT_PROXY_USER_ERRORS`

The number of errors detected when proxy user A is proxied to another user B who does not exist.

- `COUNT_PROXY_USER_ACL_ERRORS`

The number of errors detected when proxy user A is proxied to another user B who does exist but for whom A does not have the `PROXY` privilege.

- `COUNT_AUTHENTICATION_ERRORS`

The number of errors caused by failed authentication.

- `COUNT_SSL_ERRORS`

The number of errors due to SSL problems.

- `COUNT_MAX_USER_CONNECTIONS_ERRORS`

The number of errors caused by exceeding per-user connection quotas. See [Section 6.2.16, “Setting Account Resource Limits”](#).

- `COUNT_MAX_USER_CONNECTIONS_PER_HOUR_ERRORS`

The number of errors caused by exceeding per-user connections-per-hour quotas. See [Section 6.2.16, “Setting Account Resource Limits”](#).

- `COUNT_DEFAULT_DATABASE_ERRORS`

The number of errors related to the default database. For example, the database does not exist or the user has no privileges to access it.

- `COUNT_INIT_CONNECT_ERRORS`

The number of errors caused by execution failures of statements in the `init_connect` system variable value.

- `COUNT_LOCAL_ERRORS`

The number of errors local to the server implementation and not related to the network, authentication, or authorization. For example, out-of-memory conditions fall into this category.

- `COUNT_UNKNOWN_ERRORS`

The number of other, unknown errors not accounted for by other columns in this table. This column is reserved for future use, in case new error conditions must be reported, and if preserving the backward compatibility and structure of the `host_cache` table is required.

- `FIRST_SEEN`

The timestamp of the first connection attempt seen from the client in the `IP` column.

- `LAST_SEEN`

The timestamp of the most recent connection attempt seen from the client in the `IP` column.

- **FIRST\_ERROR\_SEEN**

The timestamp of the first error seen from the client in the `IP` column.

- **LAST\_ERROR\_SEEN**

The timestamp of the most recent error seen from the client in the `IP` column.

`TRUNCATE TABLE` is permitted for the `host_cache` table. It requires the `DROP` privilege for the table. Truncating the table flushes the host cache, which has the effects described in [Flushing the Host Cache](#).

## 25.12.16.2 The performance\_timers Table

The `performance_timers` table shows which event timers are available:

| TIMER_NAME  | TIMER_FREQUENCY | TIMER_RESOLUTION | TIMER_OVERHEAD |
|-------------|-----------------|------------------|----------------|
| CYCLE       | 2389029850      | 1                | 72             |
| NANOSECOND  | 1000000000      | 1                | 112            |
| MICROSECOND | 1000000         | 1                | 136            |
| MILLISECOND | 1036            | 1                | 168            |
| TICK        | 105             | 1                | 2416           |

If the values associated with a given timer name are `NULL`, that timer is not supported on your platform. The rows that do not contain `NULL` indicate which timers you can use in `setup_timers`. For an explanation of how event timing occurs, see [Section 25.4.1, “Performance Schema Event Timing”](#).

### Note

As of MySQL 5.7.21, the Performance Schema `setup_timers` table is deprecated and is removed in MySQL 8.0, as is the `TICKS` row in the `performance_timers` table.

The `performance_timers` table has these columns:

- **TIMER\_NAME**

The name by which to refer to the timer when configuring the `setup_timers` table.

- **TIMER\_FREQUENCY**

The number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. For example, on a system with a 2.4GHz processor, the `CYCLE` may be close to 2400000000.

- **TIMER\_RESOLUTION**

Indicates the number of timer units by which timer values increase. If a timer has a resolution of 10, its value increases by 10 each time.

- **TIMER\_OVERHEAD**

The minimal number of cycles of overhead to obtain one timing with the given timer. The Performance Schema determines this value by invoking the timer 20 times during initialization and picking the smallest value. The total overhead really is twice this amount because the instrumentation invokes the timer at the start and end of each event. The timer code is called only for timed events, so this overhead does not apply for nontimed events.

`TRUNCATE TABLE` is not permitted for the `performance_timers` table.

### 25.12.16.3 The threads Table

The `threads` table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring and historical event logging are enabled for it:

```
mysql> SELECT * FROM performance_schema.threads\G
***** 1. row *****
 THREAD_ID: 1
 NAME: thread/sql/main
 TYPE: BACKGROUND
 PROCESSLIST_ID: NULL
 PROCESSLIST_USER: NULL
 PROCESSLIST_HOST: NULL
 PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: NULL
 PROCESSLIST_TIME: 80284
 PROCESSLIST_STATE: NULL
 PROCESSLIST_INFO: NULL
 PARENT_THREAD_ID: NULL
 ROLE: NULL
 INSTRUMENTED: YES
 HISTORY: YES
 CONNECTION_TYPE: NULL
 THREAD_OS_ID: 489803
...
***** 4. row *****
 THREAD_ID: 51
 NAME: thread/sql/one_connection
 TYPE: FOREGROUND
 PROCESSLIST_ID: 34
 PROCESSLIST_USER: isabella
 PROCESSLIST_HOST: localhost
 PROCESSLIST_DB: performance_schema
PROCESSLIST_COMMAND: Query
 PROCESSLIST_TIME: 0
 PROCESSLIST_STATE: Sending data
 PROCESSLIST_INFO: SELECT * FROM performance_schema.threads
 PARENT_THREAD_ID: 1
 ROLE: NULL
 INSTRUMENTED: YES
 HISTORY: YES
 CONNECTION_TYPE: SSL/TLS
 THREAD_OS_ID: 755399
...
...
```

When the Performance Schema initializes, it populates the `threads` table based on the threads in existence then. Thereafter, a new row is added each time the server creates a thread.

The `INSTRUMENTED` and `HISTORY` column values for new threads are determined by the contents of the `setup_actors` table. For information about how to use the `setup_actors` table to control these columns, see [Section 25.4.6, “Pre-Filtering by Thread”](#).

Removal of rows from the `threads` table occurs when threads end. For a thread associated with a client session, removal occurs when the session ends. If a client has auto-reconnect enabled and the session reconnects after a disconnect, the session becomes associated with a new row in the `threads` table that has a different `PROCESSLIST_ID` value. The initial `INSTRUMENTED` and `HISTORY` values for the new thread may be different from those of the original thread: The `setup_actors` table may have changed in the meantime, and if the `INSTRUMENTED` or `HISTORY` value for the original thread was changed after the row was initialized, the change does not carry over to the new thread.

You can enable or disable thread monitoring (that is, whether events executed by the thread are instrumented) and historical event logging. To control the initial `INSTRUMENTED` and `HISTORY` values for new foreground threads, use the `setup_actors` table. To control these aspects of existing threads, set the `INSTRUMENTED` and `HISTORY` columns of `threads` table rows. (For more information about the conditions under which thread monitoring and historical event logging occur, see the descriptions of the `INSTRUMENTED` and `HISTORY` columns.)

For a comparison of the `threads` table columns with names having a prefix of `PROCESSLIST_` to other process information sources, see [Sources of Process Information](#).

### Important

For thread information sources other than the `threads` table, information about threads for other users is shown only if the current user has the `PROCESS` privilege. That is not true of the `threads` table; all rows are shown to any user who has the `SELECT` privilege for the table. Users who should not be able to see threads for other users by accessing the `threads` table should not be given the `SELECT` privilege for it.

The `threads` table has these columns:

- `THREAD_ID`

A unique thread identifier.

- `NAME`

The name associated with the thread instrumentation code in the server. For example, `thread/sql/one_connection` corresponds to the thread function in the code responsible for handling a user connection, and `thread/sql/main` stands for the `main()` function of the server.

- `TYPE`

The thread type, either `FOREGROUND` or `BACKGROUND`. User connection threads are foreground threads. Threads associated with internal server activity are background threads. Examples are internal InnoDB threads, “binlog dump” threads sending information to replicas, and replication I/O and SQL threads.

- `PROCESSLIST_ID`

For a foreground thread (associated with a user connection), this is the connection identifier. This is the same value displayed in the `ID` column of the `INFORMATION_SCHEMA PROCESSLIST` table, displayed in the `Id` column of `SHOW PROCESSLIST` output, and returned by the `CONNECTION_ID()` function within the thread.

For a background thread (not associated with a user connection), `PROCESSLIST_ID` is `NULL`, so the values are not unique.

- `PROCESSLIST_USER`

The user associated with a foreground thread, `NULL` for a background thread.

- `PROCESSLIST_HOST`

The host name of the client associated with a foreground thread, `NULL` for a background thread.

Unlike the `HOST` column of the `INFORMATION_SCHEMA PROCESSLIST` table or the `Host` column of `SHOW PROCESSLIST` output, the `PROCESSLIST_HOST` column does not include the port number for TCP/IP connections. To obtain this information from the Performance Schema, enable the socket instrumentation (which is not enabled by default) and examine the `socket_instances` table:

```
mysql> SELECT * FROM performance_schema.setup_instruments
 WHERE NAME LIKE 'wait/io/socket%';
+-----+-----+-----+
| NAME | ENABLED | TIMED |
+-----+-----+-----+
| wait/io/socket/sql/server_tcpip_socket | NO | NO |
| wait/io/socket/sql/server_unix_socket | NO | NO |
| wait/io/socket/sql/client_connection | NO | NO |
+-----+-----+-----+
3 rows in set (0.01 sec)
```

```

mysql> UPDATE performance_schema.setup_instruments
 SET ENABLED='YES'
 WHERE NAME LIKE 'wait/io/socket%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3 Changed: 3 Warnings: 0

mysql> SELECT * FROM performance_schema.socket_instances\G
***** 1. row *****
EVENT_NAME: wait/io/socket/sql/client_connection
OBJECT_INSTANCE_BEGIN: 140612577298432
THREAD_ID: 31
SOCKET_ID: 53
IP: ::ffff:127.0.0.1
PORT: 55642
STATE: ACTIVE
...

```

- [PROCESSLIST\\_DB](#)

The default database for the thread, or `NULL` if none has been selected.

- [PROCESSLIST\\_COMMAND](#)

For foreground threads, the type of command the thread is executing on behalf of the client, or `Sleep` if the session is idle. For descriptions of thread commands, see [Section 8.14, “Examining Server Thread \(Process\) Information”](#). The value of this column corresponds to the `COM_XXX` commands of the client/server protocol and `Com_XXX` status variables. See [Section 5.1.9, “Server Status Variables”](#)

Background threads do not execute commands on behalf of clients, so this column may be `NULL`.

- [PROCESSLIST\\_TIME](#)

The time in seconds that the thread has been in its current state. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See [Section 16.2.3, “Replication Threads”](#).

- [PROCESSLIST\\_STATE](#)

An action, event, or state that indicates what the thread is doing. For descriptions of `PROCESSLIST_STATE` values, see [Section 8.14, “Examining Server Thread \(Process\) Information”](#). If the value is `NULL`, the thread may correspond to an idle client session or the work it is doing is not instrumented with stages.

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that bears investigation.

- [PROCESSLIST\\_INFO](#)

The statement the thread is executing, or `NULL` if it is executing no statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the `PROCESSLIST_INFO` value shows the `SELECT` statement.

- [PARENT\\_THREAD\\_ID](#)

If this thread is a subthread (spawned by another thread), this is the `THREAD_ID` value of the spawning thread.

- [ROLE](#)

Unused.

- [INSTRUMENTED](#)

Whether events executed by the thread are instrumented. The value is `YES` or `NO`.

- For foreground threads, the initial `INSTRUMENTED` value is determined by whether the user account associated with the thread matches any row in the `setup_actors` table. Matching is based on the values of the `PROCESSLIST_USER` and `PROCESSLIST_HOST` columns.

If the thread spawns a subthread, matching occurs again for the `threads` table row created for the subthread.

- For background threads, `INSTRUMENTED` is `YES` by default. `setup_actors` is not consulted because there is no associated user for background threads.
- For any thread, its `INSTRUMENTED` value can be changed during the lifetime of the thread.

For monitoring of events executed by the thread to occur, these things must be true:

- The `thread_instrumentation` consumer in the `setup_consumers` table must be `YES`.
- The `threads.INSTRUMENTED` column must be `YES`.
- Monitoring occurs only for those thread events produced from instruments that have the `ENABLED` column set to `YES` in the `setup_instruments` table.

- **HISTORY**

Whether to log historical events for the thread. The value is `YES` or `NO`.

- For foreground threads, the initial `HISTORY` value is determined by whether the user account associated with the thread matches any row in the `setup_actors` table. Matching is based on the values of the `PROCESSLIST_USER` and `PROCESSLIST_HOST` columns.

If the thread spawns a subthread, matching occurs again for the `threads` table row created for the subthread.

- For background threads, `HISTORY` is `YES` by default. `setup_actors` is not consulted because there is no associated user for background threads.
- For any thread, its `HISTORY` value can be changed during the lifetime of the thread.

For historical event logging for the thread to occur, these things must be true:

- The appropriate history-related consumers in the `setup_consumers` table must be enabled. For example, wait event logging in the `events_waits_history` and `events_waits_history_long` tables requires the corresponding `events_waits_history` and `events_waits_history_long` consumers to be `YES`.
- The `threads.HISTORY` column must be `YES`.
- Logging occurs only for those thread events produced from instruments that have the `ENABLED` column set to `YES` in the `setup_instruments` table.

- **CONNECTION\_TYPE**

The protocol used to establish the connection, or `NULL` for background threads. Permitted values are `TCP/IP` (TCP/IP connection established without encryption), `SSL/TLS` (TCP/IP connection established with encryption), `Socket` (Unix socket file connection), `Named Pipe` (Windows named pipe connection), and `Shared Memory` (Windows shared memory connection).

- **THREAD\_OS\_ID**

The thread or task identifier as defined by the underlying operating system, if there is one:

- When a MySQL thread is associated with the same operating system thread for its lifetime, `THREAD_OS_ID` contains the operating system thread ID.
- When a MySQL thread is not associated with the same operating system thread for its lifetime, `THREAD_OS_ID` contains `NULL`. This is typical for user sessions when the thread pool plugin is used (see Section 5.5.3, “MySQL Enterprise Thread Pool”).

For Windows, `THREAD_OS_ID` corresponds to the thread ID visible in Process Explorer (<https://technet.microsoft.com/en-us/sysinternals/bb896653.aspx>).

For Linux, `THREAD_OS_ID` corresponds to the value of the `gettid()` function. This value is exposed, for example, using the `perf` or `ps -L` commands, or in the `proc` file system (`/proc/[pid]/task/[tid]`). For more information, see the `perf-stat(1)`, `ps(1)`, and `proc(5)` man pages.

`TRUNCATE TABLE` is not permitted for the `threads` table.

## 25.13 Performance Schema Option and Variable Reference

Table 25.13 Performance Schema Variable Reference

| Name                                                                    | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dy |
|-------------------------------------------------------------------------|----------|-------------|------------|------------|-----------|----|
| <code>performance_schema</code>                                         | Yes      | Yes         | Yes        |            | Global    | No |
| <code>Performance_schema_accounts_lost</code>                           |          |             |            | Yes        | Global    | No |
| <code>performance_schema_accounts_size</code>                           | Yes      | Yes         | Yes        |            | Global    | No |
| <code>Performance_schema_cond_classes_lost</code>                       |          |             |            | Yes        | Global    | No |
| <code>Performance_schema_cond_instances_lost</code>                     |          |             |            | Yes        | Global    | No |
| <code>performance-schema-consumer-events-stages-current</code>          | Yes      | Yes         |            |            |           |    |
| <code>performance-schema-consumer-events-stages-history</code>          | Yes      | Yes         |            |            |           |    |
| <code>performance-schema-consumer-events-stages-history-long</code>     | Yes      | Yes         |            |            |           |    |

## 25.14 Performance Schema Command Options

Performance Schema parameters can be specified at server startup on the command line or in option files to configure Performance Schema instruments and consumers. Runtime configuration is also possible in many cases (see [Section 25.4, “Performance Schema Runtime Configuration”](#)), but startup configuration must be used when runtime configuration is too late to affect instruments that have already been initialized during the startup process.

Performance Schema consumers and instruments can be configured at startup using the following syntax. For additional details, see [Section 25.3, “Performance Schema Startup Configuration”](#).

- `--performance-schema-consumer-consumer_name=value`

Configure a Performance Schema consumer. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent. Options for configuring individual consumers are detailed later in this section.

- `--performance-schema-instrument=instrument_name=value`

Configure a Performance Schema instrument. The name may be given as a pattern to configure instruments that match the pattern.

The following items configure individual consumers:

- `--performance-schema-consumer-events-stages-current=value`

Configure the `events-stages-current` consumer.

- `--performance-schema-consumer-events-stages-history=value`

Configure the `events-stages-history` consumer.

- `--performance-schema-consumer-events-stages-history-long=value`

Configure the `events-stages-history-long` consumer.

- `--performance-schema-consumer-events-statements-current=value`

Configure the `events-statements-current` consumer.

- `--performance-schema-consumer-events-statements-history=value`

Configure the `events-statements-history` consumer.

- `--performance-schema-consumer-events-statements-history-long=value`

Configure the `events-statements-history-long` consumer.

- `--performance-schema-consumer-events-transactions-current=value`

Configure the Performance Schema `events-transactions-current` consumer.

- `--performance-schema-consumer-events-transactions-history=value`

Configure the Performance Schema `events-transactions-history` consumer.

- `--performance-schema-consumer-events-transactions-history-long=value`

Configure the Performance Schema `events-transactions-history-long` consumer.

- `--performance-schema-consumer-events-waits-current=value`

Configure the `events-waits-current` consumer.

- `--performance-schema-consumer-events-waits-history=value`

Configure the `events-waits-history` consumer.

- `--performance-schema-consumer-events-waits-history-long=value`

Configure the `events-waits-history-long` consumer.

- `--performance-schema-consumer-global-instrumentation=value`

Configure the `global-instrumentation` consumer.

- `--performance-schema-consumer-statements-digest=value`

Configure the `statements-digest` consumer.

- `--performance-schema-consumer-thread-instrumentation=value`

Configure the `thread-instrumentation` consumer.

## 25.15 Performance Schema System Variables

The Performance Schema implements several system variables that provide configuration information:

| Variable_name                                            | Value |
|----------------------------------------------------------|-------|
| performance_schema                                       | ON    |
| performance_schema_accounts_size                         | -1    |
| performance_schema_digests_size                          | 10000 |
| performance_schema_events_stages_history_long_size       | 10000 |
| performance_schema_events_stages_history_size            | 10    |
| performance_schema_events_statements_history_long_size   | 10000 |
| performance_schema_events_statements_history_size        | 10    |
| performance_schema_events_transactions_history_long_size | 10000 |
| performance_schema_events_transactions_history_size      | 10    |
| performance_schema_events_waits_history_long_size        | 10000 |
| performance_schema_events_waits_history_size             | 10    |
| performance_schema_hosts_size                            | -1    |
| performance_schema_max_cond_classes                      | 80    |
| performance_schema_max_cond_instances                    | -1    |
| performance_schema_max_digest_length                     | 1024  |
| performance_schema_max_file_classes                      | 50    |
| performance_schema_max_file_handles                      | 32768 |
| performance_schema_max_file_instances                    | -1    |
| performance_schema_max_index_stat                        | -1    |
| performance_schema_max_memory_classes                    | 320   |
| performance_schema_max_metadata_locks                    | -1    |
| performance_schema_max_mutex_classes                     | 200   |
| performance_schema_max_mutex_instances                   | -1    |
| performance_schema_max_prepared_statements_instances     | -1    |
| performance_schema_max_program_instances                 | -1    |
| performance_schema_max_rwlock_classes                    | 40    |
| performance_schema_max_rwlock_instances                  | -1    |
| performance_schema_max_socket_classes                    | 10    |
| performance_schema_max_socket_instances                  | -1    |
| performance_schema_max_sql_text_length                   | 1024  |

|                                               |     |
|-----------------------------------------------|-----|
| performance_schema_max_stage_classes          | 150 |
| performance_schema_max_statement_classes      | 192 |
| performance_schema_max_statement_stack        | 10  |
| performance_schema_max_table_handles          | -1  |
| performance_schema_max_table_instances        | -1  |
| performance_schema_max_table_lock_stat        | -1  |
| performance_schema_max_thread_classes         | 50  |
| performance_schema_max_thread_instances       | -1  |

| performance_schema_setup_actors_size          | -1  |
| performance_schema_setup_objects_size         | -1  |
| performance_schema_users_size                 | -1  |

Performance Schema system variables can be set at server startup on the command line or in option files, and many can be set at runtime. See [Section 25.13, “Performance Schema Option and Variable Reference”](#).

The Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For more information, see [Section 25.3, “Performance Schema Startup Configuration”](#).

Performance Schema system variables have the following meanings:

- [performance\\_schema](#)

|                     |                                 |
|---------------------|---------------------------------|
| Command-Line Format | --performance-schema[={OFF ON}] |
| System Variable     | performance_schema              |
| Scope               | Global                          |
| Dynamic             | No                              |
| Type                | Boolean                         |
| Default Value       | ON                              |

The value of this variable is `ON` or `OFF` to indicate whether the Performance Schema is enabled. By default, the value is `ON`. At server startup, you can specify this variable with no value or a value of `ON` or `1` to enable it, or with a value of `OFF` or `0` to disable it.

Even when the Performance Schema is disabled, it continues to populate the `global_variables`, `session_variables`, `global_status`, and `session_status` tables. This occurs as necessary to permit the results for the `SHOW VARIABLES` and `SHOW STATUS` statements to be drawn from those tables, depending on the setting of the `show_compatibility_56` system variable.

- [performance\\_schema\\_accounts\\_size](#)

|                     |                                                              |
|---------------------|--------------------------------------------------------------|
| Command-Line Format | --performance-schema-accounts-size=#                         |
| System Variable     | performance_schema_accounts_size                             |
| Scope               | Global                                                       |
| Dynamic             | No                                                           |
| Type                | Integer                                                      |
| Default Value       | -1 (signifies autoscaling; do not assign this literal value) |
| Minimum Value       | -1 (signifies autoscaling; do not assign this literal value) |
| Maximum Value       | 1048576                                                      |

The number of rows in the `accounts` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `accounts` table or status variable information in the `status_by_account` table.

- [performance\\_schema\\_digests\\_size](#)

|                     |                                                                          |
|---------------------|--------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-digests-size=#</code>                         |
| System Variable     | <code>performance_schema_digests_size</code>                             |
| Scope               | Global                                                                   |
| Dynamic             | No                                                                       |
| Type                | Integer                                                                  |
| Default Value       | <code>-1</code> (signifies autosizing; do not assign this literal value) |
| Minimum Value       | <code>-1</code>                                                          |
| Maximum Value       | <code>1048576</code>                                                     |

The maximum number of rows in the `events_statements_summary_by_digest` table. If this maximum is exceeded such that a digest cannot be instrumented, the Performance Schema increments the `Performance_schema_digest_lost` status variable.

For more information about statement digesting, see [Section 25.10, “Performance Schema Statement Digests”](#).

- `performance_schema_events_stages_history_long_size`

|                     |                                                                          |
|---------------------|--------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-events-stages-history-long-size=#</code>      |
| System Variable     | <code>performance_schema_events_stages_history_long_size</code>          |
| Scope               | Global                                                                   |
| Dynamic             | No                                                                       |
| Type                | Integer                                                                  |
| Default Value       | <code>-1</code> (signifies autosizing; do not assign this literal value) |

The number of rows in the `events_stages_history_long` table.

- `performance_schema_events_stages_history_size`

|                     |                                                                          |
|---------------------|--------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-events-stages-history-size=#</code>           |
| System Variable     | <code>performance_schema_events_stages_history_size</code>               |
| Scope               | Global                                                                   |
| Dynamic             | No                                                                       |
| Type                | Integer                                                                  |
| Default Value       | <code>-1</code> (signifies autosizing; do not assign this literal value) |

The number of rows per thread in the `events_stages_history` table.

- `performance_schema_events_statements_history_long_size`

|                     |                                                                         |
|---------------------|-------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-events-statements-history-long-size=#</code> |
| System Variable     | <code>performance_schema_events_statements_history_long_size</code>     |
| Scope               | Global                                                                  |
| Dynamic             | No                                                                      |
| Type                | Integer                                                                 |

|               |                                                                          |
|---------------|--------------------------------------------------------------------------|
| Default Value | <code>-1</code> (signifies autosizing; do not assign this literal value) |
|---------------|--------------------------------------------------------------------------|

The number of rows in the `events_statements_history_long` table.

- `performance_schema_events_statements_history_size`

|                     |                                                                          |
|---------------------|--------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-events-statements-history-size=#</code>       |
| System Variable     | <code>performance_schema_events_statements_history_size</code>           |
| Scope               | Global                                                                   |
| Dynamic             | No                                                                       |
| Type                | Integer                                                                  |
| Default Value       | <code>-1</code> (signifies autosizing; do not assign this literal value) |

The number of rows per thread in the `events_statements_history` table.

- `performance_schema_events_transactions_history_long_size`

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-events-transactions-history-long-size=#</code> |
| System Variable     | <code>performance_schema_events_transactions_history_long_size</code>     |
| Scope               | Global                                                                    |
| Dynamic             | No                                                                        |
| Type                | Integer                                                                   |
| Default Value       | <code>-1</code> (signifies autosizing; do not assign this literal value)  |

The number of rows in the `events_transactions_history_long` table.

- `performance_schema_events_transactions_history_size`

|                     |                                                                          |
|---------------------|--------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-events-transactions-history-size=#</code>     |
| System Variable     | <code>performance_schema_events_transactions_history_size</code>         |
| Scope               | Global                                                                   |
| Dynamic             | No                                                                       |
| Type                | Integer                                                                  |
| Default Value       | <code>-1</code> (signifies autosizing; do not assign this literal value) |

The number of rows per thread in the `events_transactions_history` table.

- `performance_schema_events_waits_history_long_size`

|                     |                                                                          |
|---------------------|--------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-events-waits-history-long-size=#</code>       |
| System Variable     | <code>performance_schema_events_waits_history_long_size</code>           |
| Scope               | Global                                                                   |
| Dynamic             | No                                                                       |
| Type                | Integer                                                                  |
| Default Value       | <code>-1</code> (signifies autosizing; do not assign this literal value) |

The number of rows in the `events_waits_history_long` table.

- `performance_schema_events_waits_history_size`

|                     |                                                                          |
|---------------------|--------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-events-waits-history-size=#</code>            |
| System Variable     | <code>performance_schema_events_waits_history_size</code>                |
| Scope               | Global                                                                   |
| Dynamic             | No                                                                       |
| Type                | Integer                                                                  |
| Default Value       | <code>-1</code> (signifies autosizing; do not assign this literal value) |

The number of rows per thread in the `events_waits_history` table.

- `performance_schema_hosts_size`

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-hosts-size=#</code>                            |
| System Variable     | <code>performance_schema_hosts_size</code>                                |
| Scope               | Global                                                                    |
| Dynamic             | No                                                                        |
| Type                | Integer                                                                   |
| Default Value       | <code>-1</code> (signifies autoscaling; do not assign this literal value) |
| Minimum Value       | <code>-1</code> (signifies autoscaling; do not assign this literal value) |
| Maximum Value       | <code>1048576</code>                                                      |

The number of rows in the `hosts` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `hosts` table or status variable information in the `status_by_host` table.

- `performance_schema_max_cond_classes`

|                     |                                                      |
|---------------------|------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-cond-classes=#</code> |
| System Variable     | <code>performance_schema_max_cond_classes</code>     |
| Scope               | Global                                               |
| Dynamic             | No                                                   |
| Type                | Integer                                              |
| Default Value       | <code>80</code>                                      |
| Minimum Value       | <code>0</code>                                       |
| Maximum Value       | <code>256</code>                                     |

The maximum number of condition instruments. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- `performance_schema_max_cond_instances`

|                     |                                                        |
|---------------------|--------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-cond-instances=#</code> |
| System Variable     | <code>performance_schema_max_cond_instances</code>     |
| Scope               | Global                                                 |
| Dynamic             | No                                                     |
| Type                | Integer                                                |

|               |                                                                           |
|---------------|---------------------------------------------------------------------------|
| Default Value | <code>-1</code> (signifies autoscaling; do not assign this literal value) |
|---------------|---------------------------------------------------------------------------|

The maximum number of instrumented condition objects. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- `performance_schema_max_digest_length`

|                     |                                                       |
|---------------------|-------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-digest-length=#</code> |
| System Variable     | <code>performance_schema_max_digest_length</code>     |
| Scope               | Global                                                |
| Dynamic             | No                                                    |
| Type                | Integer                                               |
| Default Value       | <code>1024</code>                                     |
| Minimum Value       | <code>0</code>                                        |
| Maximum Value       | <code>1048576</code>                                  |

The maximum number of bytes of memory reserved per statement for computation of normalized statement digest values in the Performance Schema. This variable is related to `max_digest_length`; see the description of that variable in [Section 5.1.7, “Server System Variables”](#).

For more information about statement digesting, including considerations regarding memory use, see [Section 25.10, “Performance Schema Statement Digests”](#).

- `performance_schema_max_file_classes`

|                     |                                                      |
|---------------------|------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-file-classes=#</code> |
| System Variable     | <code>performance_schema_max_file_classes</code>     |
| Scope               | Global                                               |
| Dynamic             | No                                                   |
| Type                | Integer                                              |
| Default Value       | <code>80</code>                                      |
| Minimum Value       | <code>0</code>                                       |
| Maximum Value       | <code>256</code>                                     |

The maximum number of file instruments. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- `performance_schema_max_file_handles`

|                     |                                                      |
|---------------------|------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-file-handles=#</code> |
| System Variable     | <code>performance_schema_max_file_handles</code>     |
| Scope               | Global                                               |
| Dynamic             | No                                                   |
| Type                | Integer                                              |
| Default Value       | <code>32768</code>                                   |

The maximum number of opened file objects. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

The value of `performance_schema_max_file_handles` should be greater than the value of `open_files_limit`: `open_files_limit` affects the maximum number of open file handles the

server can support and `performance_schema_max_file_handles` affects how many of these file handles can be instrumented.

- `performance_schema_max_file_instances`

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-file-instances=#</code>                    |
| System Variable     | <code>performance_schema_max_file_instances</code>                        |
| Scope               | Global                                                                    |
| Dynamic             | No                                                                        |
| Type                | Integer                                                                   |
| Default Value       | <code>-1</code> (signifies autoscaling; do not assign this literal value) |

The maximum number of instrumented file objects. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- `performance_schema_max_index_stat`

|                     |                                                                          |
|---------------------|--------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-index-stat=#</code>                       |
| System Variable     | <code>performance_schema_max_index_stat</code>                           |
| Scope               | Global                                                                   |
| Dynamic             | No                                                                       |
| Type                | Integer                                                                  |
| Default Value       | <code>-1</code> (signifies autosizing; do not assign this literal value) |

The maximum number of indexes for which the Performance Schema maintains statistics. If this maximum is exceeded such that index statistics are lost, the Performance Schema increments the `Performance_schema_index_stat_lost` status variable. The default value is autosized using the value of `performance_schema_max_table_instances`.

- `performance_schema_max_memory_classes`

|                     |                                                        |
|---------------------|--------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-memory-classes=#</code> |
| System Variable     | <code>performance_schema_max_memory_classes</code>     |
| Scope               | Global                                                 |
| Dynamic             | No                                                     |
| Type                | Integer                                                |
| Default Value       | <code>320</code>                                       |

The maximum number of memory instruments. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- `performance_schema_max_metadata_locks`

|                     |                                                        |
|---------------------|--------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-metadata-locks=#</code> |
| System Variable     | <code>performance_schema_max_metadata_locks</code>     |
| Scope               | Global                                                 |
| Dynamic             | No                                                     |
| Type                | Integer                                                |

|               |                                                                           |
|---------------|---------------------------------------------------------------------------|
| Default Value | <code>-1</code> (signifies autoscaling; do not assign this literal value) |
|---------------|---------------------------------------------------------------------------|

The maximum number of metadata lock instruments. This value controls the size of the `metadata_locks` table. If this maximum is exceeded such that a metadata lock cannot be instrumented, the Performance Schema increments the `Performance_schema_metadata_lock_lost` status variable.

- `performance_schema_max_mutex_classes`

|                     |                                                       |
|---------------------|-------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-mutex-classes=#</code> |
| System Variable     | <code>performance_schema_max_mutex_classes</code>     |
| Scope               | Global                                                |
| Dynamic             | No                                                    |
| Type                | Integer                                               |
| Default Value       | <code>200</code>                                      |
| Minimum Value       | <code>0</code>                                        |
| Maximum Value       | <code>256</code>                                      |

The maximum number of mutex instruments. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- `performance_schema_max_mutex_instances`

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-mutex-instances=#</code>                   |
| System Variable     | <code>performance_schema_max_mutex_instances</code>                       |
| Scope               | Global                                                                    |
| Dynamic             | No                                                                        |
| Type                | Integer                                                                   |
| Default Value       | <code>-1</code> (signifies autoscaling; do not assign this literal value) |

The maximum number of instrumented mutex objects. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- `performance_schema_max_prepared_statements_instances`

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-prepared-statements-instances=#</code>     |
| System Variable     | <code>performance_schema_max_prepared_statements_instances</code>         |
| Scope               | Global                                                                    |
| Dynamic             | No                                                                        |
| Type                | Integer                                                                   |
| Default Value       | <code>-1</code> (signifies autoscaling; do not assign this literal value) |

The maximum number of rows in the `prepared_statements_instances` table. If this maximum is exceeded such that a prepared statement cannot be instrumented, the Performance Schema increments the `Performance_schema_prepared_statements_lost` status variable. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

The default value of this variable is autosized based on the value of the `max_prepared_stmt_count` system variable.

- `performance_schema_max_rwlock_classes`

|                          |                                                        |
|--------------------------|--------------------------------------------------------|
| Command-Line Format      | <code>--performance-schema-max-rwlock-classes=#</code> |
| System Variable          | <code>performance_schema_max_rwlock_classes</code>     |
| Scope                    | Global                                                 |
| Dynamic                  | No                                                     |
| Type                     | Integer                                                |
| Default Value (≥ 5.7.25) | 50                                                     |
| Default Value (≤ 5.7.24) | 40                                                     |
| Minimum Value            | 0                                                      |
| Maximum Value            | 256                                                    |

The maximum number of rwlock instruments. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- `performance_schema_max_program_instances`

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-program-instances=#</code>                 |
| System Variable     | <code>performance_schema_max_program_instances</code>                     |
| Scope               | Global                                                                    |
| Dynamic             | No                                                                        |
| Type                | Integer                                                                   |
| Default Value       | <code>-1</code> (signifies autoscaling; do not assign this literal value) |

The maximum number of stored programs for which the Performance Schema maintains statistics. If this maximum is exceeded, the Performance Schema increments the `Performance_schema_program_lost` status variable. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- `performance_schema_max_rwlock_instances`

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-rwlock-instances=#</code>                  |
| System Variable     | <code>performance_schema_max_rwlock_instances</code>                      |
| Scope               | Global                                                                    |
| Dynamic             | No                                                                        |
| Type                | Integer                                                                   |
| Default Value       | <code>-1</code> (signifies autoscaling; do not assign this literal value) |

The maximum number of instrumented rwlock objects. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- `performance_schema_max_socket_classes`

|                     |                                                        |
|---------------------|--------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-socket-classes=#</code> |
| System Variable     | <code>performance_schema_max_socket_classes</code>     |
| Scope               | Global                                                 |
| Dynamic             | No                                                     |
| Type                | Integer                                                |
| Default Value       | 10                                                     |

|               |     |
|---------------|-----|
| Minimum Value | 0   |
| Maximum Value | 256 |

The maximum number of socket instruments. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- [performance\\_schema\\_max\\_socket\\_instances](#)

|                     |                                                              |

| Scope               | Global                                                       |
| Dynamic             | No                                                           |
| Type                | Integer                                                      |
| Default Value       | -1 (signifies autoscaling; do not assign this literal value) |

The maximum number of instrumented socket objects. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- [performance\\_schema\\_max\\_sql\\_text\\_length](#)

|                     |                                                        |
|---------------------|--------------------------------------------------------|
| Command-Line Format | --performance-schema-max-sql-text-length=#             |
| System Variable     | <a href="#">performance_schema_max_sql_text_length</a> |
| Scope               | Global                                                 |
| Dynamic             | No                                                     |
| Type                | Integer                                                |
| Default Value       | 1024                                                   |
| Minimum Value       | 0                                                      |
| Maximum Value       | 1048576                                                |

The maximum number of bytes used to store SQL statements in the `SQL_TEXT` column of the `events_statements_current`, `events_statements_history`, and `events_statements_history_long` statement event tables. Any bytes in excess of `performance_schema_max_sql_text_length` are discarded and do not appear in the `SQL_TEXT` column. Statements differing only after that many initial bytes are indistinguishable in this column.

Decreasing the `performance_schema_max_sql_text_length` value reduces memory use but causes more statements to become indistinguishable if they differ only at the end. Increasing the value increases memory use but permits longer statements to be distinguished.

- [performance\\_schema\\_max\\_stage\\_classes](#)

|                     |                                                      |
|---------------------|------------------------------------------------------|
| Command-Line Format | --performance-schema-max-stage-classes=#             |
| System Variable     | <a href="#">performance_schema_max_stage_classes</a> |
| Scope               | Global                                               |
| Dynamic             | No                                                   |
| Type                | Integer                                              |
| Default Value       | 150                                                  |
| Minimum Value       | 0                                                    |

|               |     |
|---------------|-----|
| Maximum Value | 256 |
|---------------|-----|

The maximum number of stage instruments. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- [performance\\_schema\\_max\\_statement\\_classes](#)

|                     |                                                             |
|---------------------|-------------------------------------------------------------|
| Command-Line Format | --performance-schema-max-statement-classes=#                |
| System Variable     | <a href="#">performance_schema_max_statement_classes</a>    |
| Scope               | Global                                                      |
| Dynamic             | No                                                          |
| Type                | Integer                                                     |
| Default Value       | -1 (signifies autosizing; do not assign this literal value) |

The maximum number of statement instruments. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

The default value is calculated at server build time based on the number of commands in the client/server protocol and the number of SQL statement types supported by the server.

This variable should not be changed, unless to set it to 0 to disable all statement instrumentation and save all memory associated with it. Setting the variable to nonzero values other than the default has no benefit; in particular, values larger than the default cause more memory to be allocated then is needed.

- [performance\\_schema\\_max\\_statement\\_stack](#)

|                     |                                                        |
|---------------------|--------------------------------------------------------|
| Command-Line Format | --performance-schema-max-statement-stack=#             |
| System Variable     | <a href="#">performance_schema_max_statement_stack</a> |
| Scope               | Global                                                 |
| Dynamic             | No                                                     |
| Type                | Integer                                                |
| Default Value       | 10                                                     |

The maximum depth of nested stored program calls for which the Performance Schema maintains statistics. When this maximum is exceeded, the Performance Schema increments the [Performance\\_schema\\_nested\\_statement\\_lost](#) status variable for each stored program statement executed.

- [performance\\_schema\\_max\\_table\\_handles](#)

|                     |                                                              |
|---------------------|--------------------------------------------------------------|
| Command-Line Format | --performance-schema-max-table-handles=#                     |
| System Variable     | <a href="#">performance_schema_max_table_handles</a>         |
| Scope               | Global                                                       |
| Dynamic             | No                                                           |
| Type                | Integer                                                      |
| Default Value       | -1 (signifies autoscaling; do not assign this literal value) |

The maximum number of opened table objects. This value controls the size of the [table\\_handles](#) table. If this maximum is exceeded such that a table handle cannot be instrumented, the Performance Schema increments the [Performance\\_schema\\_table\\_handles\\_lost](#) status variable. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- `performance_schema_max_table_instances`

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-table-instances=#</code>                   |
| System Variable     | <code>performance_schema_max_table_instances</code>                       |
| Scope               | Global                                                                    |
| Dynamic             | No                                                                        |
| Type                | Integer                                                                   |
| Default Value       | <code>-1</code> (signifies autoscaling; do not assign this literal value) |

The maximum number of instrumented table objects. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- `performance_schema_max_table_lock_stat`

|                     |                                                                          |
|---------------------|--------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-table-lock-stat=#</code>                  |
| System Variable     | <code>performance_schema_max_table_lock_stat</code>                      |
| Scope               | Global                                                                   |
| Dynamic             | No                                                                       |
| Type                | Integer                                                                  |
| Default Value       | <code>-1</code> (signifies autosizing; do not assign this literal value) |

The maximum number of tables for which the Performance Schema maintains lock statistics. If this maximum is exceeded such that table lock statistics are lost, the Performance Schema increments the `Performance_schema_table_lock_stat_lost` status variable.

- `performance_schema_max_thread_classes`

|                     |                                                        |
|---------------------|--------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-thread-classes=#</code> |
| System Variable     | <code>performance_schema_max_thread_classes</code>     |
| Scope               | Global                                                 |
| Dynamic             | No                                                     |
| Type                | Integer                                                |
| Default Value       | <code>50</code>                                        |
| Minimum Value       | <code>0</code>                                         |
| Maximum Value       | <code>256</code>                                       |

The maximum number of thread instruments. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

- `performance_schema_max_thread_instances`

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-max-thread-instances=#</code>                  |
| System Variable     | <code>performance_schema_max_thread_instances</code>                      |
| Scope               | Global                                                                    |
| Dynamic             | No                                                                        |
| Type                | Integer                                                                   |
| Default Value       | <code>-1</code> (signifies autoscaling; do not assign this literal value) |

Schema increments the `Performance_schema_thread_instances_lost` status variable. For information about how to set and use this variable, see [Section 25.7, “Performance Schema Status Monitoring”](#).

The `max_connections` system variable affects how many threads can run in the server. `performance_schema_max_thread_instances` affects how many of these running threads can be instrumented.

The `variables_by_thread` and `status_by_thread` tables contain system and status variable information only about foreground threads. If not all threads are instrumented by the Performance Schema, this table may miss some rows. In this case, the `Performance_schema_thread_instances_lost` status variable is greater than zero.

- `performance_schema_session_connect_attrs_size`

|                     |                                                                          |
|---------------------|--------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-session-connect-attrs-size=#</code>           |
| System Variable     | <code>performance_schema_session_connect_attrs_size</code>               |
| Scope               | Global                                                                   |
| Dynamic             | No                                                                       |
| Type                | Integer                                                                  |
| Default Value       | <code>-1</code> (signifies autosizing; do not assign this literal value) |
| Minimum Value       | <code>-1</code>                                                          |
| Maximum Value       | <code>1048576</code>                                                     |

The amount of preallocated memory per thread reserved to hold connection attribute key-value pairs. If the aggregate size of connection attribute data sent by a client is larger than this amount, the Performance Schema truncates the attribute data, increments the `Performance_schema_session_connect_attrs_lost` status variable, and writes a message to the error log indicating that truncation occurred if the `log_error_verbosity` system variable value is greater than 1.

The default value of `performance_schema_session_connect_attrs_size` is autosized at server startup. This value may be small, so if truncation occurs (`Performance_schema_session_connect_attrs_lost` becomes nonzero), you may wish to set `performance_schema_session_connect_attrs_size` explicitly to a larger value.

Although the maximum permitted `performance_schema_session_connect_attrs_size` value is 1MB, the effective maximum is 64KB because the server imposes a limit of 64KB on the aggregate size of connection attribute data it can accept. If a client attempts to send more than 64KB of attribute data, the server rejects the connection. For more information, see [Section 25.12.9, “Performance Schema Connection Attribute Tables”](#).

- `performance_schema_setup_actors_size`

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-setup-actors-size=#</code>                     |
| System Variable     | <code>performance_schema_setup_actors_size</code>                         |
| Scope               | Global                                                                    |
| Dynamic             | No                                                                        |
| Type                | Integer                                                                   |
| Default Value       | <code>-1</code> (signifies autoscaling; do not assign this literal value) |

The number of rows in the `setup_actors` table.

- `performance_schema_setup_objects_size`

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-setup-objects-size=#</code>                    |
| System Variable     | <code>performance_schema_setup_objects_size</code>                        |
| Scope               | Global                                                                    |
| Dynamic             | No                                                                        |
| Type                | Integer                                                                   |
| Default Value       | <code>-1</code> (signifies autoscaling; do not assign this literal value) |

The number of rows in the `setup_objects` table.

- `performance_schema_users_size`

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| Command-Line Format | <code>--performance-schema-users-size=#</code>                            |
| System Variable     | <code>performance_schema_users_size</code>                                |
| Scope               | Global                                                                    |
| Dynamic             | No                                                                        |
| Type                | Integer                                                                   |
| Default Value       | <code>-1</code> (signifies autoscaling; do not assign this literal value) |
| Minimum Value       | <code>-1</code> (signifies autoscaling; do not assign this literal value) |
| Maximum Value       | <code>1048576</code>                                                      |

The number of rows in the `users` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `users` table or status variable information in the `status_by_user` table.

## 25.16 Performance Schema Status Variables

The Performance Schema implements several status variables that provide information about instrumentation that could not be loaded or created due to memory constraints:

```
mysql> SHOW STATUS LIKE 'perf%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Performance_schema_accounts_lost | 0 |
| Performance_schema_cond_classes_lost | 0 |
| Performance_schema_cond_instances_lost| 0 |
| Performance_schema_file_classes_lost | 0 |
| Performance_schema_file_handles_lost | 0 |
| Performance_schema_file_instances_lost| 0 |
| Performance_schema_hosts_lost | 0 |
| Performance_schema_locker_lost | 0 |
| Performance_schema_mutex_classes_lost| 0 |
| Performance_schema_mutex_instances_lost| 0 |
| Performance_schema_rwlock_classes_lost| 0 |
| Performance_schema_rwlock_instances_lost| 0 |
| Performance_schema_stage_classes_lost | 0 |
| Performance_schema_statement_classes_lost| 0 |
| Performance_schema_table_handles_lost | 0 |
| Performance_schema_table_instances_lost| 0 |
| Performance_schema_thread_classes_lost| 0 |
| Performance_schema_thread_instances_lost| 0 |
| Performance_schema_users_lost | 0 |
+-----+-----+
```

For information on using these variables to check Performance Schema status, see [Section 25.7, “Performance Schema Status Monitoring”](#).

Performance Schema status variables have the following meanings:

- [Performance\\_schema\\_accounts\\_lost](#)

The number of times a row could not be added to the `accounts` table because it was full.

- [Performance\\_schema\\_cond\\_classes\\_lost](#)

How many condition instruments could not be loaded.

- [Performance\\_schema\\_cond\\_instances\\_lost](#)

How many condition instrument instances could not be created.

- [Performance\\_schema\\_digest\\_lost](#)

The number of digest instances that could not be instrumented in the `events_statements_summary_by_digest` table. This can be nonzero if the value of `performance_schema_digests_size` is too small.

- [Performance\\_schema\\_file\\_classes\\_lost](#)

How many file instruments could not be loaded.

- [Performance\\_schema\\_file\\_handles\\_lost](#)

How many file instrument instances could not be opened.

- [Performance\\_schema\\_file\\_instances\\_lost](#)

How many file instrument instances could not be created.

- [Performance\\_schema\\_hosts\\_lost](#)

The number of times a row could not be added to the `hosts` table because it was full.

- [Performance\\_schema\\_index\\_stat\\_lost](#)

The number of indexes for which statistics were lost. This can be nonzero if the value of `performance_schema_max_index_stat` is too small.

- [Performance\\_schema\\_locker\\_lost](#)

How many events are “lost” or not recorded, due to the following conditions:

- Events are recursive (for example, waiting for A caused a wait on B, which caused a wait on C).
- The depth of the nested events stack is greater than the limit imposed by the implementation.

Events recorded by the Performance Schema are not recursive, so this variable should always be 0.

- [Performance\\_schema\\_memory\\_classes\\_lost](#)

The number of times a memory instrument could not be loaded.

- [Performance\\_schema\\_metadata\\_lock\\_lost](#)

The number of metadata locks that could not be instrumented in the `metadata_locks` table. This can be nonzero if the value of `performance_schema_max_metadata_locks` is too small.

- [Performance\\_schema\\_mutex\\_classes\\_lost](#)

How many mutex instruments could not be loaded.

- [Performance\\_schema\\_mutex\\_instances\\_lost](#)

How many mutex instrument instances could not be created.

- [Performance\\_schema\\_nested\\_statement\\_lost](#)

The number of stored program statements for which statistics were lost. This can be nonzero if the value of [performance\\_schema\\_max\\_statement\\_stack](#) is too small.

- [Performance\\_schema\\_prepared\\_statements\\_lost](#)

The number of prepared statements that could not be instrumented in the [prepared\\_statements\\_instances](#) table. This can be nonzero if the value of [performance\\_schema\\_max\\_prepared\\_statements\\_instances](#) is too small.

- [Performance\\_schema\\_program\\_lost](#)

The number of stored programs for which statistics were lost. This can be nonzero if the value of [performance\\_schema\\_max\\_program\\_instances](#) is too small.

- [Performance\\_schema\\_rwlock\\_classes\\_lost](#)

How many rwlock instruments could not be loaded.

- [Performance\\_schema\\_rwlock\\_instances\\_lost](#)

How many rwlock instrument instances could not be created.

- [Performance\\_schema\\_session\\_connect\\_attrs\\_lost](#)

The number of connections for which connection attribute truncation has occurred.

For a given connection, if the client sends connection attribute key-value pairs for which the aggregate size is larger than the reserved storage permitted by the value of the [performance\\_schema\\_session\\_connect\\_attrs\\_size](#) system variable, the Performance Schema truncates the attribute data and increments

[Performance\\_schema\\_session\\_connect\\_attrs\\_lost](#). If this value is nonzero, you may wish to set [performance\\_schema\\_session\\_connect\\_attrs\\_size](#) to a larger value.

For more information about connection attributes, see [Section 25.12.9, “Performance Schema Connection Attribute Tables”](#).

- [Performance\\_schema\\_socket\\_classes\\_lost](#)

How many socket instruments could not be loaded.

- [Performance\\_schema\\_socket\\_instances\\_lost](#)

How many socket instrument instances could not be created.

- [Performance\\_schema\\_stage\\_classes\\_lost](#)

How many stage instruments could not be loaded.

- [Performance\\_schema\\_statement\\_classes\\_lost](#)

How many statement instruments could not be loaded.

- [Performance\\_schema\\_table\\_handles\\_lost](#)

How many table instrument instances could not be opened. This can be nonzero if the value of [performance\\_schema\\_max\\_table\\_handles](#) is too small.

- `Performance_schema_table_instances_lost`

How many table instrument instances could not be created.

- `Performance_schema_table_lock_stat_lost`

The number of tables for which lock statistics were lost. This can be nonzero if the value of `performance_schema_max_table_lock_stat` is too small.

- `Performance_schema_thread_classes_lost`

How many thread instruments could not be loaded.

- `Performance_schema_thread_instances_lost`

The number of thread instances that could not be instrumented in the `threads` table. This can be nonzero if the value of `performance_schema_max_thread_instances` is too small.

- `Performance_schema_users_lost`

The number of times a row could not be added to the `users` table because it was full.

## 25.17 The Performance Schema Memory-Allocation Model

The Performance Schema uses this memory allocation model:

- May allocate memory at server startup
- May allocate additional memory during server operation
- Never free memory during server operation (although it might be recycled)
- Free all memory used at shutdown

The result is to relax memory constraints so that the Performance Schema can be used with less configuration, and to decrease the memory footprint so that consumption scales with server load. Memory used depends on the load actually seen, not the load estimated or explicitly configured for.

Several Performance Schema sizing parameters are autoscaled and need not be configured explicitly unless you want to establish an explicit limit on memory allocation:

```
performance_schema_accounts_size
performance_schema_hosts_size
performance_schema_max_cond_instances
performance_schema_max_file_instances
performance_schema_max_index_stat
performance_schema_max_metadata_locks
performance_schema_max_mutex_instances
performance_schema_max_prepared_statements_instances
performance_schema_max_program_instances
performance_schema_max_rwlock_instances
performance_schema_max_socket_instances
performance_schema_max_table_handles
performance_schema_max_table_instances
performance_schema_max_table_lock_stat
performance_schema_max_thread_instances
performance_schema_users_size
```

For an autoscaled parameter, configuration works like this:

- With the value set to -1 (the default), the parameter is autoscaled:
  - The corresponding internal buffer is empty initially and no memory is allocated.
  - As the Performance Schema collects data, memory is allocated in the corresponding buffer. The buffer size is unbounded, and may grow with the load.

- With the value set to 0:
  - The corresponding internal buffer is empty initially and no memory is allocated.
- With the value set to `N` > 0:
  - The corresponding internal buffer is empty initially and no memory is allocated.
  - As the Performance Schema collects data, memory is allocated in the corresponding buffer, until the buffer size reaches `N`.
  - Once the buffer size reaches `N`, no more memory is allocated. Data collected by the Performance Schema for this buffer is lost, and any corresponding “lost instance” counters are incremented.

To see how much memory the Performance Schema is using, check the instruments designed for that purpose. The Performance Schema allocates memory internally and associates each buffer with a dedicated instrument so that memory consumption can be traced to individual buffers. Instruments named with the prefix `memory/performance_schema/` expose how much memory is allocated for these internal buffers. The buffers are global to the server, so the instruments are displayed only in the `memory_summary_global_by_event_name` table, and not in other `memory_summary_by_xxx_by_event_name` tables.

This query shows the information associated with the memory instruments:

```
SELECT * FROM performance_schema.memory_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'memory/performance_schema/%';
```

## 25.18 Performance Schema and Plugins

Removing a plugin with `UNINSTALL PLUGIN` does not affect information already collected for code in that plugin. Time spent executing the code while the plugin was loaded was still spent even if the plugin is unloaded later. The associated event information, including aggregate information, remains readable in `performance_schema` database tables. For additional information about the effect of plugin installation and removal, see [Section 25.7, “Performance Schema Status Monitoring”](#).

A plugin implementor who instruments plugin code should document its instrumentation characteristics to enable those who load the plugin to account for its requirements. For example, a third-party storage engine should include in its documentation how much memory the engine needs for mutex and other instruments.

## 25.19 Using the Performance Schema to Diagnose Problems

The Performance Schema is a tool to help a DBA do performance tuning by taking real measurements instead of “wild guesses.” This section demonstrates some ways to use the Performance Schema for this purpose. The discussion here relies on the use of event filtering, which is described in [Section 25.4.2, “Performance Schema Event Filtering”](#).

The following example provides one methodology that you can use to analyze a repeatable problem, such as investigating a performance bottleneck. To begin, you should have a repeatable use case where performance is deemed “too slow” and needs optimization, and you should enable all instrumentation (no pre-filtering at all).

1. Run the use case.
2. Using the Performance Schema tables, analyze the root cause of the performance problem. This analysis relies heavily on post-filtering.
3. For problem areas that are ruled out, disable the corresponding instruments. For example, if analysis shows that the issue is not related to file I/O in a particular storage engine, disable the file I/O instruments for that engine. Then truncate the history and summary tables to remove previously collected events.

4. Repeat the process at step 1.

At each iteration, the Performance Schema output, particularly the `events_waits_history_long` table, contains less and less “noise” caused by nonsignificant instruments, and given that this table has a fixed size, contains more and more data relevant to the analysis of the problem at hand.

At each iteration, investigation should lead closer and closer to the root cause of the problem, as the signal-to-noise ratio improves, making analysis easier.

5. Once a root cause of performance bottleneck is identified, take the appropriate corrective action, such as:

- Tune the server parameters (cache sizes, memory, and so forth).
- Tune a query by writing it differently,
- Tune the database schema (tables, indexes, and so forth).
- Tune the code (this applies to storage engine or server developers only).

6. Start again at step 1, to see the effects of the changes on performance.

The `mutex_instances.LOCKED_BY_THREAD_ID` and `rwlock_instances.WRITE_LOCKED_BY_THREAD_ID` columns are extremely important for investigating performance bottlenecks or deadlocks. This is made possible by Performance Schema instrumentation as follows:

1. Suppose that thread 1 is stuck waiting for a mutex.

2. You can determine what the thread is waiting for:

```
SELECT * FROM performance_schema.events_waits_current
WHERE THREAD_ID = thread_1
```

Say the query result identifies that the thread is waiting for mutex A, found in `events_waits_current.OBJECT_INSTANCE_BEGIN`.

3. You can determine which thread is holding mutex A:

```
SELECT * FROM performance_schema.mutex_instances
WHERE OBJECT_INSTANCE_BEGIN = mutex_A;
```

Say the query result identifies that it is thread 2 holding mutex A, as found in `mutex_instances.LOCKED_BY_THREAD_ID`.

4. You can see what thread 2 is doing:

```
SELECT * FROM performance_schema.events_waits_current
WHERE THREAD_ID = thread_2;
```

## 25.19.1 Query Profiling Using Performance Schema

The following example demonstrates how to use Performance Schema statement events and stage events to retrieve data comparable to profiling information provided by `SHOW PROFILES` and `SHOW PROFILE` statements.

The `setup_actors` table can be used to limit the collection of historical events by host, user, or account to reduce runtime overhead and the amount of data collected in history tables. The first step of the example shows how to limit collection of historical events to a specific user.

Performance Schema displays event timer information in picoseconds (trillionths of a second) to normalize timing data to a standard unit. In the following example, `TIMER_WAIT` values are divided

by 1000000000000 to show data in units of seconds. Values are also truncated to 6 decimal places to display data in the same format as `SHOW PROFILES` and `SHOW PROFILE` statements.

1. Limit the collection of historical events to the user running the query. By default, `setup_actors` is configured to allow monitoring and historical event collection for all foreground threads:

```
mysql> SELECT * FROM performance_schema.setup_actors;
+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+
| % | % | % | YES | YES |
+-----+-----+-----+-----+
```

Update the default row in the `setup_actors` table to disable historical event collection and monitoring for all foreground threads, and insert a new row that enables monitoring and historical event collection for the user running the query:

```
mysql> UPDATE performance_schema.setup_actors
 SET ENABLED = 'NO', HISTORY = 'NO'
 WHERE HOST = '%' AND USER = '%';

mysql> INSERT INTO performance_schema.setup_actors
 (HOST,USER,ROLE,ENABLED,HISTORY)
 VALUES('localhost','test_user','%','YES','YES');
```

Data in the `setup_actors` table should now appear similar to the following:

```
mysql> SELECT * FROM performance_schema.setup_actors;
+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+
| % | % | % | NO | NO |
| localhost | test_user | % | YES | YES |
+-----+-----+-----+-----+
```

2. Ensure that statement and stage instrumentation is enabled by updating the `setup_instruments` table. Some instruments may already be enabled by default.

```
mysql> UPDATE performance_schema.setup_instruments
 SET ENABLED = 'YES', TIMED = 'YES'
 WHERE NAME LIKE '%statement%';

mysql> UPDATE performance_schema.setup_instruments
 SET ENABLED = 'YES', TIMED = 'YES'
 WHERE NAME LIKE '%stage%';
```

3. Ensure that `events_statements_*` and `events_stages_*` consumers are enabled. Some consumers may already be enabled by default.

```
mysql> UPDATE performance_schema.setup_consumers
 SET ENABLED = 'YES'
 WHERE NAME LIKE '%events_statements_%';

mysql> UPDATE performance_schema.setup_consumers
 SET ENABLED = 'YES'
 WHERE NAME LIKE '%events_stages_%';
```

4. Under the user account you are monitoring, run the statement that you want to profile. For example:

```
mysql> SELECT * FROM employees.employees WHERE emp_no = 10001;
+-----+-----+-----+-----+
| emp_no | birth_date | first_name | last_name | gender | hire_date |
+-----+-----+-----+-----+
| 10001 | 1953-09-02 | Georgi | Facello | M | 1986-06-26 |
+-----+-----+-----+-----+
```

5. Identify the `EVENT_ID` of the statement by querying the `events_statements_history_long` table. This step is similar to running `SHOW PROFILES` to identify the `Query_ID`. The following query produces output similar to `SHOW PROFILES`:

```
mysql> SELECT EVENT_ID, TRUNCATE(TIMER_WAIT/1000000000000,6) as Duration, SQL_TEXT
 FROM performance_schema.events_statements_history_long WHERE SQL_TEXT like '%10001%';
+-----+-----+-----+
| event_id | duration | sql_text
+-----+-----+-----+
| 31 | 0.028310 | SELECT * FROM employees.employees WHERE emp_no = 10001 |
+-----+-----+-----+
```

6. Query the `events_stages_history_long` table to retrieve the statement's stage events. Stages are linked to statements using event nesting. Each stage event record has a `NESTING_EVENT_ID` column that contains the `EVENT_ID` of the parent statement.

```
mysql> SELECT event_name AS Stage, TRUNCATE(TIMER_WAIT/1000000000000,6) AS Duration
 FROM performance_schema.events_stages_history_long WHERE NESTING_EVENT_ID=31;
+-----+-----+
| Stage | Duration |
+-----+-----+
| stage/sql/starting | 0.000080 |
| stage/sql/checking permissions | 0.000005 |
| stage/sql/Opening tables | 0.027759 |
| stage/sql/init | 0.000052 |
| stage/sql/System lock | 0.000009 |
| stage/sql/optimizing | 0.000006 |
| stage/sql/statistics | 0.000082 |
| stage/sql/preparing | 0.000008 |
| stage/sql/executing | 0.000000 |
| stage/sql/Sending data | 0.000017 |
| stage/sql/end | 0.000001 |
| stage/sql/query end | 0.000004 |
| stage/sql/closing tables | 0.000006 |
| stage/sql/freeing items | 0.000272 |
| stage/sql/cleaning up | 0.000001 |
+-----+-----+
```

## 25.20 Migrating to Performance Schema System and Status Variable Tables

The `INFORMATION_SCHEMA` has tables that contain system and status variable information (see [Section 24.3.11, “The INFORMATION\\_SCHEMA GLOBAL\\_VARIABLES and SESSION\\_VARIABLES Tables](#), and [Section 24.3.10, “The INFORMATION\\_SCHEMA GLOBAL\\_STATUS and SESSION\\_STATUS Tables”](#)). The Performance Schema also contains system and status variable tables (see [Section 25.12.13, “Performance Schema System Variable Tables”](#), and [Section 25.12.14, “Performance Schema Status Variable Tables”](#)). The Performance Schema tables are intended to replace the `INFORMATION_SCHEMA` tables, which are deprecated as of MySQL 5.7.6 and are removed in MySQL 8.0.

This section describes the intended migration path away from the `INFORMATION_SCHEMA` system and status variable tables to the corresponding Performance Schema tables. Application developers should use this information as guidance regarding the changes required to access system and status variables in MySQL 5.7.6 and up as the `INFORMATION_SCHEMA` tables become deprecated and eventually are removed.

### MySQL 5.6

In MySQL 5.6, system and status variable information is available from these `SHOW` statements:

```
SHOW VARIABLES
SHOW STATUS
```

And from these `INFORMATION_SCHEMA` tables:

```
INFORMATION_SCHEMA.GLOBAL_VARIABLES
INFORMATION_SCHEMA.SESSION_VARIABLES

INFORMATION_SCHEMA.GLOBAL_STATUS
```

`INFORMATION_SCHEMA.SESSION_STATUS`

## MySQL 5.7

As of MySQL 5.7.6, the Performance Schema includes these tables as new sources of system and status variable information:

```
performance_schema.global_variables
performance_schema.session_variables
performance_schema.variables_by_thread

performance_schema.global_status
performance_schema.session_status
performance_schema.status_by_thread
performance_schema.status_by_account
performance_schema.status_by_host
performance_schema.status_by_user
```

MySQL 5.7.6 also adds a `show_compatibility_56` system variable to control how the server makes system and status variable information available.

When `show_compatibility_56` is `ON`, compatibility with MySQL 5.6 is enabled. The older system and status variable sources (`SHOW` statements, `INFORMATION_SCHEMA` tables) are available with semantics identical to MySQL 5.6. Applications should run as is, with no code changes, and should see the same variable names and values as in MySQL 5.6. Warnings occur under these circumstances:

- A deprecation warning is raised when selecting from the `INFORMATION_SCHEMA` tables.
- In MySQL 5.7.6 and 5.7.7, a deprecation warning is raised when using a `WHERE` clause with the `SHOW` statements. This behavior does not occur as of MySQL 5.7.8.

When `show_compatibility_56` is `OFF`, compatibility with MySQL 5.6 is disabled and several changes result. Applications must be revised as follows to run properly:

- Selecting from the `INFORMATION_SCHEMA` tables produces an error. Applications that access the `INFORMATION_SCHEMA` tables should be revised to use the corresponding Performance Schema tables instead.

Before MySQL 5.7.9, selecting from the `INFORMATION_SCHEMA` tables produces an empty result set plus a deprecation warning. This was not sufficient notice to signal the need to migrate to the corresponding Performance Schema system and status variable tables for the case that `show_compatibility_56=OFF`. Producing an error in MySQL 5.7.9 and higher makes it more evident that an application is operating under conditions that require modification, as well as where the problem lies.

In MySQL 5.7.6 and 5.7.7, the Performance Schema `session_variables` and `session_status` tables do not fully reflect all variable values in effect for the current session; they include no rows for global variables that have no session counterpart. This is corrected in MySQL 5.7.8.

- Output for the `SHOW` statements is produced using the underlying Performance Schema tables. Applications written to use these statements can still use them, but it is best to use MySQL 5.7.8 or higher. In MySQL 5.7.6 and 5.7.7, the results may differ:
  - `SHOW [SESSION] VARIABLES` output does not include global variables that have no session counterpart.
  - Using a `WHERE` clause with the `SHOW` statements produces an error.
- These `Slave_xxx` status variables become unavailable through `SHOW STATUS`:

```
Slave_heartbeat_period
Slave_last_heartbeat
Slave_received_heartbeats
Slave_retried_transactions
```

#### Slave\_running

Applications that use these status variables should be revised to obtain this information using the replication-related Performance Schema tables. For details, see [Effect of show\\_compatibility\\_56 on Slave Status Variables](#).

- The Performance Schema does not collect statistics for `Com_xxx` status variables in the status variable tables. To obtain global and per-session statement execution counts, use the `events_statements_summary_global_by_event_name` and `events_statements_summary_by_thread_by_event_name` tables, respectively.

#### Migration and Privileges

Initially, with the introduction of Performance Schema system and status variable tables in MySQL 5.7.6, access to those tables required the `SELECT` privilege, just as for other Performance Schema tables. However, this had the consequence that when `show_compatibility_56=OFF`, the `SHOW VARIABLES` and `SHOW STATUS` statements also required the `SELECT` privilege: With compatibility disabled, output for those statements was taken from the Performance Schema `global_variables`, `session_variables`, `global_status`, and `session_status` tables.

As of MySQL 5.7.9, those Performance Schema tables are world readable and accessible without the `SELECT` privilege. Consequently, `SHOW VARIABLES` and `SHOW STATUS` do not require privileges on the underlying Performance Schema tables from which their output is produced when `show_compatibility_56=OFF`.

#### Beyond MySQL 5.7

In a MySQL 8.0, the `INFORMATION_SCHEMA` variable tables and the `show_compatibility_56` system variable are removed, and output from the `SHOW` statements is always based on the underlying Performance Schema tables.

Applications that have been revised to work in MySQL 5.7 when `show_compatibility_56=OFF` should work without further changes, except that it is not possible to test or set `show_compatibility_56` because it does not exist.

## 25.21 Restrictions on Performance Schema

The Performance Schema avoids using mutexes to collect or produce data, so there are no guarantees of consistency and results can sometimes be incorrect. Event values in `performance_schema` tables are nondeterministic and nonrepeatable.

If you save event information in another table, you should not assume that the original events are still available later. For example, if you select events from a `performance_schema` table into a temporary table, intending to join that table with the original table later, there might be no matches.

`mysqldump` and `BACKUP DATABASE` ignore tables in the `performance_schema` database.

Tables in the `performance_schema` database cannot be locked with `LOCK TABLES`, except the `setup_xxx` tables.

Tables in the `performance_schema` database cannot be indexed.

Results for queries that refer to tables in the `performance_schema` database are not saved in the query cache.

Tables in the `performance_schema` database are not replicated.

The Performance Schema is not available in `libmysqld`, the embedded server.

The types of timers might vary per platform. The `performance_timers` table shows which event timers are available. If the values in this table for a given timer name are `NULL`, that timer is not supported on your platform.

Instruments that apply to storage engines might not be implemented for all storage engines.  
Instrumentation of each third-party engine is the responsibility of the engine maintainer.

# Chapter 26 MySQL sys Schema

## Table of Contents

|                                                   |      |
|---------------------------------------------------|------|
| 26.1 Prerequisites for Using the sys Schema ..... | 3957 |
| 26.2 Using the sys Schema .....                   | 3958 |
| 26.3 sys Schema Progress Reporting .....          | 3959 |
| 26.4 sys Schema Object Reference .....            | 3960 |
| 26.4.1 sys Schema Object Index .....              | 3960 |
| 26.4.2 sys Schema Tables and Triggers .....       | 3964 |
| 26.4.3 sys Schema Views .....                     | 3966 |
| 26.4.4 sys Schema Stored Procedures .....         | 4006 |
| 26.4.5 sys Schema Stored Functions .....          | 4024 |

MySQL 5.7 includes the `sys` schema, a set of objects that helps DBAs and developers interpret data collected by the Performance Schema. `sys` schema objects can be used for typical tuning and diagnosis use cases. Objects in this schema include:

- Views that summarize Performance Schema data into more easily understandable form.
- Stored procedures that perform operations such as Performance Schema configuration and generating diagnostic reports.
- Stored functions that query Performance Schema configuration and provide formatting services.

For new installations, the `sys` schema is installed by default during data directory initialization if you use `mysqld` with the `--initialize` or `--initialize-insecure` option. You can drop the `sys` schema manually after initialization if it is unneeded.

For upgrades, `mysql_upgrade` installs the `sys` schema if it is not installed, and upgrades it to the current version otherwise. To permit this behavior to be suppressed, `mysql_upgrade` has a `--skip-sys-schema` option.

`mysql_upgrade` returns an error if a `sys` schema exists but has no `version` view, on the assumption that absence of this view indicates a user-created `sys` schema. To upgrade in this case, remove or rename the existing `sys` schema first.

`sys` schema objects have a `DEFINER` of '`mysql.sys`'@'`localhost`'. Use of the dedicated `mysql.sys` account avoids problems that occur if a DBA renames or removes the `root` account.

## 26.1 Prerequisites for Using the sys Schema

Before using the `sys` schema, the prerequisites described in this section must be satisfied.

Because the `sys` schema provides an alternative means of accessing the Performance Schema, the Performance Schema must be enabled for the `sys` schema to work. See [Section 25.3, “Performance Schema Startup Configuration”](#).

For full access to the `sys` schema, a user must have these privileges:

- `SELECT` on all `sys` tables and views
- `EXECUTE` on all `sys` stored procedures and functions
- `INSERT` and `UPDATE` for the `sys_config` table, if changes are to be made to it
- Additional privileges for certain `sys` schema stored procedures and functions, as noted in their descriptions (for example, the `ps_setup_save()` procedure)

It is also necessary to have privileges for the objects underlying the `sys` schema objects:

- `SELECT` on any Performance Schema tables accessed by `sys` schema objects, and `UPDATE` for any tables to be updated using `sys` schema objects
- `PROCESS` for the `INFORMATION_SCHEMA INNODB_BUFFER_PAGE` table

Certain Performance Schema instruments and consumers must be enabled and (for instruments) timed to take full advantage of `sys` schema capabilities:

- All `wait` instruments
- All `stage` instruments
- All `statement` instruments
- `xxx_current` and `xxx_history_long` consumers for all events

You can use the `sys` schema itself to enable all of the additional instruments and consumers:

```
CALL sys.ps_setup_enable_instrument('wait');
CALL sys.ps_setup_enable_instrument('stage');
CALL sys.ps_setup_enable_instrument('statement');
CALL sys.ps_setup_enable_consumer('current');
CALL sys.ps_setup_enable_consumer('history_long');
```

#### Note

For many uses of the `sys` schema, the default Performance Schema is sufficient for data collection. Enabling all the instruments and consumers just mentioned has a performance impact, so it is preferable to enable only the additional configuration you need. Also, remember that if you enable additional configuration, you can easily restore the default configuration like this:

```
CALL sys.ps_setup_reset_to_default(TRUE);
```

## 26.2 Using the sys Schema

You can make the `sys` schema the default schema so that references to its objects need not be qualified with the schema name:

```
mysql> USE sys;
Database changed
mysql> SELECT * FROM version;
+-----+-----+
| sys_version | mysql_version |
+-----+-----+
| 1.5.1 | 5.7.24-debug-log |
+-----+-----+
```

(The `version` view shows the `sys` schema and MySQL server versions.)

To access `sys` schema objects while a different schema is the default (or simply to be explicit), qualify object references with the schema name:

```
mysql> SELECT * FROM sys.version;
+-----+-----+
| sys_version | mysql_version |
+-----+-----+
| 1.5.1 | 5.7.24-debug-log |
+-----+-----+
```

The `sys` schema contains many views that summarize Performance Schema tables in various ways. Most of these views come in pairs, such that one member of the pair has the same name as the other member, plus a `x$` prefix. For example, the `host_summary_by_file_io` view summarizes file I/O grouped by host and displays latencies converted from picoseconds to more readable values (with units);

```
mysql> SELECT * FROM sys.host_summary_by_file_io;
```

| host       | ios   | io_latency |
|------------|-------|------------|
| localhost  | 67570 | 5.38 s     |
| background | 3468  | 4.18 s     |

The `x$host_summary_by_file_io` view summarizes the same data but displays unformatted picosecond latencies:

```
mysql> SELECT * FROM sys.x$host_summary_by_file_io;
+-----+-----+-----+
| host | ios | io_latency |
+-----+-----+-----+
| localhost | 67574 | 5380678125144 |
| background | 3474 | 4758696829416 |
+-----+-----+-----+
```

The view without the `x$` prefix is intended to provide output that is more user friendly and easier for humans to read. The view with the `x$` prefix that displays the same values in raw form is intended more for use with other tools that perform their own processing on the data. For additional information about the differences between non-`x$` and `x$` views, see [Section 26.4.3, “sys Schema Views”](#).

To examine `sys` schema object definitions, use the appropriate `SHOW` statement or `INFORMATION_SCHEMA` query. For example, to examine the definitions of the `session` view and `format_bytes()` function, use these statements:

```
mysql> SHOW CREATE VIEW sys.session;
mysql> SHOW CREATE FUNCTION sys.format_bytes;
```

However, those statements display the definitions in relatively unformatted form. To view object definitions with more readable formatting, access the individual `.sql` files found under the `scripts/sys_schema` in MySQL source distributions. Prior to MySQL 5.7.28, the sources are maintained in a separate distribution available from the `sys` schema development website at <https://github.com/mysql/mysql-sys>.

Neither `mysqldump` nor `mysqlpump` dump the `sys` schema by default. To generate a dump file, name the `sys` schema explicitly on the command line using either of these commands:

```
mysqldump --databases --routines sys > sys_dump.sql
mysqlpump sys > sys_dump.sql
```

To reinstall the schema from the dump file, use this command:

```
mysql < sys_dump.sql
```

## 26.3 sys Schema Progress Reporting

The following `sys` schema views provide progress reporting for long-running transactions:

```
processlist
session
x$processlist
x$session
```

Assuming that the required instruments and consumers are enabled, the `progress` column of these views shows the percentage of work completed for stages that support progress reporting.

Stage progress reporting requires that the `events_stages_current` consumer be enabled, as well as the instruments for which progress information is desired. Instruments for these stages currently support progress reporting:

```
stage/sql/Copying to tmp table
stage/innodb/alter table (end)
stage/innodb/alter table (flush)
stage/innodb/alter table (insert)
stage/innodb/alter table (log apply index)
```

```
stage/innodb/alter table (log apply table)
stage/innodb/alter table (merge sort)
stage/innodb/alter table (read PK and internal sort)
stage/innodb/buffer pool load
```

For stages that do not support estimated and completed work reporting, or if the required instruments or consumers are not enabled, the `progress` column is `NULL`.

## 26.4 sys Schema Object Reference

The `sys` schema includes tables and triggers, views, and stored procedures and functions. The following sections provide details for each of these objects.

### 26.4.1 sys Schema Object Index

The following tables list `sys` schema objects and provide a short description of each one.

**Table 26.1 sys Schema Tables and Triggers**

| Table or Trigger Name                   | Description                                   |
|-----------------------------------------|-----------------------------------------------|
| <code>sys_config</code>                 | <code>sys</code> schema configuration options |
| <code>sys_config_insert_set_user</code> | <code>sys_config</code> insert trigger        |
| <code>sys_config_update_set_user</code> | <code>sys_config</code> update trigger        |

**Table 26.2 sys Schema Views**

| View Name                                                                            | Description                                                    |
|--------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <code>host_summary, x\$host_summary</code>                                           | Statement activity, file I/O, and connections, grouped by host |
| <code>host_summary_by_file_io, x\$host_summary_by_file_io</code>                     | File I/O, grouped by host                                      |
| <code>host_summary_by_file_io_type, x\$host_summary_by_file_io_type</code>           | File I/O, grouped by host and event type                       |
| <code>host_summary_by_stages, x\$host_summary_by_stages</code>                       | Statement stages, grouped by host                              |
| <code>host_summary_by_statement_latency, x\$host_summary_by_statement_latency</code> | Statement statistics, grouped by host                          |
| <code>host_summary_by_statement_type, x\$host_summary_by_statement_type</code>       | Statements executed, grouped by host and statement             |
| <code>innodb_buffer_stats_by_schema, x\$innodb_buffer_stats_by_schema</code>         | InnoDB buffer information, grouped by schema                   |
| <code>innodb_buffer_stats_by_table, x\$innodb_buffer_stats_by_table</code>           | InnoDB buffer information, grouped by schema and table         |
| <code>innodb_lock_waits, x\$innodb_lock_waits</code>                                 | InnoDB lock information                                        |
| <code>io_by_thread_by_latency, x\$io_by_thread_by_latency</code>                     | I/O consumers, grouped by thread                               |
| <code>io_global_by_file_by_bytes, x\$io_global_by_file_by_bytes</code>               | Global I/O consumers, grouped by file and bytes                |
| <code>io_global_by_file_by_latency, x\$io_global_by_file_by_latency</code>           | Global I/O consumers, grouped by file and latency              |
| <code>io_global_by_wait_by_bytes, x\$io_global_by_wait_by_bytes</code>               | Global I/O consumers, grouped by bytes                         |
| <code>io_global_by_wait_by_latency, x\$io_global_by_wait_by_latency</code>           | Global I/O consumers, grouped by latency                       |

| View Name                                                                                                | Description                                                            |
|----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|
| <code>latest_file_io, x\$latest_file_io</code>                                                           | Most recent I/O, grouped by file and thread                            |
| <code>memory_by_host_by_current_bytes, x\$memory_by_host_by_current_bytes</code>                         | Memory use, grouped by host                                            |
| <code>memory_by_thread_by_current_bytes, x\$memory_by_thread_by_current_bytes</code>                     | Memory use, grouped by thread                                          |
| <code>memory_by_user_by_current_bytes, x\$memory_by_user_by_current_bytes</code>                         | Memory use, grouped by user                                            |
| <code>memory_global_by_current_bytes, x\$memory_global_by_current_bytes</code>                           | Memory use, grouped by allocation type                                 |
| <code>memory_global_total, x\$memory_global_total</code>                                                 | Total memory use                                                       |
| <code>metrics</code>                                                                                     | Server metrics                                                         |
| <code>processlist, x\$processlist</code>                                                                 | Processlist information                                                |
| <code>ps_check_lost_instrumentation</code>                                                               | Variables that have lost instruments                                   |
| <code>schema_auto_increment_columns</code>                                                               | <code>AUTO_INCREMENT</code> column information                         |
| <code>schema_index_statistics, x\$schema_index_statistics</code>                                         | Index statistics                                                       |
| <code>schema_object_overview</code>                                                                      | Types of objects within each schema                                    |
| <code>schema_redundant_indexes</code>                                                                    | Duplicate or redundant indexes                                         |
| <code>schema_table_lock_waits, x\$schema_table_lock_waits</code>                                         | Sessions waiting for metadata locks                                    |
| <code>schema_table_statistics, x\$schema_table_statistics</code>                                         | Table statistics                                                       |
| <code>schema_table_statistics_with_buffer, x\$schema_table_statistics_with_buffer</code>                 | Table statistics, including <code>InnoDB</code> buffer pool statistics |
| <code>schema_tables_with_full_table_scans, x\$schema_tables_with_full_table_scans</code>                 | Tables being accessed with full scans                                  |
| <code>schema_unused_indexes</code>                                                                       | Indexes not in active use                                              |
| <code>session, x\$session</code>                                                                         | Processlist information for user sessions                              |
| <code>session_ssl_status</code>                                                                          | Connection SSL information                                             |
| <code>statement_analysis, x\$statement_analysis</code>                                                   | Statement aggregate statistics                                         |
| <code>statements_with_errors_or_warnings, x\$statements_with_errors_or_warnings</code>                   | Statements that have produced errors or warnings                       |
| <code>statements_with_full_table_scans, x\$statements_with_full_table_scans</code>                       | Statements that have done full table scans                             |
| <code>statements_with_runtimes_in_95th_percentile, x\$statements_with_runtimes_in_95th_percentile</code> | Statements with highest average runtime                                |
| <code>statements_with_sorting, x\$statements_with_sorting</code>                                         | Statements that performed sorts                                        |
| <code>statements_with_temp_tables, x\$statements_with_temp_tables</code>                                 | Statements that used temporary tables                                  |
| <code>user_summary, x\$user_summary</code>                                                               | User statement and connection activity                                 |
| <code>user_summary_by_file_io, x\$user_summary_by_file_io</code>                                         | File I/O, grouped by user                                              |

| View Name                                                                                   | Description                                               |
|---------------------------------------------------------------------------------------------|-----------------------------------------------------------|
| <code>user_summary_by_file_io_type, x<br/>\$user_summary_by_file_io_type</code>             | File I/O, grouped by user and event                       |
| <code>user_summary_by_stages, x<br/>\$user_summary_by_stages</code>                         | Stage events, grouped by user                             |
| <code>user_summary_by_statement_latency, x<br/>\$user_summary_by_statement_latency</code>   | Statement statistics, grouped by user                     |
| <code>user_summary_by_statement_type, x<br/>\$user_summary_by_statement_type</code>         | Statements executed, grouped by user and statement        |
| <code>version</code>                                                                        | Current <code>sys</code> schema and MySQL server versions |
| <code>wait_classes_global_by_avg_latency, x<br/>\$wait_classes_global_by_avg_latency</code> | Wait class average latency, grouped by event class        |
| <code>wait_classes_global_by_latency, x<br/>\$wait_classes_global_by_latency</code>         | Wait class total latency, grouped by event class          |
| <code>waits_by_host_by_latency, x<br/>\$waits_by_host_by_latency</code>                     | Wait events, grouped by host and event                    |
| <code>waits_by_user_by_latency, x<br/>\$waits_by_user_by_latency</code>                     | Wait events, grouped by user and event                    |
| <code>waits_global_by_latency, x<br/>\$waits_global_by_latency</code>                       | Wait events, grouped by event                             |
| <code>x\$ps_digest_95th_percentile_by_avg_us</code>                                         | Helper view for 95th-percentile views                     |
| <code>x\$ps_digest_avg_latency_distribution</code>                                          | Helper view for 95th-percentile views                     |
| <code>x\$ps_schema_table_statistics_io</code>                                               | Helper view for table-statistics views                    |
| <code>x\$schema_flattened_keys</code>                                                       | Helper view for <code>schema_redundant_indexes</code>     |

**Table 26.3 sys Schema Stored Procedures**

| Procedure Name                                     | Description                                   |
|----------------------------------------------------|-----------------------------------------------|
| <code>create_synonym_db()</code>                   | Create synonym for schema                     |
| <code>diagnostics()</code>                         | Collect system diagnostic information         |
| <code>execute_prepared_stmt()</code>               | Execute prepared statement                    |
| <code>ps_setup_disable_background_threads()</code> | Disable background thread instrumentation     |
| <code>ps_setup_disable_consumer()</code>           | Disable consumers                             |
| <code>ps_setup_disable_instrument()</code>         | Disable instruments                           |
| <code>ps_setup_disable_thread()</code>             | Disable instrumentation for thread            |
| <code>ps_setup_enable_background_threads()</code>  | Enable background thread instrumentation      |
| <code>ps_setup_enable_consumer()</code>            | Enable consumers                              |
| <code>ps_setup_enable_instrument()</code>          | Enable instruments                            |
| <code>ps_setup_enable_thread()</code>              | Enable instrumentation for thread             |
| <code>ps_setup_reload_saved()</code>               | Reload saved Performance Schema configuration |
| <code>ps_setup_reset_to_default()</code>           | Reset saved Performance Schema configuration  |

| Procedure Name                                    | Description                                         |
|---------------------------------------------------|-----------------------------------------------------|
| <code>ps_setup_save()</code>                      | Save Performance Schema configuration               |
| <code>ps_setup_show_disabled()</code>             | Display disabled Performance Schema configuration   |
| <code>ps_setup_show_disabled_consumers()</code>   | Display disabled Performance Schema consumers       |
| <code>ps_setup_show_disabled_instruments()</code> | Display disabled Performance Schema instruments     |
| <code>ps_setup_show_enabled()</code>              | Display enabled Performance Schema configuration    |
| <code>ps_setup_show_enabled_consumers()</code>    | Display enabled Performance Schema consumers        |
| <code>ps_setup_show_enabled_instruments()</code>  | Display enabled Performance Schema instruments      |
| <code>ps_statement_avg_latency_histogram()</code> | Display statement latency histogram                 |
| <code>ps_trace_statement_digest()</code>          | Trace Performance Schema instrumentation for digest |
| <code>ps_trace_thread()</code>                    | Dump Performance Schema data for thread             |
| <code>ps_truncate_all_tables()</code>             | Truncate Performance Schema summary tables          |
| <code>statement_performance_analyzer()</code>     | Report of statements running on server              |
| <code>table_exists()</code>                       | Whether a table exists                              |

**Table 26.4 sys Schema Stored Functions**

| Function Name                                   | Description                                                              |
|-------------------------------------------------|--------------------------------------------------------------------------|
| <code>extract_schema_from_file_name()</code>    | Extract schema name from file path name                                  |
| <code>extract_table_from_file_name()</code>     | Extract table name from file path name                                   |
| <code>format_bytes()</code>                     | Convert byte count to value with units                                   |
| <code>format_path()</code>                      | Replace data and temp-file directories in path name with symbolic values |
| <code>format_statement()</code>                 | Truncate long statement to fixed length                                  |
| <code>format_time()</code>                      | Convert picoseconds value to value with units                            |
| <code>list_add()</code>                         | Add item to list                                                         |
| <code>list_drop()</code>                        | Remove item from list                                                    |
| <code>ps_is_account_enabled()</code>            | Check whether account instrumentation is enabled                         |
| <code>ps_is_consumer_enabled()</code>           | Check whether consumer is enabled                                        |
| <code>ps_is_instrument_default_enabled()</code> | Check whether instrument is enabled                                      |
| <code>ps_is_instrument_default_timed()</code>   | Check whether instrument is timed                                        |
| <code>ps_is_thread_instrumented()</code>        | Check whether thread is instrumented                                     |
| <code>ps_thread_account()</code>                | Return account for thread ID                                             |
| <code>ps_thread_id()</code>                     | Return thread ID for connection ID                                       |

| Function Name                     | Description                                         |
|-----------------------------------|-----------------------------------------------------|
| <code>ps_thread_stack()</code>    | Return event information for thread ID              |
| <code>ps_thread_trx_info()</code> | Return transaction information for thread ID        |
| <code>quote_identifier()</code>   | Return string as quoted identifier                  |
| <code>sys_get_config()</code>     | Return <code>sys</code> schema configuration option |
| <code>version_major()</code>      | MySQL server major version number                   |
| <code>version_minor()</code>      | MySQL server minor version number                   |
| <code>version_patch()</code>      | MySQL server patch release version number           |

## 26.4.2 sys Schema Tables and Triggers

The following sections describe `sys` schema tables and triggers.

### 26.4.2.1 The `sys_config` Table

This table contains `sys` schema configuration options, one row per option. Configuration changes made by updating this table persist across client sessions and server restarts.

The `sys_config` table has these columns:

- `variable`

The configuration option name.

- `value`

The configuration option value.

- `set_time`

The timestamp of the most recent modification to the row.

- `set_by`

The account that made the most recent modification to the row. The value is `NULL` if the row has not been changed since the `sys` schema was installed.

As an efficiency measure to minimize the number of direct reads from the `sys_config` table, `sys` schema functions that use a value from this table check for a user-defined variable with a corresponding name, which is the user-defined variable having the same name plus a `@sys.` prefix. (For example, the variable corresponding to the `diagnostics.include_raw` option is `@sys.diagnostics.include_raw`.) If the user-defined variable exists in the current session and is non-`NULL`, the function uses its value in preference to the value in the `sys_config` table. Otherwise, the function reads and uses the value from the table. In the latter case, the calling function conventionally also sets the corresponding user-defined variable to the table value so that further references to the configuration option within the same session use the variable and need not read the table again.

For example, the `statement_truncate_len` option controls the maximum length of statements returned by the `format_statement()` function. The default is 64. To temporarily change the value to 32 for your current session, set the corresponding `@sys.statement_truncate_len` user-defined variable:

```
mysql> SET @stmt = 'SELECT variable, value, set_time, set_by FROM sys_config';
mysql> SELECT sys.format_statement(@stmt);
```

```
+-----+
| sys.format_statement(@stmt) |
+-----+
| SELECT variable, value, set_time, set_by FROM sys_config |
+-----+
mysql> SET @sys.statement_truncate_len = 32;
mysql> SELECT sys.format_statement(@stmt);
+-----+
| sys.format_statement(@stmt) |
+-----+
| SELECT variabl ... ROM sys_config |
+-----+
```

Subsequent invocations of `format_statement()` within the session continue to use the user-defined variable value (32), rather than the value stored in the table (64).

To stop using the user-defined variable and revert to using the value in the table, set the variable to `NULL` within your session:

```
mysql> SET @sys.statement_truncate_len = NULL;
mysql> SELECT sys.format_statement(@stmt);
+-----+
| sys.format_statement(@stmt) |
+-----+
| SELECT variable, value, set_time, set_by FROM sys_config |
+-----+
```

Alternatively, end your current session (causing the user-defined variable to no longer exist) and begin a new session.

The conventional relationship just described between options in the `sys_config` table and user-defined variables can be exploited to make temporary configuration changes that end when your session ends. However, if you set a user-defined variable and then subsequently change the corresponding table value within the same session, the changed table value is not used in that session as long as the user-defined variable exists and is not `NULL`. (The changed table value *is* used in other sessions that do not have the user-defined variable assigned.)

The following list describes the options in the `sys_config` table and the corresponding user-defined variables:

- `diagnostics.allow_i_s_tables`, `@sys.diagnostics.allow_i_s_tables`

If this option is `ON`, the `diagnostics()` procedure is permitted to perform table scans on the `INFORMATION_SCHEMA.TABLES` table. This can be expensive if there are many tables. The default is `OFF`.

- `diagnostics.include_raw`, `@sys.diagnostics.include_raw`

If this option is `ON`, the `diagnostics()` procedure includes the raw output from querying the `metrics` view. The default is `OFF`.

- `ps_thread_trx_info.max_length`, `@sys.ps_thread_trx_info.max_length`

The maximum length for JSON output produced by the `ps_thread_trx_info()` function. The default is 65535.

- `statement_performance_analyzer.limit`,  
`@sys.statement_performance_analyzer.limit`

The maximum number of rows to return for views that have no built-in limit. (For example, the `statements_with_runtimes_in_95th_percentile` view has a built-in limit in the sense that it returns only statements with average execution time in the 95th percentile.) The default is 100.

- `statement_performance_analyzer.view`,  
`@sys.statement_performance_analyzer.view`

The custom query or view to be used by the `statement_performance_analyzer()` procedure (which is itself invoked by the `diagnostics()` procedure). If the option value contains a space, it is interpreted as a query. Otherwise, it must be the name of an existing view that queries the Performance Schema `events_statements_summary_by_digest` table. There cannot be any `LIMIT` clause in the query or view definition if the `statement_performance_analyzer.limit` configuration option is greater than 0. The default is `NULL` (no custom view defined).

- `statement_truncate_len, @sys.statement_truncate_len`

The maximum length of statements returned by the `format_statement()` function. Longer statements are truncated to this length. The default is 64.

Other options can be added to the `sys_config` table. For example, the `diagnostics()` and `execute_prepared_stmt()` procedures use the `debug` option if it exists, but this option is not part of the `sys_config` table by default because debug output normally is enabled only temporarily, by setting the corresponding `@sys.debug` user-defined variable. To enable debug output without having to set that variable in individual sessions, add the option to the table:

```
mysql> INSERT INTO sys.sys_config (variable, value) VALUES('debug', 'ON');
```

To change the debug setting in the table, do two things. First, modify the value in the table itself:

```
mysql> UPDATE sys.sys_config
 SET value = 'OFF'
 WHERE variable = 'debug';
```

Second, to also ensure that procedure invocations within the current session use the changed value from the table, set the corresponding user-defined variable to `NULL`:

```
mysql> SET @sys.debug = NULL;
```

#### 26.4.2.2 The `sys_config_insert_set_user` Trigger

For rows added to the `sys_config` table by `INSERT` statements, the `sys_config_insert_set_user` trigger sets the `set_by` column to the current user.

#### 26.4.2.3 The `sys_config_update_set_user` Trigger

The `sys_config_update_set_user` trigger for the `sys_config` table is similar to the `sys_config_insert_set_user` trigger, but for `UPDATE` statements.

### 26.4.3 sys Schema Views

The following sections describe `sys` schema views.

The `sys` schema contains many views that summarize Performance Schema tables in various ways. Most of these views come in pairs, such that one member of the pair has the same name as the other member, plus a `x$` prefix. For example, the `host_summary_by_file_io` view summarizes file I/O grouped by host and displays latencies converted from picoseconds to more readable values (with units);

```
mysql> SELECT * FROM sys.host_summary_by_file_io;
+-----+-----+-----+
| host | ios | io_latency |
+-----+-----+-----+
| localhost | 67570 | 5.38 s |
| background | 3468 | 4.18 s |
+-----+-----+-----+
```

The `x$host_summary_by_file_io` view summarizes the same data but displays unformatted picosecond latencies:

```
mysql> SELECT * FROM sys.x$host_summary_by_file_io;
+-----+-----+
| host | ios | io_latency |
+-----+-----+
| localhost | 67574 | 5380678125144 |
| background | 3474 | 4758696829416 |
+-----+-----+
```

The view without the `x$` prefix is intended to provide output that is more user friendly and easier to read. The view with the `x$` prefix that displays the same values in raw form is intended more for use with other tools that perform their own processing on the data.

Views without the `x$` prefix differ from the corresponding `x$` views in these ways:

- Byte counts are formatted with size units using `format_bytes()`.
- Time values are formatted with temporal units using `format_time()`.
- SQL statements are truncated to a maximum display width using `format_statement()`.
- Path name are shortened using `format_path()`.

#### 26.4.3.1 The `host_summary` and `x$host_summary` Views

These views summarize statement activity, file I/O, and connections, grouped by host.

The `host_summary` and `x$host_summary` views have these columns:

- `host`

The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `statements`

The total number of statements for the host.

- `statement_latency`

The total wait time of timed statements for the host.

- `statement_avg_latency`

The average wait time per timed statement for the host.

- `table_scans`

The total number of table scans for the host.

- `file_ios`

The total number of file I/O events for the host.

- `file_io_latency`

The total wait time of timed file I/O events for the host.

- `current_connections`

The current number of connections for the host.

- `total_connections`

The total number of connections for the host.

- `unique_users`

The number of distinct users for the host.

- `current_memory`

The current amount of allocated memory for the host.

- `total_memory_allocated`

The total amount of allocated memory for the host.

#### 26.4.3.2 The `host_summary_by_file_io` and `x$host_summary_by_file_io` Views

These views summarize file I/O, grouped by host. By default, rows are sorted by descending total file I/O latency.

The `host_summary_by_file_io` and `x$host_summary_by_file_io` views have these columns:

- `host`

The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `ios`

The total number of file I/O events for the host.

- `io_latency`

The total wait time of timed file I/O events for the host.

#### 26.4.3.3 The `host_summary_by_file_io_type` and `x$host_summary_by_file_io_type` Views

These views summarize file I/O, grouped by host and event type. By default, rows are sorted by host and descending total I/O latency.

The `host_summary_by_file_io_type` and `x$host_summary_by_file_io_type` views have these columns:

- `host`

The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `event_name`

The file I/O event name.

- `total`

The total number of occurrences of the file I/O event for the host.

- `total_latency`

The total wait time of timed occurrences of the file I/O event for the host.

- `max_latency`

The maximum single wait time of timed occurrences of the file I/O event for the host.

#### 26.4.3.4 The `host_summary_by_stages` and `x$host_summary_by_stages` Views

These views summarize statement stages, grouped by host. By default, rows are sorted by host and descending total latency.

The `host_summary_by_stages` and `x$host_summary_by_stages` views have these columns:

- `host`

The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `event_name`

The stage event name.

- `total`

The total number of occurrences of the stage event for the host.

- `total_latency`

The total wait time of timed occurrences of the stage event for the host.

- `avg_latency`

The average wait time per timed occurrence of the stage event for the host.

#### 26.4.3.5 The `host_summary_by_statement_latency` and `x$host_summary_by_statement_latency` Views

These views summarize overall statement statistics, grouped by host. By default, rows are sorted by descending total latency.

The `host_summary_by_statement_latency` and `x$host_summary_by_statement_latency` views have these columns:

- `host`

The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `total`

The total number of statements for the host.

- `total_latency`

The total wait time of timed statements for the host.

- `max_latency`

The maximum single wait time of timed statements for the host.

- `lock_latency`

The total time waiting for locks by timed statements for the host.

- `rows_sent`

The total number of rows returned by statements for the host.

- `rows_examined`

The total number of rows read from storage engines by statements for the host.

- `rows_affected`

The total number of rows affected by statements for the host.

- `full_scans`

The total number of full table scans by statements for the host.

#### **26.4.3.6 The `host_summary_by_statement_type` and `x$host_summary_by_statement_type` Views**

These views summarize information about statements executed, grouped by host and statement type. By default, rows are sorted by host and descending total latency.

The `host_summary_by_statement_type` and `x$host_summary_by_statement_type` views have these columns:

- `host`

The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `statement`

The final component of the statement event name.

- `total`

The total number of occurrences of the statement event for the host.

- `total_latency`

The total wait time of timed occurrences of the statement event for the host.

- `max_latency`

The maximum single wait time of timed occurrences of the statement event for the host.

- `lock_latency`

The total time waiting for locks by timed occurrences of the statement event for the host.

- `rows_sent`

The total number of rows returned by occurrences of the statement event for the host.

- `rows_examined`

The total number of rows read from storage engines by occurrences of the statement event for the host.

- `rows_affected`

The total number of rows affected by occurrences of the statement event for the host.

- `full_scans`

The total number of full table scans by occurrences of the statement event for the host.

#### 26.4.3.7 The `innodb_buffer_stats_by_schema` and `x$innodb_buffer_stats_by_schema` Views

These views summarize the information in the `INFORMATION_SCHEMA INNODB_BUFFER_PAGE` table, grouped by schema. By default, rows are sorted by descending buffer size.

##### Warning

Querying views that access the `INNODB_BUFFER_PAGE` table can affect performance. Do not query these views on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

The `innodb_buffer_stats_by_schema` and `x$innodb_buffer_stats_by_schema` views have these columns:

- `object_schema`

The schema name for the object, or `InnoDB System` if the table belongs to the `InnoDB` storage engine.

- `allocated`

The total number of bytes allocated for the schema.

- `data`

The total number of data bytes allocated for the schema.

- `pages`

The total number of pages allocated for the schema.

- `pages_hashed`

The total number of hashed pages allocated for the schema.

- `pages_old`

The total number of old pages allocated for the schema.

- `rows_cached`

The total number of cached rows for the schema.

#### 26.4.3.8 The `innodb_buffer_stats_by_table` and `x$innodb_buffer_stats_by_table` Views

These views summarize the information in the `INFORMATION_SCHEMA INNODB_BUFFER_PAGE` table, grouped by schema and table. By default, rows are sorted by descending buffer size.

##### Warning

Querying views that access the `INNODB_BUFFER_PAGE` table can affect performance. Do not query these views on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

The `innodb_buffer_stats_by_table` and `x$innodb_buffer_stats_by_table` views have these columns:

- `object_schema`

The schema name for the object, or `InnoDB System` if the table belongs to the `InnoDB` storage engine.

- `object_name`

The table name.

- `allocated`

The total number of bytes allocated for the table.

- `data`

The number of data bytes allocated for the table.

- `pages`

The total number of pages allocated for the table.

- `pages_hashed`

The number of hashed pages allocated for the table.

- `pages_old`

The number of old pages allocated for the table.

- `rows_cached`

The number of cached rows for the table.

#### 26.4.3.9 The `innodb_lock_waits` and `x$innodb_lock_waits` Views

These views summarize the `InnoDB` locks that transactions are waiting for. By default, rows are sorted by descending lock age.

The `innodb_lock_waits` and `x$innodb_lock_waits` views have these columns:

- `wait_started`

The time at which the lock wait started.

- `wait_age`

How long the lock has been waited for, as a `TIME` value.

- `wait_age_secs`

How long the lock has been waited for, in seconds.

- `locked_table`

The name of the locked table. This column contains combined schema/table name values.

- `locked_index`

The name of the locked index.

- `locked_type`

The type of the waiting lock.

- `waiting trx id`

The ID of the waiting transaction.

- `waiting trx started`

The time at which the waiting transaction started.

- `waiting trx age`

How long the waiting transaction has been waiting, as a `TIME` value.

- `waiting trx rows locked`

The number of rows locked by the waiting transaction.

- `waiting trx rows modified`

The number of rows modified by the waiting transaction.

- `waiting pid`

The processlist ID of the waiting transaction.

- `waiting query`

The statement that is waiting for the lock.

- `waiting lock id`

The ID of the waiting lock.

- `waiting lock mode`

The mode of the waiting lock.

- `blocking trx id`

The ID of the transaction that is blocking the waiting lock.

- `blocking pid`

The processlist ID of the blocking transaction.

- `blocking query`

The statement the blocking transaction is executing. This field reports NULL if the session that issued the blocking query becomes idle. For more information, see [Identifying a Blocking Query After the Issuing Session Becomes Idle](#).

- `blocking lock id`

The ID of the lock that is blocking the waiting lock.

- `blocking lock mode`

The mode of the lock that is blocking the waiting lock.

- `blocking trx started`

The time at which the blocking transaction started.

- `blocking_trx_age`

How long the blocking transaction has been executing, as a `TIME` value.

- `blocking_trx_rows_locked`

The number of rows locked by the blocking transaction.

- `blocking_trx_rows_modified`

The number of rows modified by the blocking transaction.

- `sql_kill_blocking_query`

The `KILL` statement to execute to kill the blocking statement.

- `sql_kill_blocking_connection`

The `KILL` statement to execute to kill the session running the blocking statement.

#### 26.4.3.10 The `io_by_thread_by_latency` and `x$io_by_thread_by_latency` Views

These views summarize I/O consumers to display time waiting for I/O, grouped by thread. By default, rows are sorted by descending total I/O latency.

The `io_by_thread_by_latency` and `x$io_by_thread_by_latency` views have these columns:

- `user`

For foreground threads, the account associated with the thread. For background threads, the thread name.

- `total`

The total number of I/O events for the thread.

- `total_latency`

The total wait time of timed I/O events for the thread.

- `min_latency`

The minimum single wait time of timed I/O events for the thread.

- `avg_latency`

The average wait time per timed I/O event for the thread.

- `max_latency`

The maximum single wait time of timed I/O events for the thread.

- `thread_id`

The thread ID.

- `processlist_id`

For foreground threads, the processlist ID of the thread. For background threads, `NULL`.

#### 26.4.3.11 The `io_global_by_file_by_bytes` and `x$io_global_by_file_by_bytes` Views

These views summarize global I/O consumers to display amount of I/O, grouped by file. By default, rows are sorted by descending total I/O (bytes read and written).

The `io_global_by_file_by_bytes` and `x$io_global_by_file_by_bytes` views have these columns:

- `file`  
The file path name.
- `count_read`  
The total number of read events for the file.
- `total_read`  
The total number of bytes read from the file.
- `avg_read`  
The average number of bytes per read from the file.
- `count_write`  
The total number of write events for the file.
- `total_written`  
The total number of bytes written to the file.
- `avg_write`  
The average number of bytes per write to the file.
- `total`  
The total number of bytes read and written for the file.
- `write_pct`  
The percentage of total bytes of I/O that were writes.

#### 26.4.3.12 The `io_global_by_file_by_latency` and `x$io_global_by_file_by_latency` Views

These views summarize global I/O consumers to display time waiting for I/O, grouped by file. By default, rows are sorted by descending total latency.

The `io_global_by_file_by_latency` and `x$io_global_by_file_by_latency` views have these columns:

- `file`  
The file path name.
- `total`  
The total number of I/O events for the file.
- `total_latency`  
The total wait time of timed I/O events for the file.
- `count_read`  
The total number of read I/O events for the file.
- `read_latency`

The total wait time of timed read I/O events for the file.

- `count_write`

The total number of write I/O events for the file.

- `write_latency`

The total wait time of timed write I/O events for the file.

- `count_misc`

The total number of other I/O events for the file.

- `misc_latency`

The total wait time of timed other I/O events for the file.

#### 26.4.3.13 The `io_global_by_wait_by_bytes` and `x$io_global_by_wait_by_bytes` Views

These views summarize global I/O consumers to display amount of I/O and time waiting for I/O, grouped by event. By default, rows are sorted by descending total I/O (bytes read and written).

The `io_global_by_wait_by_bytes` and `x$io_global_by_wait_by_bytes` views have these columns:

- `event_name`

The I/O event name, with the `wait/io/file/` prefix stripped.

- `total`

The total number of occurrences of the I/O event.

- `total_latency`

The total wait time of timed occurrences of the I/O event.

- `min_latency`

The minimum single wait time of timed occurrences of the I/O event.

- `avg_latency`

The average wait time per timed occurrence of the I/O event.

- `max_latency`

The maximum single wait time of timed occurrences of the I/O event.

- `count_read`

The number of read requests for the I/O event.

- `total_read`

The number of bytes read for the I/O event.

- `avg_read`

The average number of bytes per read for the I/O event.

- `count_write`

The number of write requests for the I/O event.

- `total_written`

The number of bytes written for the I/O event.

- `avg_written`

The average number of bytes per write for the I/O event.

- `total_requested`

The total number of bytes read and written for the I/O event.

#### 26.4.3.14 The `io_global_by_wait_by_latency` and `x$io_global_by_wait_by_latency` Views

These views summarize global I/O consumers to display amount of I/O and time waiting for I/O, grouped by event. By default, rows are sorted by descending total latency.

The `io_global_by_wait_by_latency` and `x$io_global_by_wait_by_latency` views have these columns:

- `event_name`

The I/O event name, with the `wait/io/file/` prefix stripped.

- `total`

The total number of occurrences of the I/O event.

- `total_latency`

The total wait time of timed occurrences of the I/O event.

- `avg_latency`

The average wait time per timed occurrence of the I/O event.

- `max_latency`

The maximum single wait time of timed occurrences of the I/O event.

- `read_latency`

The total wait time of timed read occurrences of the I/O event.

- `write_latency`

The total wait time of timed write occurrences of the I/O event.

- `misc_latency`

The total wait time of timed other occurrences of the I/O event.

- `count_read`

The number of read requests for the I/O event.

- `total_read`

The number of bytes read for the I/O event.

- `avg_read`

The average number of bytes per read for the I/O event.

- `count_write`

The number of write requests for the I/O event.

- `total_written`

The number of bytes written for the I/O event.

- `avg_written`

The average number of bytes per write for the I/O event.

#### 26.4.3.15 The `latest_file_io` and `x$latest_file_io` Views

These views summarize file I/O activity, grouped by file and thread. By default, rows are sorted with most recent I/O first.

The `latest_file_io` and `x$latest_file_io` views have these columns:

- `thread`

For foreground threads, the account associated with the thread (and port number for TCP/IP connections). For background threads, the thread name and thread ID

- `file`

The file path name.

- `latency`

The wait time of the file I/O event.

- `operation`

The type of operation.

- `requested`

The number of data bytes requested for the file I/O event.

#### 26.4.3.16 The `memory_by_host_by_current_bytes` and `x$memory_by_host_by_current_bytes` Views

These views summarize memory use, grouped by host. By default, rows are sorted by descending amount of memory used.

The `memory_by_host_by_current_bytes` and `x$memory_by_host_by_current_bytes` views have these columns:

- `host`

The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `current_count_used`

The current number of allocated memory blocks that have not been freed yet for the host.

- `current_allocated`

The current number of allocated bytes that have not been freed yet for the host.

- `current_avg_alloc`

The current number of allocated bytes per memory block for the host.

- `current_max_alloc`

The largest single current memory allocation in bytes for the host.

- `total_allocated`

The total memory allocation in bytes for the host.

#### **26.4.3.17 The `memory_by_thread_by_current_bytes` and `x$memory_by_thread_by_current_bytes` Views**

These views summarize memory use, grouped by thread. By default, rows are sorted by descending amount of memory used.

The `memory_by_thread_by_current_bytes` and `x$memory_by_thread_by_current_bytes` views have these columns:

- `thread_id`

The thread ID.

- `user`

The thread user or thread name.

- `current_count_used`

The current number of allocated memory blocks that have not been freed yet for the thread.

- `current_allocated`

The current number of allocated bytes that have not been freed yet for the thread.

- `current_avg_alloc`

The current number of allocated bytes per memory block for the thread.

- `current_max_alloc`

The largest single current memory allocation in bytes for the thread.

- `total_allocated`

The total memory allocation in bytes for the thread.

#### **26.4.3.18 The `memory_by_user_by_current_bytes` and `x$memory_by_user_by_current_bytes` Views**

These views summarize memory use, grouped by user. By default, rows are sorted by descending amount of memory used.

The `memory_by_user_by_current_bytes` and `x$memory_by_user_by_current_bytes` views have these columns:

- `user`

The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `current_count_used`

The current number of allocated memory blocks that have not been freed yet for the user.

- `current_allocated`

The current number of allocated bytes that have not been freed yet for the user.

- `current_avg_alloc`

The current number of allocated bytes per memory block for the user.

- `current_max_alloc`

The largest single current memory allocation in bytes for the user.

- `total_allocated`

The total memory allocation in bytes for the user.

#### **26.4.3.19 The `memory_global_by_current_bytes` and `x$memory_global_by_current_bytes` Views**

These views summarize memory use, grouped by allocation type (that is, by event). By default, rows are sorted by descending amount of memory used.

The `memory_global_by_current_bytes` and `x$memory_global_by_current_bytes` views have these columns:

- `event_name`

The memory event name.

- `current_count`

The total number of occurrences of the event.

- `current_alloc`

The current number of allocated bytes that have not been freed yet for the event.

- `current_avg_alloc`

The current number of allocated bytes per memory block for the event.

- `high_count`

The high-water mark for number of memory blocks allocated for the event.

- `high_alloc`

The high-water mark for number of bytes allocated for the event.

- `high_avg_alloc`

The high-water mark for average number of bytes per memory block allocated for the event.

#### **26.4.3.20 The `memory_global_total` and `x$memory_global_total` Views**

These views summarize total memory use within the server.

The `memory_global_total` and `x$memory_global_total` views have these columns:

- `total_allocated`

The total bytes of memory allocated within the server.

#### 26.4.3.21 The metrics View

This view summarizes MySQL server metrics to show variable names, values, types, and whether they are enabled. By default, rows are sorted by variable type and name.

The `metrics` view includes this information:

- Global status variables from the Performance Schema `global_status` table
- InnoDB metrics from the `INFORMATION_SCHEMA INNODB_METRICS` table
- Current and total memory allocation, based on the Performance Schema memory instrumentation
- The current time (human readable and Unix timestamp formats)

There is some duplication of information between the `global_status` and `INNODB_METRICS` tables, which the `metrics` view eliminates.

The `metrics` view has these columns:

- `Variable_name`

The metric name. The metric type determines the source from which the name is taken:

- For global status variables: The `VARIABLE_NAME` column of the `global_status` table
- For InnoDB metrics: The `NAME` column of the `INNODB_METRICS` table
- For other metrics: A view-provided descriptive string

- `Variable_value`

The metric value. The metric type determines the source from which the value is taken:

- For global status variables: The `VARIABLE_VALUE` column of the `global_status` table
- For InnoDB metrics: The `COUNT` column of the `INNODB_METRICS` table
- For memory metrics: The relevant column from the Performance Schema `memory_summary_global_by_event_name` table
- For the current time: The value of `NOW(3)` or `UNIX_TIMESTAMP(NOW(3))`

- `Type`

The metric type:

- For global status variables: `Global Status`
- For InnoDB metrics: `InnoDB Metrics - %`, where `%` is replaced by the value of the `SUBSYSTEM` column of the `INNODB_METRICS` table
- For memory metrics: `Performance Schema`
- For the current time: `System Time`

- **Enabled**

Whether the metric is enabled:

- For global status variables: **YES**
- For InnoDB metrics: **YES** if the `STATUS` column of the `INNODB_METRICS` table is `enabled`, **NO** otherwise
- For memory metrics: **NO**, **YES**, or **PARTIAL** (currently, **PARTIAL** occurs only for memory metrics and indicates that not all `memory/%` instruments are enabled; Performance Schema memory instruments are always enabled)
- For the current time: **YES**

#### 26.4.3.22 The `processlist` and `x$processlist` Views

The MySQL process list indicates the operations currently being performed by the set of threads executing within the server. The `processlist` and `x$processlist` views summarize process information. They provide more complete information than the `SHOW PROCESSLIST` statement and the `INFORMATION_SCHEMA PROCESSLIST` table, and are also nonblocking. By default, rows are sorted by descending process time and descending wait time. For a comparison of process information sources, see [Sources of Process Information](#).

The column descriptions here are brief. For additional information, see the description of the Performance Schema `threads` table at [Section 25.12.16.3, “The threads Table”](#).

The `processlist` and `x$processlist` views have these columns:

- `thd_id`

The thread ID.

- `conn_id`

The connection ID.

- `user`

The thread user or thread name.

- `db`

The default database for the thread, or `NULL` if there is none.

- `command`

For foreground threads, the type of command the thread is executing on behalf of the client, or `Sleep` if the session is idle.

- `state`

An action, event, or state that indicates what the thread is doing.

- `time`

The time in seconds that the thread has been in its current state.

- `current_statement`

The statement the thread is executing, or `NULL` if it is not executing any statement.

- `statement_latency`

How long the statement has been executing.

- `progress`

The percentage of work completed for stages that support progress reporting. See [Section 26.3, “sys Schema Progress Reporting”](#).

- `lock_latency`

The time spent waiting for locks by the current statement.

- `rows_examined`

The number of rows read from storage engines by the current statement.

- `rows_sent`

The number of rows returned by the current statement.

- `rows_affected`

The number of rows affected by the current statement.

- `tmp_tables`

The number of internal in-memory temporary tables created by the current statement.

- `tmp_disk_tables`

The number of internal on-disk temporary tables created by the current statement.

- `full_scan`

The number of full table scans performed by the current statement.

- `last_statement`

The last statement executed by the thread, if there is no currently executing statement or wait.

- `last_statement_latency`

How long the last statement executed.

- `current_memory`

The number of bytes allocated by the thread.

- `last_wait`

The name of the most recent wait event for the thread.

- `last_wait_latency`

The wait time of the most recent wait event for the thread.

- `source`

The source file and line number containing the instrumented code that produced the event.

- `trx_latency`

The wait time of the current transaction for the thread.

- `trx_state`

The state for the current transaction for the thread.

- `trx_autocommit`

Whether autocommit mode was enabled when the current transaction started.

- `pid`

The client process ID.

- `program_name`

The client program name.

#### 26.4.3.23 The `ps_check_lost_instrumentation` View

This view returns information about lost Performance Schema instruments, to indicate whether the Performance Schema is unable to monitor all runtime data.

The `ps_check_lost_instrumentation` view has these columns:

- `variable_name`

The Performance Schema status variable name indicating which type of instrument was lost.

- `variable_value`

The number of instruments lost.

#### 26.4.3.24 The `schema_auto_increment_columns` View

This view indicates which tables have `AUTO_INCREMENT` columns and provides information about those columns, such as the current and maximum column values and the usage ratio (ratio of used to possible values). By default, rows are sorted by descending usage ratio and maximum column value.

Tables in these schemas are excluded from view output: `mysql`, `sys`, `INFORMATION_SCHEMA`, `performance_schema`.

The `schema_auto_increment_columns` view has these columns:

- `table_schema`

The schema that contains the table.

- `table_name`

The table that contains the `AUTO_INCREMENT` column.

- `column_name`

The name of the `AUTO_INCREMENT` column.

- `data_type`

The data type of the column.

- `column_type`

The column type of the column, which is the data type plus possibly other information. For example, for a column with a `bigint(20) unsigned` column type, the data type is just `bigint`.

- `is_signed`

Whether the column type is signed.

- `is_unsigned`

Whether the column type is unsigned.

- `max_value`

The maximum permitted value for the column.

- `auto_increment`

The current `AUTO_INCREMENT` value for the column.

- `auto_increment_ratio`

The ratio of used to permitted values for the column. This indicates how much of the sequence of values is “used up.”

#### 26.4.3.25 The `schema_index_statistics` and `x$schema_index_statistics` Views

These views provide index statistics. By default, rows are sorted by descending total index latency.

The `schema_index_statistics` and `x$schema_index_statistics` views have these columns:

- `table_schema`

The schema that contains the table.

- `table_name`

The table that contains the index.

- `index_name`

The name of the index.

- `rows_selected`

The total number of rows read using the index.

- `select_latency`

The total wait time of timed reads using the index.

- `rows_inserted`

The total number of rows inserted into the index.

- `insert_latency`

The total wait time of timed inserts into the index.

- `rows_updated`

The total number of rows updated in the index.

- `update_latency`

The total wait time of timed updates in the index.

- `rows_deleted`

The total number of rows deleted from the index.

- `delete_latency`

The total wait time of timed deletes from the index.

#### 26.4.3.26 The `schema_object_overview` View

This view summarizes the types of objects within each schema. By default, rows are sorted by schema and object type.

##### Note

For MySQL instances with a large number of objects, this view might take a long time to execute.

The `schema_object_overview` view has these columns:

- `db`

The schema name.

- `object_type`

The object type: `BASE TABLE`, `INDEX (index_type)`, `EVENT`, `FUNCTION`, `PROCEDURE`, `TRIGGER`, `VIEW`.

- `count`

The number of objects in the schema of the given type.

#### 26.4.3.27 The `schema_redundant_indexes` and `x$schema_flattened_keys` Views

The `schema_redundant_indexes` view displays indexes that duplicate other indexes or are made redundant by them. The `x$schema_flattened_keys` view is a helper view for `schema_redundant_indexes`.

In the following column descriptions, the dominant index is the one that makes the redundant index redundant.

The `schema_redundant_indexes` view has these columns:

- `table_schema`

The schema that contains the table.

- `table_name`

The table that contains the index.

- `redundant_index_name`

The name of the redundant index.

- `redundant_index_columns`

The names of the columns in the redundant index.

- `redundant_index_non_unique`

The number of nonunique columns in the redundant index.

- `dominant_index_name`  
The name of the dominant index.
- `dominant_index_columns`  
The names of the columns in the dominant index.
- `dominant_index_non_unique`  
The number of nonunique columns in the dominant index.
- `subpart_exists`  
Whether the index indexes only part of a column.
- `sql_drop_index`  
The statement to execute to drop the redundant index.

The `x$schema_flattened_keys` view has these columns:

- `table_schema`  
The schema that contains the table.
- `table_name`  
The table that contains the index.
- `index_name`  
An index name.
- `non_unique`  
The number of nonunique columns in the index.
- `subpart_exists`  
Whether the index indexes only part of a column.
- `index_columns`  
The name of the columns in the index.

#### 26.4.3.28 The `schema_table_lock_waits` and `x$schema_table_lock_waits` Views

These views display which sessions are blocked waiting on metadata locks, and what is blocking them.

The column descriptions here are brief. For additional information, see the description of the Performance Schema `metadata_locks` table at [Section 25.12.12.1, “The `metadata\_locks` Table”](#).

The `schema_table_lock_waits` and `x$schema_table_lock_waits` views have these columns:

- `object_schema`  
The schema containing the object to be locked.
- `object_name`  
The name of the instrumented object.
- `waiting_thread_id`

The thread ID of the thread that is waiting for the lock.

- `waiting_pid`

The processlist ID of the thread that is waiting for the lock.

- `waiting_account`

The account associated with the session that is waiting for the lock.

- `waiting_lock_type`

The type of the waiting lock.

- `waiting_lock_duration`

How long the waiting lock has been waiting.

- `waiting_query`

The statement that is waiting for the lock.

- `waiting_query_secs`

How long the statement has been waiting, in seconds.

- `waiting_query_rows_affected`

The number of rows affected by the statement.

- `waiting_query_rows_examined`

The number of rows read from storage engines by the statement.

- `blocking_thread_id`

The thread ID of the thread that is blocking the waiting lock.

- `blocking_pid`

The processlist ID of the thread that is blocking the waiting lock.

- `blocking_account`

The account associated with the thread that is blocking the waiting lock.

- `blocking_lock_type`

The type of lock that is blocking the waiting lock.

- `blocking_lock_duration`

How long the blocking lock has been held.

- `sql_kill_blocking_query`

The `KILL` statement to execute to kill the blocking statement.

- `sql_kill_blocking_connection`

The `KILL` statement to execute to kill the session running the blocking statement.

#### 26.4.3.29 The `schema_table_statistics` and `x$schema_table_statistics` Views

These views summarize table statistics. By default, rows are sorted by descending total wait time (tables with most contention first).

These views user a helper view, `x$ps_schema_table_statistics_io`.

The `schema_table_statistics` and `x$schema_table_statistics` views have these columns:

- `table_schema`

The schema that contains the table.

- `table_name`

The table name.

- `total_latency`

The total wait time of timed I/O events for the table.

- `rows_fetched`

The total number of rows read from the table.

- `fetch_latency`

The total wait time of timed read I/O events for the table.

- `rows_inserted`

The total number of rows inserted into the table.

- `insert_latency`

The total wait time of timed insert I/O events for the table.

- `rows_updated`

The total number of rows updated in the table.

- `update_latency`

The total wait time of timed update I/O events for the table.

- `rows_deleted`

The total number of rows deleted from the table.

- `delete_latency`

The total wait time of timed delete I/O events for the table.

- `io_read_requests`

The total number of read requests for the table.

- `io_read`

The total number of bytes read from the table.

- `io_read_latency`

The total wait time of reads from the table.

- `io_write_requests`

The total number of write requests for the table.

- `io_write`

The total number of bytes written to the table.

- `io_write_latency`

The total wait time of writes to the table.

- `io_misc_requests`

The total number of miscellaneous I/O requests for the table.

- `io_misc_latency`

The total wait time of miscellaneous I/O requests for the table.

#### 26.4.3.30 The `schema_table_statistics_with_buffer` and `x$schema_table_statistics_with_buffer` Views

These views summarize table statistics, including InnoDB buffer pool statistics. By default, rows are sorted by descending total wait time (tables with most contention first).

These views user a helper view, `x$ps_schema_table_statistics_io`.

The `schema_table_statistics_with_buffer` and `x$schema_table_statistics_with_buffer` views have these columns:

- `table_schema`

The schema that contains the table.

- `table_name`

The table name.

- `rows_fetched`

The total number of rows read from the table.

- `fetch_latency`

The total wait time of timed read I/O events for the table.

- `rows_inserted`

The total number of rows inserted into the table.

- `insert_latency`

The total wait time of timed insert I/O events for the table.

- `rows_updated`

The total number of rows updated in the table.

- `update_latency`

The total wait time of timed update I/O events for the table.

- `rows_deleted`

The total number of rows deleted from the table.

- `delete_latency`

The total wait time of timed delete I/O events for the table.

- `io_read_requests`

The total number of read requests for the table.

- `io_read`

The total number of bytes read from the table.

- `io_read_latency`

The total wait time of reads from the table.

- `io_write_requests`

The total number of write requests for the table.

- `io_write`

The total number of bytes written to the table.

- `io_write_latency`

The total wait time of writes to the table.

- `io_misc_requests`

The total number of miscellaneous I/O requests for the table.

- `io_misc_latency`

The total wait time of miscellaneous I/O requests for the table.

- `innodb_buffer_allocated`

The total number of `InnoDB` buffer bytes allocated for the table.

- `innodb_buffer_data`

The total number of `InnoDB` data bytes allocated for the table.

- `innodb_buffer_free`

The total number of `InnoDB` nondata bytes allocated for the table (`innodb_buffer_allocated - innodb_buffer_data`).

- `innodb_buffer_pages`

The total number of `InnoDB` pages allocated for the table.

- `innodb_buffer_pages_hashed`

The total number of `InnoDB` hashed pages allocated for the table.

- `innodb_buffer_pages_old`

The total number of `InnoDB` old pages allocated for the table.

- `innodb_buffer_rows_cached`

The total number of `InnoDB` cached rows for the table.

#### 26.4.3.31 The `schema_tables_with_full_table_scans` and `x$schema_tables_with_full_table_scans` Views

These views display which tables are being accessed with full table scans. By default, rows are sorted by descending rows scanned.

The `schema_tables_with_full_table_scans` and `x$schema_tables_with_full_table_scans` views have these columns:

- `object_schema`

The schema name.

- `object_name`

The table name.

- `rows_full_scanned`

The total number of rows scanned by full scans of the table.

- `latency`

The total wait time of full scans of the table.

#### 26.4.3.32 The `schema_unused_indexes` View

These views display indexes for which there are no events, which indicates that they are not being used. By default, rows are sorted by schema and table.

This view is most useful when the server has been up and processing long enough that its workload is representative. Otherwise, presence of an index in this view may not be meaningful.

The `schema_unused_indexes` view has these columns:

- `object_schema`

The schema name.

- `object_name`

The table name.

- `index_name`

The unused index name.

#### 26.4.3.33 The `session` and `x$session` Views

These views are similar to `processlist` and `x$processlist`, but they filter out background processes to display only user sessions. For descriptions of the columns, see [Section 26.4.3.22, “The processlist and x\\$processlist Views”](#).

#### 26.4.3.34 The `session_ssl_status` View

For each connection, this view displays the SSL version, cipher, and count of reused SSL sessions.

The `session_ssl_status` view has these columns:

- `thread_id`  
The thread ID for the connection.
- `ssl_version`  
The version of SSL used for the connection.
- `ssl_cipher`  
The SSL cipher used for the connection.
- `ssl_sessions_reused`  
The number of reused SSL sessions for the connection.

#### 26.4.3.35 The `statement_analysis` and `x$statement_analysis` Views

These views list normalized statements with aggregated statistics. The content mimics the MySQL Enterprise Monitor Query Analysis view. By default, rows are sorted by descending total latency.

The `statement_analysis` and `x$statement_analysis` views have these columns:

- `query`  
The normalized statement string.
- `db`  
The default database for the statement, or `NULL` if there is none.
- `full_scan`  
The total number of full table scans performed by occurrences of the statement.
- `exec_count`  
The total number of times the statement has executed.
- `err_count`  
The total number of errors produced by occurrences of the statement.
- `warn_count`  
The total number of warnings produced by occurrences of the statement.
- `total_latency`  
The total wait time of timed occurrences of the statement.
- `max_latency`  
The maximum single wait time of timed occurrences of the statement.
- `avg_latency`  
The average wait time per timed occurrence of the statement.
- `lock_latency`  
The total time waiting for locks by timed occurrences of the statement.
- `rows_sent`

The total number of rows returned by occurrences of the statement.

- `rows_sent_avg`

The average number of rows returned per occurrence of the statement.

- `rows_examined`

The total number of rows read from storage engines by occurrences of the statement.

- `rows_examined_avg`

The average number of rows read from storage engines per occurrence of the statement.

- `rows_affected`

The total number of rows affected by occurrences of the statement.

- `rows_affected_avg`

The average number of rows affected per occurrence of the statement.

- `tmp_tables`

The total number of internal in-memory temporary tables created by occurrences of the statement.

- `tmp_disk_tables`

The total number of internal on-disk temporary tables created by occurrences of the statement.

- `rows_sorted`

The total number of rows sorted by occurrences of the statement.

- `sort_merge_passes`

The total number of sort merge passes by occurrences of the statement.

- `digest`

The statement digest.

- `first_seen`

The time at which the statement was first seen.

- `last_seen`

The time at which the statement was most recently seen.

#### **26.4.3.36 The `statements_with_errors_or_warnings` and `x$statements_with_errors_or_warnings` Views**

These views display normalized statements that have produced errors or warnings. By default, rows are sorted by descending error and warning counts.

The `statements_with_errors_or_warnings` and `x$statements_with_errors_or_warnings` views have these columns:

- `query`

The normalized statement string.

- `db`  
The default database for the statement, or `NULL` if there is none.
- `exec_count`  
The total number of times the statement has executed.
- `errors`  
The total number of errors produced by occurrences of the statement.
- `error_pct`  
The percentage of statement occurrences that produced errors.
- `warnings`  
The total number of warnings produced by occurrences of the statement.
- `warning_pct`  
The percentage of statement occurrences that produced warnings.
- `first_seen`  
The time at which the statement was first seen.
- `last_seen`  
The time at which the statement was most recently seen.
- `digest`  
The statement digest.

#### **26.4.3.37 The `statements_with_full_table_scans` and `x$statements_with_full_table_scans` Views**

These views display normalized statements that have done full table scans. By default, rows are sorted by descending percentage of time a full scan was done and descending total latency.

The `statements_with_full_table_scans` and `x$statements_with_full_table_scans` views have these columns:

- `query`  
The normalized statement string.
- `db`  
The default database for the statement, or `NULL` if there is none.
- `exec_count`  
The total number of times the statement has executed.
- `total_latency`  
The total wait time of timed statement events for the statement.
- `no_index_used_count`  
The total number of times no index was used to scan the table.

- `no_good_index_used_count`

The total number of times no good index was used to scan the table.

- `no_index_used_pct`

The percentage of the time no index was used to scan the table.

- `rows_sent`

The total number of rows returned from the table.

- `rows_examined`

The total number of rows read from the storage engine for the table.

- `rows_sent_avg`

The average number of rows returned from the table.

- `rows_examined_avg`

The average number of rows read from the storage engine for the table.

- `first_seen`

The time at which the statement was first seen.

- `last_seen`

The time at which the statement was most recently seen.

- `digest`

The statement digest.

#### 26.4.3.38 The `statements_with_runtimes_in_95th_percentile` and `x$statements_with_runtimes_in_95th_percentile` Views

These views list statements with runtimes in the 95th percentile. By default, rows are sorted by descending average latency.

Both views use two helper views, `x$ps_digest_avg_latency_distribution` and `x$ps_digest_95th_percentile_by_avg_us`.

The `statements_with_runtimes_in_95th_percentile` and `x$statements_with_runtimes_in_95th_percentile` views have these columns:

- `query`

The normalized statement string.

- `db`

The default database for the statement, or `NULL` if there is none.

- `full_scan`

The total number of full table scans performed by occurrences of the statement.

- `exec_count`

The total number of times the statement has executed.

- `err_count`

The total number of errors produced by occurrences of the statement.

- `warn_count`

The total number of warnings produced by occurrences of the statement.

- `total_latency`

The total wait time of timed occurrences of the statement.

- `max_latency`

The maximum single wait time of timed occurrences of the statement.

- `avg_latency`

The average wait time per timed occurrence of the statement.

- `rows_sent`

The total number of rows returned by occurrences of the statement.

- `rows_sent_avg`

The average number of rows returned per occurrence of the statement.

- `rows_examined`

The total number of rows read from storage engines by occurrences of the statement.

- `rows_examined_avg`

The average number of rows read from storage engines per occurrence of the statement.

- `first_seen`

The time at which the statement was first seen.

- `last_seen`

The time at which the statement was most recently seen.

- `digest`

The statement digest.

#### 26.4.3.39 The `statements_with_sorting` and `x$statements_with_sorting` Views

These views list normalized statements that have performed sorts. By default, rows are sorted by descending total latency.

The `statements_with_sorting` and `x$statements_with_sorting` views have these columns:

- `query`

The normalized statement string.

- `db`

The default database for the statement, or `NULL` if there is none.

- `exec_count`

The total number of times the statement has executed.

- `total_latency`

The total wait time of timed occurrences of the statement.

- `sort_merge_passes`

The total number of sort merge passes by occurrences of the statement.

- `avg_sort_merges`

The average number of sort merge passes per occurrence of the statement.

- `sorts_using_scans`

The total number of sorts using table scans by occurrences of the statement.

- `sort_using_range`

The total number of sorts using range accesses by occurrences of the statement.

- `rows_sorted`

The total number of rows sorted by occurrences of the statement.

- `avg_rows_sorted`

The average number of rows sorted per occurrence of the statement.

- `first_seen`

The time at which the statement was first seen.

- `last_seen`

The time at which the statement was most recently seen.

- `digest`

The statement digest.

#### 26.4.3.40 The `statements_with_temp_tables` and `x$statements_with_temp_tables` Views

These views list normalized statements that have used temporary tables. By default, rows are sorted by descending number of on-disk temporary tables used and descending number of in-memory temporary tables used.

The `statements_with_temp_tables` and `x$statements_with_temp_tables` views have these columns:

- `query`

The normalized statement string.

- `db`

The default database for the statement, or `NULL` if there is none.

- `exec_count`

The total number of times the statement has executed.

- `total_latency`  
The total wait time of timed occurrences of the statement.
- `memory_tmp_tables`  
The total number of internal in-memory temporary tables created by occurrences of the statement.
- `disk_tmp_tables`  
The total number of internal on-disk temporary tables created by occurrences of the statement.
- `avg_tmp_tables_per_query`  
The average number of internal temporary tables created per occurrence of the statement.
- `tmp_tables_to_disk_pct`  
The percentage of internal in-memory temporary tables that were converted to on-disk tables.
- `first_seen`  
The time at which the statement was first seen.
- `last_seen`  
The time at which the statement was most recently seen.
- `digest`  
The statement digest.

#### 26.4.3.41 The `user_summary` and `x$user_summary` Views

These views summarize statement activity, file I/O, and connections, grouped by user. By default, rows are sorted by descending total latency.

The `user_summary` and `x$user_summary` views have these columns:

- `user`  
The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.
- `statements`  
The total number of statements for the user.
- `statement_latency`  
The total wait time of timed statements for the user.
- `statement_avg_latency`  
The average wait time per timed statement for the user.
- `table_scans`  
The total number of table scans for the user.
- `file_ios`  
The total number of file I/O events for the user.

- `file_io_latency`

The total wait time of timed file I/O events for the user.

- `current_connections`

The current number of connections for the user.

- `total_connections`

The total number of connections for the user.

- `unique_hosts`

The number of distinct hosts from which connections for the user have originated.

- `current_memory`

The current amount of allocated memory for the user.

- `total_memory_allocated`

The total amount of allocated memory for the user.

#### 26.4.3.42 The `user_summary_by_file_io` and `x$user_summary_by_file_io` Views

These views summarize file I/O, grouped by user. By default, rows are sorted by descending total file I/O latency.

The `user_summary_by_file_io` and `x$user_summary_by_file_io` views have these columns:

- `user`

The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `ios`

The total number of file I/O events for the user.

- `io_latency`

The total wait time of timed file I/O events for the user.

#### 26.4.3.43 The `user_summary_by_file_io_type` and `x$user_summary_by_file_io_type` Views

These views summarize file I/O, grouped by user and event type. By default, rows are sorted by user and descending total latency.

The `user_summary_by_file_io_type` and `x$user_summary_by_file_io_type` views have these columns:

- `user`

The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `event_name`

The file I/O event name.

- `total`

The total number of occurrences of the file I/O event for the user.

- `latency`

The total wait time of timed occurrences of the file I/O event for the user.

- `max_latency`

The maximum single wait time of timed occurrences of the file I/O event for the user.

#### 26.4.3.44 The `user_summary_by_stages` and `x$user_summary_by_stages` Views

These views summarize stages, grouped by user. By default, rows are sorted by user and descending total stage latency.

The `user_summary_by_stages` and `x$user_summary_by_stages` views have these columns:

- `user`

The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `event_name`

The stage event name.

- `total`

The total number of occurrences of the stage event for the user.

- `total_latency`

The total wait time of timed occurrences of the stage event for the user.

- `avg_latency`

The average wait time per timed occurrence of the stage event for the user.

#### 26.4.3.45 The `user_summary_by_statement_latency` and `x$user_summary_by_statement_latency` Views

These views summarize overall statement statistics, grouped by user. By default, rows are sorted by descending total latency.

The `user_summary_by_statement_latency` and `x$user_summary_by_statement_latency` views have these columns:

- `user`

The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `total`

The total number of statements for the user.

- `total_latency`

The total wait time of timed statements for the user.

- `max_latency`

The maximum single wait time of timed statements for the user.

- `lock_latency`

The total time waiting for locks by timed statements for the user.

- `rows_sent`

The total number of rows returned by statements for the user.

- `rows_examined`

The total number of rows read from storage engines by statements for the user.

- `rows_affected`

The total number of rows affected by statements for the user.

- `full_scans`

The total number of full table scans by statements for the user.

#### **26.4.3.46 The `user_summary_by_statement_type` and `x$user_summary_by_statement_type` Views**

These views summarize information about statements executed, grouped by user and statement type. By default, rows are sorted by user and descending total latency.

The `user_summary_by_statement_type` and `x$user_summary_by_statement_type` views have these columns:

- `user`

The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `statement`

The final component of the statement event name.

- `total`

The total number of occurrences of the statement event for the user.

- `total_latency`

The total wait time of timed occurrences of the statement event for the user.

- `max_latency`

The maximum single wait time of timed occurrences of the statement event for the user.

- `lock_latency`

The total time waiting for locks by timed occurrences of the statement event for the user.

- `rows_sent`

The total number of rows returned by occurrences of the statement event for the user.

- `rows_examined`

The total number of rows read from storage engines by occurrences of the statement event for the user.

- `rows_affected`

The total number of rows affected by occurrences of the statement event for the user.

- `full_scans`

The total number of full table scans by occurrences of the statement event for the user.

#### 26.4.3.47 The `version` View

This view provides the current `sys` schema and MySQL server versions.

##### Note

As of MySQL 5.7.28, this view is deprecated; expect it to be removed in a future MySQL version. Affected applications should be adjusted to use an alternative instead. For example, use the `VERSION()` function to retrieve the MySQL server version.

The `version` view has these columns:

- `sys_version`  
The `sys` schema version.
- `mysql_version`  
The MySQL server version.

#### 26.4.3.48 The `wait_classes_global_by_avg_latency` and `x$wait_classes_global_by_avg_latency` Views

These views summarize wait class average latencies, grouped by event class. By default, rows are sorted by descending average latency. Idle events are ignored.

An event class is determined by stripping from the event name everything after the first three components. For example, the class for `wait/io/file/sql/slow_log` is `wait/io/file`.

The `wait_classes_global_by_avg_latency` and `x$wait_classes_global_by_avg_latency` views have these columns:

- `event_class`  
The event class.
- `total`  
The total number of occurrences of events in the class.
- `total_latency`  
The total wait time of timed occurrences of events in the class.
- `min_latency`  
The minimum single wait time of timed occurrences of events in the class.
- `avg_latency`

The average wait time per timed occurrence of events in the class.

- `max_latency`

The maximum single wait time of timed occurrences of events in the class.

#### **26.4.3.49 The `wait_classes_global_by_latency` and `x$wait_classes_global_by_latency` Views**

These views summarize wait class total latencies, grouped by event class. By default, rows are sorted by descending total latency. Idle events are ignored.

An event class is determined by stripping from the event name everything after the first three components. For example, the class for `wait/io/file/sql/slow_log` is `wait/io/file`.

The `wait_classes_global_by_latency` and `x$wait_classes_global_by_latency` views have these columns:

- `event_class`

The event class.

- `total`

The total number of occurrences of events in the class.

- `total_latency`

The total wait time of timed occurrences of events in the class.

- `min_latency`

The minimum single wait time of timed occurrences of events in the class.

- `avg_latency`

The average wait time per timed occurrence of events in the class.

- `max_latency`

The maximum single wait time of timed occurrences of events in the class.

#### **26.4.3.50 The `waits_by_host_by_latency` and `x$waits_by_host_by_latency` Views**

These views summarize wait events, grouped by host and event. By default, rows are sorted by host and descending total latency. Idle events are ignored.

The `waits_by_host_by_latency` and `x$waits_by_host_by_latency` views have these columns:

- `host`

The host from which the connection originated.

- `event`

The event name.

- `total`

The total number of occurrences of the event for the host.

- `total_latency`

The total wait time of timed occurrences of the event for the host.

- `avg_latency`

The average wait time per timed occurrence of the event for the host.

- `max_latency`

The maximum single wait time of timed occurrences of the event for the host.

#### 26.4.3.51 The `waits_by_user_by_latency` and `x$waits_by_user_by_latency` Views

These views summarize wait events, grouped by user and event. By default, rows are sorted by user and descending total latency. Idle events are ignored.

The `waits_by_user_by_latency` and `x$waits_by_user_by_latency` views have these columns:

- `user`

The user associated with the connection.

- `event`

The event name.

- `total`

The total number of occurrences of the event for the user.

- `total_latency`

The total wait time of timed occurrences of the event for the user.

- `avg_latency`

The average wait time per timed occurrence of the event for the user.

- `max_latency`

The maximum single wait time of timed occurrences of the event for the user.

#### 26.4.3.52 The `waits_global_by_latency` and `x$waits_global_by_latency` Views

These views summarize wait events, grouped by event. By default, rows are sorted by descending total latency. Idle events are ignored.

The `waits_global_by_latency` and `x$waits_global_by_latency` views have these columns:

- `events`

The event name.

- `total`

The total number of occurrences of the event.

- `total_latency`

The total wait time of timed occurrences of the event.

- `avg_latency`

The average wait time per timed occurrence of the event.

- `max_latency`

The maximum single wait time of timed occurrences of the event.

## 26.4.4 sys Schema Stored Procedures

The following sections describe `sys` schema stored procedures.

### 26.4.4.1 The `create_synonym_db()` Procedure

Given a schema name, this procedure creates a synonym schema containing views that refer to all the tables and views in the original schema. This can be used, for example, to create a shorter name by which to refer to a schema with a long name (such as `info` rather than `INFORMATION_SCHEMA`).

#### Parameters

- `in_db_name` `VARCHAR(64)`: The name of the schema for which to create the synonym.
- `in_synonym` `VARCHAR(64)`: The name to use for the synonym schema. This schema must not already exist.

#### Example

```
mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| information_schema |
| mysql |
| performance_schema |
| sys |
| world |
+-----+
mysql> CALL sys.create_synonym_db('INFORMATION_SCHEMA', 'info');
+-----+
| summary |
+-----+
| Created 63 views in the info database |
+-----+
mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| information_schema |
| info |
| mysql |
| performance_schema |
| sys |
| world |
+-----+
mysql> SHOW FULL TABLES FROM info;
+-----+-----+
| Tables_in_info | Table_type |
+-----+-----+
| character_sets | VIEW |
| collation_character_set_applicability | VIEW |
| collations | VIEW |
| column_privileges | VIEW |
| columns | VIEW |
| ... |

```

### 26.4.4.2 The `diagnostics()` Procedure

Creates a report of the current server status for diagnostic purposes.

This procedure disables binary logging during its execution by manipulating the session value of the `sql_log_bin` system variable. That is a restricted operation, so the procedure requires privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

Data collected for `diagnostics()` includes this information:

- Information from the `metrics` view (see [Section 26.4.3.21, “The metrics View”](#))
- Information from other relevant `sys` schema views, such as the one that determines queries in the 95th percentile
- Information from the `ndbinfo` schema, if the MySQL server is part of NDB Cluster
- Replication status (both source and replica)

Some of the `sys` schema views are calculated as initial (optional), overall, and delta values:

- The initial view is the content of the view at the start of the `diagnostics()` procedure. This output is the same as the start values used for the delta view. The initial view is included if the `diagnostics.include_raw` configuration option is `ON`.
- The overall view is the content of the view at the end of the `diagnostics()` procedure. This output is the same as the end values used for the delta view. The overall view is always included.
- The delta view is the difference from the beginning to the end of procedure execution. The minimum and maximum values are the minimum and maximum values from the end view, respectively. They do not necessarily reflect the minimum and maximum values in the monitored period. Except for the `metrics` view, the delta is calculated only between the first and last outputs.

## Parameters

- `in_max_runtime INT UNSIGNED`: The maximum data collection time in seconds. Use `NULL` to collect data for the default of 60 seconds. Otherwise, use a value greater than 0.
- `in_interval INT UNSIGNED`: The sleep time between data collections in seconds. Use `NULL` to sleep for the default of 30 seconds. Otherwise, use a value greater than 0.
- `in_auto_config ENUM('current', 'medium', 'full')`: The Performance Schema configuration to use. Permitted values are:
  - `current`: Use the current instrument and consumer settings.
  - `medium`: Enable some instruments and consumers.
  - `full`: Enable all instruments and consumers.

### Note

The more instruments and consumers enabled, the more impact on MySQL server performance. Be careful with the `medium` setting and especially the `full` setting, which has a large performance impact.

Use of the `medium` or `full` setting requires the `SUPER` privilege.

If a setting other than `current` is chosen, the current settings are restored at the end of the procedure.

## Configuration Options

`diagnostics()` operation can be modified using the following configuration options or their corresponding user-defined variables (see [Section 26.4.2.1, “The sys\\_config Table”](#)):

- `debug, @sys.debug`

If this option is `ON`, produce debugging output. The default is `OFF`.

- `diagnostics.allow_i_s_tables, @sys.diagnostics.allow_i_s_tables`

If this option is `ON`, the `diagnostics()` procedure is permitted to perform table scans on the `INFORMATION_SCHEMA.TABLES` table. This can be expensive if there are many tables. The default is `OFF`.

- `diagnostics.include_raw, @sys.diagnostics.include_raw`

If this option is `ON`, the `diagnostics()` procedure output includes the raw output from querying the `metrics` view. The default is `OFF`.

- `statement_truncate_len, @sys.statement_truncate_len`

The maximum length of statements returned by the `format_statement()` function. Longer statements are truncated to this length. The default is 64.

## Example

Create a diagnostics report that starts an iteration every 30 seconds and runs for at most 120 seconds using the current Performance Schema settings:

```
mysql> CALL sys.diagnostics(120, 30, 'current');
```

To capture the output from the `diagnostics()` procedure in a file as it runs, use the `mysql` client `tee filename` and `notee` commands (see [Section 4.5.1.2, “mysql Client Commands”](#)):

```
mysql> tee diag.out;
mysql> CALL sys.diagnostics(120, 30, 'current');
mysql> note;
```

### 26.4.4.3 The `execute_prepared_stmt()` Procedure

Given an SQL statement as a string, executes it as a prepared statement. The prepared statement is deallocated after execution, so it is not subject to reuse. Thus, this procedure is useful primarily for executing dynamic statements on a one-time basis.

This procedure uses `sys_execute_prepared_stmt` as the prepared statement name. If that statement name exists when the procedure is called, its previous content is destroyed.

## Parameters

- `in_query LONGTEXT CHARACTER SET utf8`: The statement string to execute.

## Configuration Options

`execute_prepared_stmt()` operation can be modified using the following configuration options or their corresponding user-defined variables (see [Section 26.4.2.1, “The sys\\_config Table”](#)):

- `debug, @sys.debug`

If this option is `ON`, produce debugging output. The default is `OFF`.

## Example

```
mysql> CALL sys.execute_prepared_stmt('SELECT COUNT(*) FROM mysql.user');
+-----+
| COUNT(*) |
+-----+
| 15 |
+-----+
```

#### 26.4.4.4 The `ps_setup_disable_background_threads()` Procedure

Disables Performance Schema instrumentation for all background threads. Produces a result set indicating how many background threads were disabled. Already disabled threads do not count.

##### Parameters

None.

##### Example

```
mysql> CALL sys.ps_setup_disable_background_threads();
+-----+
| summary |
+-----+
| Disabled 24 background threads |
+-----+
```

#### 26.4.4.5 The `ps_setup_disable_consumer()` Procedure

Disables Performance Schema consumers with names that contain the argument. Produces a result set indicating how many consumers were disabled. Already disabled consumers do not count.

##### Parameters

- `consumer VARCHAR(128)`: The value used to match consumer names, which are identified by using `%consumer%` as an operand for a `LIKE` pattern match.

A value of '' matches all consumers.

##### Example

Disable all statement consumers:

```
mysql> CALL sys.ps_setup_disable_consumer('statement');
+-----+
| summary |
+-----+
| Disabled 4 consumers |
+-----+
```

#### 26.4.4.6 The `ps_setup_disable_instrument()` Procedure

Disables Performance Schema instruments with names that contain the argument. Produces a result set indicating how many instruments were disabled. Already disabled instruments do not count.

##### Parameters

- `in_pattern VARCHAR(128)`: The value used to match instrument names, which are identified by using `%in_pattern%` as an operand for a `LIKE` pattern match.

A value of '' matches all instruments.

##### Example

Disable a specific instrument:

```
mysql> CALL sys.ps_setup_disable_instrument('wait/lock/metadata/sql/mdl');
+-----+
| summary |
+-----+
| Disabled 1 instrument |
+-----+
```

Disable all mutex instruments:

```
mysql> CALL sys.ps_setup_disable_instrument('mutex');
+-----+
| summary |
+-----+
| Disabled 177 instruments |
+-----+
```

#### 26.4.4.7 The ps\_setup\_disable\_thread() Procedure

Given a connection ID, disables Performance Schema instrumentation for the thread. Produces a result set indicating how many threads were disabled. Already disabled threads do not count.

##### Parameters

- `in_connection_id BIGINT`: The connection ID. This is a value of the type given in the `PROCESSLIST_ID` column of the Performance Schema `threads` table or the `Id` column of `SHOW PROCESSLIST` output.

##### Example

Disable a specific connection by its connection ID:

```
mysql> CALL sys.ps_setup_disable_thread(225);
+-----+
| summary |
+-----+
| Disabled 1 thread |
+-----+
```

Disable the current connection:

```
mysql> CALL sys.ps_setup_disable_thread(CONNECTION_ID());
+-----+
| summary |
+-----+
| Disabled 1 thread |
+-----+
```

#### 26.4.4.8 The ps\_setup\_enable\_background\_threads() Procedure

Enables Performance Schema instrumentation for all background threads. Produces a result set indicating how many background threads were enabled. Already enabled threads do not count.

##### Parameters

None.

##### Example

```
mysql> CALL sys.ps_setup_enable_background_threads();
+-----+
| summary |
+-----+
| Enabled 24 background threads |
+-----+
```

#### 26.4.4.9 The ps\_setup\_enable\_consumer() Procedure

Enables Performance Schema consumers with names that contain the argument. Produces a result set indicating how many consumers were enabled. Already enabled consumers do not count.

##### Parameters

- `consumer VARCHAR(128)`: The value used to match consumer names, which are identified by using `%consumer%` as an operand for a `LIKE` pattern match.

A value of '' matches all consumers.

## Example

Enable all statement consumers:

```
mysql> CALL sys.ps_setup_enable_consumer('statement');
+-----+
| summary |
+-----+
| Enabled 4 consumers |
+-----+
```

### 26.4.4.10 The ps\_setup\_enable\_instrument() Procedure

Enables Performance Schema instruments with names that contain the argument. Produces a result set indicating how many instruments were enabled. Already enabled instruments do not count.

## Parameters

- `in_pattern` `VARCHAR(128)`: The value used to match instrument names, which are identified by using `%in_pattern%` as an operand for a `LIKE` pattern match.

A value of '' matches all instruments.

## Example

Enable a specific instrument:

```
mysql> CALL sys.ps_setup_enable_instrument('wait/lock/metadata/sql/mdl');
+-----+
| summary |
+-----+
| Enabled 1 instrument |
+-----+
```

Enable all mutex instruments:

```
mysql> CALL sys.ps_setup_enable_instrument('mutex');
+-----+
| summary |
+-----+
| Enabled 177 instruments |
+-----+
```

### 26.4.4.11 The ps\_setup\_enable\_thread() Procedure

Given a connection ID, enables Performance Schema instrumentation for the thread. Produces a result set indicating how many threads were enabled. Already enabled threads do not count.

## Parameters

- `in_connection_id` `BIGINT`: The connection ID. This is a value of the type given in the `PROCESSLIST_ID` column of the Performance Schema `threads` table or the `Id` column of `SHOW PROCESSLIST` output.

## Example

Enable a specific connection by its connection ID:

```
mysql> CALL sys.ps_setup_enable_thread(225);
+-----+
| summary |
+-----+
| Enabled 1 thread |
+-----+
```

```
+-----+
```

Enable the current connection:

```
mysql> CALL sys.ps_setup_enable_thread(CONNECTION_ID());
+-----+
| summary |
+-----+
| Enabled 1 thread |
+-----+
```

#### 26.4.4.12 The ps\_setup\_reload\_saved() Procedure

Reloads a Performance Schema configuration saved earlier within the same session using `ps_setup_save()`. For more information, see the description of `ps_setup_save()`.

This procedure disables binary logging during its execution by manipulating the session value of the `sql_log_bin` system variable. That is a restricted operation, so the procedure requires privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

##### Parameters

None.

#### 26.4.4.13 The ps\_setup\_reset\_to\_default() Procedure

Resets the Performance Schema configuration to its default settings.

##### Parameters

- `in_verbose BOOLEAN`: Whether to display information about each setup stage during procedure execution. This includes the SQL statements executed.

##### Example

```
mysql> CALL sys.ps_setup_reset_to_default(TRUE)\G
***** 1. row *****
status: Resetting: setup_actors
DELETE
FROM performance_schema.setup_actors
WHERE NOT (HOST = '%' AND USER = '%' AND ROLE = '%')

***** 1. row *****
status: Resetting: setup_actors
INSERT IGNORE INTO performance_schema.setup_actors
VALUES ('%', '%', '%')
...
```

#### 26.4.4.14 The ps\_setup\_save() Procedure

Saves the current Performance Schema configuration. This enables you to alter the configuration temporarily for debugging or other purposes, then restore it to the previous state by invoking the `ps_setup_reload_saved()` procedure.

To prevent other simultaneous calls to save the configuration, `ps_setup_save()` acquires an advisory lock named `sys.ps_setup_save` by calling the `GET_LOCK()` function. `ps_setup_save()` takes a timeout parameter to indicate how many seconds to wait if the lock already exists (which indicates that some other session has a saved configuration outstanding). If the timeout expires without obtaining the lock, `ps_setup_save()` fails.

It is intended you call `ps_setup_reload_saved()` later within the *same* session as `ps_setup_save()` because the configuration is saved in `TEMPORARY` tables. `ps_setup_save()` drops the temporary tables and releases the lock. If you end your session without invoking `ps_setup_save()`, the tables and lock disappear automatically.

This procedure disables binary logging during its execution by manipulating the session value of the `sql_log_bin` system variable. That is a restricted operation, so the procedure requires privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

## Parameters

- `in_timeout INT`: How many seconds to wait to obtain the `sys.ps_setup_save` lock. A negative timeout value means infinite timeout.

## Example

```
mysql> CALL sys.ps_setup_save(10);
... make Performance Schema configuration changes ...
mysql> CALL sys.ps_setup_reload_saved();
```

### 26.4.4.15 The `ps_setup_show_disabled()` Procedure

Displays all currently disabled Performance Schema configuration.

## Parameters

- `in_show_instruments BOOLEAN`: Whether to display disabled instruments. This might be a long list.
- `in_show_threads BOOLEAN`: Whether to display disabled threads.

## Example

```
mysql> CALL sys.ps_setup_show_disabled(TRUE, TRUE);
+-----+
| performance_schema_enabled |
+-----+
| 1 |
+-----+

+-----+
| enabled_users |
+-----+
| '%'@'%' |
+-----+

+-----+-----+-----+-----+
| object_type | objects | enabled | timed |
+-----+-----+-----+-----+
| EVENT | mysql.% | NO | NO |
| EVENT | performance_schema.% | NO | NO |
| EVENT | information_schema.% | NO | NO |
| FUNCTION | mysql.% | NO | NO |
| FUNCTION | performance_schema.% | NO | NO |
| FUNCTION | information_schema.% | NO | NO |
| PROCEDURE | mysql.% | NO | NO |
| PROCEDURE | performance_schema.% | NO | NO |
| PROCEDURE | information_schema.% | NO | NO |
| TABLE | mysql.% | NO | NO |
| TABLE | performance_schema.% | NO | NO |
| TABLE | information_schema.% | NO | NO |
| TRIGGER | mysql.% | NO | NO |
| TRIGGER | performance_schema.% | NO | NO |
| TRIGGER | information_schema.% | NO | NO |
+-----+-----+-----+-----+
...
...
```

### 26.4.4.16 The `ps_setup_show_disabled_consumers()` Procedure

Displays all currently disabled Performance Schema consumers.

## Parameters

None.

## Example

```
mysql> CALL sys.ps_setup_show_disabled_consumers();
+-----+
| disabled_consumers |
+-----+
| events_stages_current |
| events_stages_history |
| events_stages_history_long |
| events_statements_history |
| events_statements_history_long |
| events_transactions_history |
| events_transactions_history_long |
| events_waits_current |
| events_waits_history |
| events_waits_history_long |
+-----+
```

### 26.4.4.17 The ps\_setup\_show\_disabled\_instruments() Procedure

Displays all currently disabled Performance Schema instruments. This might be a long list.

## Parameters

None.

## Example

```
mysql> CALL sys.ps_setup_show_disabled_instruments()\G
***** 1. row *****
disabled_instruments: wait/synch/mutex/sql/TC_LOG_MMAP::LOCK_tc
 timed: NO
***** 2. row *****
disabled_instruments: wait/synch/mutex/sql/THD::LOCK_query_plan
 timed: NO
***** 3. row *****
disabled_instruments: wait/synch/mutex/sql/MYSQL_BIN_LOG::LOCK_commit
 timed: NO
...
...
```

### 26.4.4.18 The ps\_setup\_show\_enabled() Procedure

Displays all currently enabled Performance Schema configuration.

## Parameters

- `in_show_instruments BOOLEAN`: Whether to display enabled instruments. This might be a long list.
- `in_show_threads BOOLEAN`: Whether to display enabled threads.

## Example

```
mysql> CALL sys.ps_setup_show_enabled(FALSE, FALSE);
+-----+
| performance_schema_enabled |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

+-----+
| enabled_users |
```

```
+-----+
| '%'@'%' |
+-----+
1 row in set (0.00 sec)

+-----+-----+-----+-----+
| object_type | objects | enabled | timed |
+-----+-----+-----+-----+
| EVENT | %.% | YES | YES |
| FUNCTION | %.% | YES | YES |
| PROCEDURE | %.% | YES | YES |
| TABLE | %.% | YES | YES |
| TRIGGER | %.% | YES | YES |
+-----+-----+-----+-----+
5 rows in set (0.00 sec)

+-----+
| enabled_consumers |
+-----+
| events_statements_current |
| events_statements_history |
| global_instrumentation |
| statements_digest |
| thread_instrumentation |
+-----+
```

#### 26.4.4.19 The ps\_setup\_show\_enabled\_consumers() Procedure

Displays all currently enabled Performance Schema consumers.

##### Parameters

None.

##### Example

```
mysql> CALL sys.ps_setup_show_enabled_consumers();
+-----+
| enabled_consumers |
+-----+
| events_statements_current |
| events_statements_history |
| global_instrumentation |
| statements_digest |
| thread_instrumentation |
+-----+
```

#### 26.4.4.20 The ps\_setup\_show\_enabled\_instruments() Procedure

Displays all currently enabled Performance Schema instruments. This might be a long list.

##### Parameters

None.

##### Example

```
mysql> CALL sys.ps_setup_show_enabled_instruments()\G
***** 1. row *****
enabled_instruments: wait/io/file/sql/map
timed: YES
***** 2. row *****
enabled_instruments: wait/io/file/sql/binlog
timed: YES
***** 3. row *****
enabled_instruments: wait/io/file/sql/binlog_cache
timed: YES
...
```

### 26.4.4.21 The `ps_statement_avg_latency_histogram()` Procedure

Displays a textual histogram graph of the average latency values across all normalized statements tracked within the Performance Schema `events_statements_summary_by_digest` table.

This procedure can be used to display a very high-level picture of the latency distribution of statements running within this MySQL instance.

#### Parameters

None.

#### Example

The histogram output in statement units. For example, `* = 2 units` in the histogram legend means that each `*` character represents 2 statements.

```
mysql> CALL sys.ps_statement_avg_latency_histogram()\G
***** 1. row *****
Performance Schema Statement Digest Average Latency Histogram:

. = 1 unit
* = 2 units
= 3 units

(0 - 66ms) 88 | #####
(66 - 133ms) 14 |
(133 - 199ms) 4 | ...
(199 - 265ms) 5 | **
(265 - 332ms) 1 | .
(332 - 398ms) 0 |
(398 - 464ms) 1 | .
(464 - 531ms) 0 |
(531 - 597ms) 0 |
(597 - 663ms) 0 |
(663 - 730ms) 0 |
(730 - 796ms) 0 |
(796 - 863ms) 0 |
(863 - 929ms) 0 |
(929 - 995ms) 0 |
(995 - 1062ms) 0 |

Total Statements: 114; Buckets: 16; Bucket Size: 66 ms;
```

### 26.4.4.22 The `ps_trace_statement_digest()` Procedure

Traces all Performance Schema instrumentation for a specific statement digest.

If you find a statement of interest within the Performance Schema `events_statements_summary_by_digest` table, specify its `DIGEST` column MD5 value to this procedure and indicate the polling duration and interval. The result is a report of all statistics tracked within Performance Schema for that digest for the interval.

The procedure also attempts to execute `EXPLAIN` for the longest running example of the digest during the interval. This attempt might fail because the Performance Schema truncates long `SQL_TEXT` values. Consequently, `EXPLAIN` fails due to parse errors.

This procedure disables binary logging during its execution by manipulating the session value of the `sql_log_bin` system variable. That is a restricted operation, so the procedure requires privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

#### Parameters

- `in_digest VARCHAR(32)`: The statement digest identifier to analyze.
- `in_runtime INT`: How long to run the analysis in seconds.

- `in_interval DECIMAL(2,2)`: The analysis interval in seconds (which can be fractional) at which to try to take snapshots.
- `in_start_fresh BOOLEAN`: Whether to truncate the Performance Schema `events_statements_history_long` and `events_stages_history_long` tables before starting.
- `in_auto_enable BOOLEAN`: Whether to automatically enable required consumers.

## Example

```
mysql> CALL sys.ps_trace_statement_digest('891ec6860f98ba46d89dd20b0c03652c', 10, 0.1, TRUE, TRUE);
+-----+

```

### 26.4.4.23 The ps\_trace\_thread() Procedure

Dumps all Performance Schema data for an instrumented thread to a `.dot` formatted graph file (for the DOT graph description language). Each result set returned from the procedure should be used for a complete graph.

This procedure disables binary logging during its execution by manipulating the session value of the `sql_log_bin` system variable. That is a restricted operation, so the procedure requires privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

#### Parameters

- `in_thread_id INT`: The thread to trace.
- `in_outfile VARCHAR(255)`: The name to use for the `.dot` output file.
- `in_max_runtime DECIMAL(20,2)`: The maximum number of seconds (which can be fractional) to collect data. Use `NULL` to collect data for the default of 60 seconds.
- `in_interval DECIMAL(20,2)`: The number of seconds (which can be fractional) to sleep between data collections. Use `NULL` to sleep for the default of 1 second.
- `in_start_fresh BOOLEAN`: Whether to reset all Performance Schema data before tracing.
- `in_auto_setup BOOLEAN`: Whether to disable all other threads and enable all instruments and consumers. This also resets the settings at the end of the run.
- `in_debug BOOLEAN`: Whether to include `file:lineno` information in the graph.

#### Example

```
mysql> CALL sys.ps_trace_thread(25, CONCAT('/tmp/stack-', REPLACE(NOW(), ' ', '-'), '.dot'), NULL, NULL, TRUE);
+-----+
| summary |
+-----+
| Disabled 1 thread |

| Convert to PDF |
+-----+
```

```
+-----+
| dot -Tpdf -o /tmp/stack_25.pdf /tmp/stack-2014-02-16-21:18:41.dot |
+-----+
1 row in set (60.07 sec)

+-----+
| Convert to PNG
+-----+
| dot -Tpng -o /tmp/stack_25.png /tmp/stack-2014-02-16-21:18:41.dot |
+-----+
1 row in set (60.07 sec)

+-----+
| summary |
+-----+
| Enabled 1 thread |
+-----+
1 row in set (60.32 sec)
```

#### 26.4.4.24 The `ps_truncate_all_tables()` Procedure

Truncates all Performance Schema summary tables, resetting all aggregated instrumentation as a snapshot. Produces a result set indicating how many tables were truncated.

##### Parameters

- `in_verbose BOOLEAN`: Whether to display each `TRUNCATE TABLE` statement before executing it.

##### Example

```
mysql> CALL sys.ps_truncate_all_tables(FALSE);
+-----+
| summary |
+-----+
| Truncated 44 tables |
+-----+
```

#### 26.4.4.25 The `statement_performance_analyzer()` Procedure

Creates a report of the statements running on the server. The views are calculated based on the overall and/or delta activity.

This procedure disables binary logging during its execution by manipulating the session value of the `sql_log_bin` system variable. That is a restricted operation, so the procedure requires privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

##### Parameters

- `in_action ENUM('snapshot', 'overall', 'delta', 'create_tmp', 'create_table', 'save', 'cleanup')`: The action to take. These values are permitted:
  - `snapshot`: Store a snapshot. The default is to make a snapshot of the current content of the Performance Schema `events_statements_summary_by_digest` table. By setting `in_table`, this can be overwritten to copy the content of the specified table. The snapshot is stored in the `sys` schema `tmp_digests` temporary table.
  - `overall`: Generate an analysis based on the content of the table specified by `in_table`. For the overall analysis, `in_table` can be `NOW()` to use a fresh snapshot. This overwrites an existing snapshot. Use `NULL` for `in_table` to use the existing snapshot. If `in_table` is `NULL` and no snapshot exists, a new snapshot is created. The `in_views` parameter and the `statement_performance_analyzer.limit` configuration option affect the operation of this procedure.
  - `delta`: Generate a delta analysis. The delta is calculated between the reference table specified by `in_table` and the snapshot, which must exist. This action uses the `sys`

schema `tmp_digests_delta` temporary table. The `in_views` parameter and the `statement_performance_analyzer.limit` configuration option affect the operation of this procedure.

- `create_table`: Create a regular table suitable for storing the snapshot for later use (for example, for calculating deltas).
- `create_tmp`: Create a temporary table suitable for storing the snapshot for later use (for example, for calculating deltas).
- `save`: Save the snapshot in the table specified by `in_table`. The table must exist and have the correct structure. If no snapshot exists, a new snapshot is created.
- `cleanup`: Remove the temporary tables used for the snapshot and delta.
- `in_table VARCHAR(129)`: The table parameter used for some of the actions specified by the `in_action` parameter. Use the format `db_name.tbl_name` or `tbl_name` without using any backtick (`) identifier-quoting characters. Periods (.) are not supported in database and table names.

The meaning of the `in_table` value for each `in_action` value is detailed in the individual `in_action` value descriptions.

- `in_views SET ('with_runtimes_in_95th_percentile', 'analysis', 'with_errors_or_warnings', 'with_full_table_scans', 'with_sorting', 'with_temp_tables', 'custom')`: Which views to include. This parameter is a `SET` value, so it can contain multiple view names, separated by commas. The default is to include all views except `custom`. The following values are permitted:
  - `with_runtimes_in_95th_percentile`: Use the `statements_with_runtimes_in_95th_percentile` view.
  - `analysis`: Use the `statement_analysis` view.
  - `with_errors_or_warnings`: Use the `statements_with_errors_or_warnings` view.
  - `with_full_table_scans`: Use the `statements_with_full_table_scans` view.
  - `with_sorting`: Use the `statements_with_sorting` view.
  - `with_temp_tables`: Use the `statements_with_temp_tables` view.
  - `custom`: Use a custom view. This view must be specified using the `statement_performance_analyzer.view` configuration option to name a query or an existing view.

## Configuration Options

`statement_performance_analyzer()` operation can be modified using the following configuration options or their corresponding user-defined variables (see [Section 26.4.2.1, “The sys\\_config Table”](#)):

- `debug, @sys.debug`

If this option is `ON`, produce debugging output. The default is `OFF`.

- `statement_performance_analyzer.limit, @sys.statement_performance_analyzer.limit`

The maximum number of rows to return for views that have no built-in limit. The default is 100.

- `statement_performance_analyzer.view, @sys.statement_performance_analyzer.view`

The custom query or view to be used. If the option value contains a space, it is interpreted as a query. Otherwise, it must be the name of an existing view that queries the Performance Schema `events_statements_summary_by_digest` table. There cannot be any `LIMIT` clause in the query or view definition if the `statement_performance_analyzer.limit` configuration option is greater than 0. If specifying a view, use the same format as for the `in_table` parameter. The default is `NULL` (no custom view defined).

## Example

To create a report with the queries in the 95th percentile since the last truncation of `events_statements_summary_by_digest` and with a one-minute delta period:

1. Create a temporary table to store the initial snapshot.
2. Create the initial snapshot.
3. Save the initial snapshot in the temporary table.
4. Wait one minute.
5. Create a new snapshot.
6. Perform analysis based on the new snapshot.
7. Perform analysis based on the delta between the initial and new snapshots.

```
mysql> CALL sys.statement_performance_analyzer('create_tmp', 'mydb.tmp_digests_ini', NULL);
Query OK, 0 rows affected (0.08 sec)

mysql> CALL sys.statement_performance_analyzer('snapshot', NULL, NULL);
Query OK, 0 rows affected (0.02 sec)

mysql> CALL sys.statement_performance_analyzer('save', 'mydb.tmp_digests_ini', NULL);
Query OK, 0 rows affected (0.00 sec)

mysql> DO SLEEP(60);
Query OK, 0 rows affected (1 min 0.00 sec)

mysql> CALL sys.statement_performance_analyzer('snapshot', NULL, NULL);
Query OK, 0 rows affected (0.02 sec)

mysql> CALL sys.statement_performance_analyzer('overall', NULL, 'with_runtimes_in_95th_percentile');
+-----+
| Next Output |
+-----+
| Queries with Runtime in 95th Percentile |
+-----+
1 row in set (0.05 sec)

...
mysql> CALL sys.statement_performance_analyzer('delta', 'mydb.tmp_digests_ini', 'with_runtimes_in_95th_percentile');
+-----+
| Next Output |
+-----+
| Queries with Runtime in 95th Percentile |
+-----+
1 row in set (0.03 sec)

...
```

Create an overall report of the 95th percentile queries and the top 10 queries with full table scans:

```
mysql> CALL sys.statement_performance_analyzer('snapshot', NULL, NULL);
Query OK, 0 rows affected (0.01 sec)

mysql> SET @sys.statement_performance_analyzer.limit = 10;
```

```
Query OK, 0 rows affected (0.00 sec)

mysql> CALL sys.statement_performance_analyzer('overall', NULL, 'with_runtimes_in_95th_percentile,with_full
+-----+
| Next Output
+-----+
| Queries with Runtime in 95th Percentile |
+-----+
1 row in set (0.01 sec)

...
+-----+
| Next Output
+-----+
| Top 10 Queries with Full Table Scan |
+-----+
1 row in set (0.09 sec)

...
```

Use a custom view showing the top 10 queries sorted by total execution time, refreshing the view every minute using the `watch` command in Linux:

```
mysql> CREATE OR REPLACE VIEW mydb.my_statements AS
 SELECT sys.format_statement(DIGEST_TEXT) AS query,
 SCHEMA_NAME AS db,
 COUNT_STAR AS exec_count,
 sys.format_time(SUM_TIMER_WAIT) AS total_latency,
 sys.format_time(AVG_TIMER_WAIT) AS avg_latency,
 ROUND(IFNULL(SUM_ROWS_SENT / NULLIF(COUNT_STAR, 0), 0)) AS rows_sent_avg,
 ROUND(IFNULL(SUM_ROWS_EXAMINED / NULLIF(COUNT_STAR, 0), 0)) AS rows_examined_avg,
 ROUND(IFNULL(SUM_ROWS_AFFECTED / NULLIF(COUNT_STAR, 0), 0)) AS rows_affected_avg,
 DIGEST AS digest
 FROM performance_schema.events_statements_summary_by_digest
 ORDER BY SUM_TIMER_WAIT DESC;
Query OK, 0 rows affected (0.10 sec)

mysql> CALL sys.statement_performance_analyzer('create_table', 'mydb.digests_prev', NULL);
Query OK, 0 rows affected (0.10 sec)

shell> watch -n 60 "mysql sys --table -e \
> SET @sys.statement_performance_analyzer.view = 'mydb.my_statements';
> SET @sys.statement_performance_analyzer.limit = 10;
> CALL statement_performance_analyzer('snapshot', NULL, NULL);
> CALL statement_performance_analyzer('delta', 'mydb.digests_prev', 'custom');
> CALL statement_performance_analyzer('save', 'mydb.digests_prev', NULL);
> \""
Every 60.0s: mysql sys --table -e " ... Mon Dec 22 10:58:51 2014

+-----+
| Next Output

```

#### 26.4.4.26 The `table_exists()` Procedure

Tests whether a given table exists as a regular table, a `TEMPORARY` table, or a view. The procedure returns the table type in an `OUT` parameter. If both a temporary and a permanent table exist with the given name, `TEMPORARY` is returned.

##### Parameters

- `in_db VARCHAR(64)`: The name of the database in which to check for table existence.

- `in_table VARCHAR(64)`: The name of the table to check the existance of.
- `out_exists ENUM(' ', 'BASE TABLE', 'VIEW', 'TEMPORARY')`: The return value. This is an `OUT` parameter, so it must be a variable into which the table type can be stored. When the procedure returns, the variable has one of the following values to indicate whether the table exists:
  - `' '`: The table name does not exist as a base table, `TEMPORARY` table, or view.
  - `BASE TABLE`: The table name exists as a base (permanent) table.
  - `VIEW`: The table name exists as a view.
  - `TEMPORARY`: The table name exists as a `TEMPORARY` table.

## Example

```

mysql> CREATE DATABASE db1;
Query OK, 1 row affected (0.01 sec)

mysql> USE db1;
Database changed
mysql> CREATE TABLE t1 (id INT PRIMARY KEY);
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TABLE t2 (id INT PRIMARY KEY);
Query OK, 0 rows affected (0.20 sec)

mysql> CREATE view v_t1 AS SELECT * FROM t1;
Query OK, 0 rows affected (0.02 sec)

mysql> CREATE TEMPORARY TABLE t1 (id INT PRIMARY KEY);
Query OK, 0 rows affected (0.00 sec)

mysql> CALL sys.table_exists('db1', 't1', @exists); SELECT @exists;
Query OK, 0 rows affected (0.01 sec)

+-----+
| @exists |
+-----+
| TEMPORARY |
+-----+
1 row in set (0.00 sec)

mysql> CALL sys.table_exists('db1', 't2', @exists); SELECT @exists;
Query OK, 0 rows affected (0.02 sec)

+-----+
| @exists |
+-----+
| BASE TABLE |
+-----+
1 row in set (0.00 sec)

mysql> CALL sys.table_exists('db1', 'v_t1', @exists); SELECT @exists;
Query OK, 0 rows affected (0.02 sec)

+-----+
| @exists |
+-----+
| VIEW |
+-----+
1 row in set (0.00 sec)

mysql> CALL sys.table_exists('db1', 't3', @exists); SELECT @exists;
Query OK, 0 rows affected (0.00 sec)

+-----+
| @exists |
+-----+
| |
+-----+

```

```
+-----+
1 row in set (0.00 sec)
```

## 26.4.5 sys Schema Stored Functions

The following sections describe `sys` schema stored functions.

### 26.4.5.1 The `extract_schema_from_file_name()` Function

Given a file path name, returns the path component that represents the schema name. This function assumes that the file name lies within the schema directory. For this reason, it does not work with partitions or tables defined using their own `DATA_DIRECTORY` table option.

This function is useful when extracting file I/O information from the Performance Schema that includes file path names. It provides a convenient way to display schema names, which can be more easily understood than full path names, and can be used in joins against object schema names.

#### Parameters

- `path` `VARCHAR(512)`: The full path to a data file from which to extract the schema name.

#### Return Value

A `VARCHAR(64)` value.

#### Example

```
mysql> SELECT sys.extract_schema_from_file_name('/usr/local/mysql/data/world/City.ibd');
+-----+
| sys.extract_schema_from_file_name('/usr/local/mysql/data/world/City.ibd') |
+-----+
| world |
+-----+
```

### 26.4.5.2 The `extract_table_from_file_name()` Function

Given a file path name, returns the path component that represents the table name.

This function is useful when extracting file I/O information from the Performance Schema that includes file path names. It provides a convenient way to display table names, which can be more easily understood than full path names, and can be used in joins against object table names.

#### Parameters

- `path` `VARCHAR(512)`: The full path to a data file from which to extract the table name.

#### Return Value

A `VARCHAR(64)` value.

#### Example

```
mysql> SELECT sys.extract_table_from_file_name('/usr/local/mysql/data/world/City.ibd');
+-----+
| sys.extract_table_from_file_name('/usr/local/mysql/data/world/City.ibd') |
+-----+
| City |
+-----+
```

### 26.4.5.3 The `format_bytes()` Function

Given a byte count, converts it to human-readable format and returns a string consisting of a value and a units indicator. Depending on the size of the value, the units part is `bytes`, `KiB` (kilobytes), `MiB` (mebibytes), `GiB` (gibibytes), `TiB` (tebibytes), or `PiB` (pebibytes).

## Parameters

- `bytes TEXT`: The byte count to format.

## Return Value

A `TEXT` value.

## Example

```
mysql> SELECT sys.format_bytes(512), sys.format_bytes(18446644073709551615);
+-----+-----+
| sys.format_bytes(512) | sys.format_bytes(18446644073709551615) |
+-----+-----+
| 512 bytes | 16383.91 PiB |
+-----+-----+
```

### 26.4.5.4 The `format_path()` Function

Given a path name, returns the modified path name after replacing subpaths that match the values of the following system variables, in order:

```
datadir
tmpdir
slave_load_tmpdir
innodb_data_home_dir
innodb_log_group_home_dir
innodb_undo_directory
basedir
```

A value that matches the value of system variable `sysvar` is replaced with the string `@@GLOBAL.sysvar`.

Prior to MySQL 5.7.14, backslashes in Windows path names are converted to forward slashes in the result.

## Parameters

- `path VARCHAR(512)`: The path name to format.

## Return Value

A `VARCHAR(512)` `CHARACTER SET utf8` value.

## Example

```
mysql> SELECT sys.format_path('/usr/local/mysql/data/world/City.ibd');
+-----+
| sys.format_path('/usr/local/mysql/data/world/City.ibd') |
+-----+
| /usr/local/mysql/data/world/City.ibd |
+-----+
```

### 26.4.5.5 The `format_statement()` Function

Given a string (normally representing an SQL statement), reduces it to the length given by the `statement_truncate_len` configuration option, and returns the result. No truncation occurs if the string is shorter than `statement_truncate_len`. Otherwise, the middle part of the string is replaced by an ellipsis (...).

This function is useful for formatting possibly lengthy statements retrieved from Performance Schema tables to a known fixed maximum length.

## Parameters

- `statement LONGTEXT`: The statement to format.

## Configuration Options

`format_statement()` operation can be modified using the following configuration options or their corresponding user-defined variables (see [Section 26.4.2.1, “The sys\\_config Table”](#)):

- `statement_truncate_len`, `@sys.statement_truncate_len`

The maximum length of statements returned by the `format_statement()` function. Longer statements are truncated to this length. The default is 64.

## Return Value

A `LONGTEXT` value.

## Example

By default, `format_statement()` truncates statements to be no more than 64 characters. Setting `@sys.statement_truncate_len` changes the truncation length for the current session:

```
mysql> SET @stmt = 'SELECT variable, value, set_time, set_by FROM sys_config';
mysql> SELECT sys.format_statement(@stmt);
+-----+
| sys.format_statement(@stmt) |
+-----+
| SELECT variable, value, set_time, set_by FROM sys_config |
+-----+
mysql> SET @sys.statement_truncate_len = 32;
mysql> SELECT sys.format_statement(@stmt);
+-----+
| sys.format_statement(@stmt) |
+-----+
| SELECT variabl ... ROM sys_config |
+-----+
```

## 26.4.5.6 The `format_time()` Function

Given a Performance Schema latency or wait time in picoseconds, converts it to human-readable format and returns a string consisting of a value and a units indicator. Depending on the size of the value, the units part is `ps` (picoseconds), `ns` (nanoseconds), `us` (microseconds), `ms` (milliseconds), `s` (seconds), `m` (minutes), `h` (hours), `d` (days), or `w` (weeks).

## Parameters

- `picoseconds TEXT`: The picoseconds value to format.

## Return Value

A `TEXT` value.

## Example

```
mysql> SELECT sys.format_time(3501), sys.format_time(188732396662000);
+-----+-----+
| sys.format_time(3501) | sys.format_time(188732396662000) |
+-----+-----+
| 3.50 ns | 3.15 m |
+-----+-----+
```

## 26.4.5.7 The `list_add()` Function

Adds a value to a comma-separated list of values and returns the result.

This function and `list_drop()` can be useful for manipulating the value of system variables such as `sql_mode` and `optimizer_switch` that take a comma-separated list of values.

## Parameters

- `in_list TEXT`: The list to be modified.
- `in_add_value TEXT`: The value to add to the list.

## Return Value

A `TEXT` value.

## Example

```
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES |
+-----+
mysql> SET @@sql_mode = sys.list_add(@@sql_mode, 'NO_ENGINE_SUBSTITUTION');
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION |
+-----+
mysql> SET @@sql_mode = sys.list_drop(@@sql_mode, 'ONLY_FULL_GROUP_BY');
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION |
+-----+
```

### 26.4.5.8 The `list_drop()` Function

Removes a value from a comma-separated list of values and returns the result. For more information, see the description of [list\\_add\(\)](#)

## Parameters

- `in_list TEXT`: The list to be modified.
- `in_drop_value TEXT`: The value to drop from the list.

## Return Value

A `TEXT` value.

### 26.4.5.9 The `ps_is_account_enabled()` Function

Returns `YES` or `NO` to indicate whether Performance Schema instrumentation for a given account is enabled.

## Parameters

- `in_host VARCHAR(60)`: The host name of the account to check.
- `in_user VARCHAR(32)`: The user name of the account to check.

## Return Value

An `ENUM('YES', 'NO')` value.

## Example

```
mysql> SELECT sys.ps_is_account_enabled('localhost', 'root');
```

```
+-----+
| sys.ps_is_account_enabled('localhost', 'root') |
+-----+
| YES |
+-----+
```

### 26.4.5.10 The ps\_is\_consumer\_enabled() Function

Returns `YES` or `NO` to indicate whether a given Performance Schema consumer is enabled, or `NULL` if the argument is `NULL`. If the argument is not a valid consumer name, an error occurs. (Prior to MySQL 5.7.28, the function returns `NULL` if the argument is not a valid consumer name.)

This function accounts for the consumer hierarchy, so a consumer is not considered enabled unless all consumers on which depends are also enabled. For information about the consumer hierarchy, see [Section 25.4.7, “Pre-Filtering by Consumer”](#).

#### Parameters

- `in_consumer VARCHAR(64)`: The name of the consumer to check.

#### Return Value

An `ENUM( 'YES' , 'NO' )` value.

#### Example

```
mysql> SELECT sys.ps_is_consumer_enabled('thread_instrumentation');
+-----+
| sys.ps_is_consumer_enabled('thread_instrumentation') |
+-----+
| YES |
+-----+
```

### 26.4.5.11 The ps\_is\_instrument\_default\_enabled() Function

Returns `YES` or `NO` to indicate whether a given Performance Schema instrument is enabled by default.

#### Parameters

- `in_instrument VARCHAR(128)`: The name of the instrument to check.

#### Return Value

An `ENUM( 'YES' , 'NO' )` value.

#### Example

```
mysql> SELECT sys.ps_is_instrument_default_enabled('memory/innodb/row_log_buf');
+-----+
| sys.ps_is_instrument_default_enabled('memory/innodb/row_log_buf') |
+-----+
| NO |
+-----+
mysql> SELECT sys.ps_is_instrument_default_enabled('statement/sql/alter_user');
+-----+
| sys.ps_is_instrument_default_enabled('statement/sql/alter_user') |
+-----+
| YES |
+-----+
```

### 26.4.5.12 The ps\_is\_instrument\_default\_timed() Function

Returns `YES` or `NO` to indicate whether a given Performance Schema instrument is timed by default.

## Parameters

- `in_instrument VARCHAR(128)`: The name of the instrument to check.

## Return Value

An `ENUM('YES', 'NO')` value.

## Example

```
mysql> SELECT sys.ps_is_instrument_default_timed('memory/innodb/row_log_buf');
+-----+
| sys.ps_is_instrument_default_timed('memory/innodb/row_log_buf') |
+-----+
| NO
+-----+
mysql> SELECT sys.ps_is_instrument_default_timed('statement/sql/alter_user');
+-----+
| sys.ps_is_instrument_default_timed('statement/sql/alter_user') |
+-----+
| YES
+-----+
```

## 26.4.5.13 The `ps_is_thread_instrumented()` Function

Returns `YES` or `NO` to indicate whether Performance Schema instrumentation for a given connection ID is enabled, `UNKNOWN` if the ID is unknown, or `NULL` if the ID is `NULL`.

## Parameters

- `in_connection_id BIGINT UNSIGNED`: The connection ID. This is a value of the type given in the `PROCESSLIST_ID` column of the Performance Schema `threads` table or the `Id` column of `SHOW PROCESSLIST` output.

## Return Value

An `ENUM('YES', 'NO', 'UNKNOWN')` value.

## Example

```
mysql> SELECT sys.ps_is_thread_instrumented(43);
+-----+
| sys.ps_is_thread_instrumented(43) |
+-----+
| UNKNOWN
+-----+
mysql> SELECT sys.ps_is_thread_instrumented(CONNECTION_ID());
+-----+
| sys.ps_is_thread_instrumented(CONNECTION_ID()) |
+-----+
| YES
+-----+
```

## 26.4.5.14 The `ps_thread_account()` Function

Given a Performance Schema thread ID, returns the `user_name@host_name` account associated with the thread.

## Parameters

- `in_thread_id BIGINT UNSIGNED`: The thread ID for which to return the account. The value should match the `THREAD_ID` column from some Performance Schema `threads` table row.

## Return Value

A `TEXT` value.

## Example

```
mysql> SELECT sys.ps_thread_account(sys.ps_thread_id(CONNECTION_ID()));
+-----+
| sys.ps_thread_account(sys.ps_thread_id(CONNECTION_ID())) |
+-----+
| root@localhost |
+-----+
```

### 26.4.5.15 The ps\_thread\_id() Function

Returns the Performance Schema thread ID assigned to a given connection ID, or the thread ID for the current connection if the connection ID is `NULL`.

#### Parameters

- `in_connection_id BIGINT UNSIGNED`: The ID of the connection for which to return the thread ID. This is a value of the type given in the `PROCESSLIST_ID` column of the Performance Schema `threads` table or the `Id` column of `SHOW PROCESSLIST` output.

#### Return Value

A `BIGINT UNSIGNED` value.

## Example

```
mysql> SELECT sys.ps_thread_id(260);
+-----+
| sys.ps_thread_id(260) |
+-----+
| 285 |
+-----+
```

### 26.4.5.16 The ps\_thread\_stack() Function

Returns a JSON formatted stack of all statements, stages, and events within the Performance Schema for a given thread ID.

#### Parameters

- `in_thread_id BIGINT`: The ID of the thread to trace. The value should match the `THREAD_ID` column from some Performance Schema `threads` table row.
- `in_verbose BOOLEAN`: Whether to include `file:lineno` information in the events.

#### Return Value

A `LONGTEXT CHARACTER SET latin1` value.

## Example

```
mysql> SELECT sys.ps_thread_stack(37, FALSE) AS thread_stack\G
***** 1. row *****
thread_stack: {"rankdir": "LR", "nodesep": "0.10",
"stack_created": "2014-02-19 13:39:03", "mysql_version": "5.7.3-m13",
"mysql_user": "root@localhost", "events": [{"nesting_event_id": "0",
"event_id": "10", "timer_wait": 256.35, "event_info": "sql/select",
"wait_info": "select @@version_comment limit 1\nerrors: 0\nwarnings: 0\nlock time:
..."}]
```

### 26.4.5.17 The ps\_thread\_trx\_info() Function

Returns a JSON object containing information about a given thread. The information includes the current transaction, and the statements it has already executed, derived from the Performance Schema

`events_transactions_current` and `events_statements_history` tables. (The consumers for those tables must be enabled to obtain full data in the JSON object.)

If the output exceeds the truncation length (65535 by default), a JSON error object is returned, such as:

```
{ "error": "Trx info truncated: Row 6 was cut by GROUP_CONCAT()" }
```

Similar error objects are returned for other warnings and exceptions raised during function execution.

## Parameters

- `in_thread_id BIGINT UNSIGNED`: The thread ID for which to return transaction information. The value should match the `THREAD_ID` column from some Performance Schema `threads` table row.

## Configuration Options

`ps_thread_trx_info()` operation can be modified using the following configuration options or their corresponding user-defined variables (see [Section 26.4.2.1, “The sys\\_config Table”](#)):

- `ps_thread_trx_info.max_length`, `@sys.ps_thread_trx_info.max_length`

The maximum length of the output. The default is 65535.

## Return Value

A `LONGTEXT` value.

## Example

```
mysql> SELECT sys.ps_thread_trx_info(48)\G
***** 1. row *****
sys.ps_thread_trx_info(48): [
 {
 "time": "790.70 us",
 "state": "COMMITTED",
 "mode": "READ WRITE",
 "autocommitted": "NO",
 "gtid": "AUTOMATIC",
 "isolation": "REPEATABLE READ",
 "statements_executed": [
 {
 "sql_text": "INSERT INTO info VALUES (1, \\'foo\\')",
 "time": "471.02 us",
 "schema": "trx",
 "rows_examined": 0,
 "rows_affected": 1,
 "rows_sent": 0,
 "tmp_tables": 0,
 "tmp_disk_tables": 0,
 "sort_rows": 0,
 "sort_merge_passes": 0
 },
 {
 "sql_text": "COMMIT",
 "time": "254.42 us",
 "schema": "trx",
 "rows_examined": 0,
 "rows_affected": 0,
 "rows_sent": 0,
 "tmp_tables": 0,
 "tmp_disk_tables": 0,
 "sort_rows": 0,
 "sort_merge_passes": 0
 }
],
 "time": "426.20 us",
 "state": "COMMITTED",
 }
]
```

```
"mode": "READ WRITE",
"autocommitted": "NO",
"gtid": "AUTOMATIC",
"isolation": "REPEATABLE READ",
"statements_executed": [
 {
 "sql_text": "INSERT INTO info VALUES (2, \\'bar\\')",
 "time": "107.33 us",
 "schema": "trx",
 "rows_examined": 0,
 "rows_affected": 1,
 "rows_sent": 0,
 "tmp_tables": 0,
 "tmp_disk_tables": 0,
 "sort_rows": 0,
 "sort_merge_passes": 0
 },
 {
 "sql_text": "COMMIT",
 "time": "213.23 us",
 "schema": "trx",
 "rows_examined": 0,
 "rows_affected": 0,
 "rows_sent": 0,
 "tmp_tables": 0,
 "tmp_disk_tables": 0,
 "sort_rows": 0,
 "sort_merge_passes": 0
 }
]
}]
```

#### 26.4.5.18 The quote\_identifier() Function

Given a string argument, this function produces a quoted identifier suitable for inclusion in SQL statements. This is useful when a value to be used as an identifier is a reserved word or contains backtick (`) characters. It was added in MySQL 5.7.14.

##### Parameters

`in_identifier TEXT`: The identifier to quote.

##### Return Value

A `TEXT` value.

##### Example

```
mysql> SELECT sys.quote_identifier('plain');
+-----+
| sys.quote_identifier('plain') |
+-----+
| `plain` |
+-----+
mysql> SELECT sys.quote_identifier('trick`ier');
+-----+
| sys.quote_identifier('trick`ier') |
+-----+
| `trick``ier` |
+-----+
mysql> SELECT sys.quote_identifier('integer');
+-----+
| sys.quote_identifier('integer') |
+-----+
| `integer` |
+-----+
```

#### 26.4.5.19 The sys\_get\_config() Function

Given a configuration option name, returns the option value from the `sys_config` table, or the provided default value (which may be `NULL`) if the option does not exist in the table.

If `sys_get_config()` returns the default value and that value is `NULL`, it is expected that the caller is able to handle `NULL` for the given configuration option.

By convention, routines that call `sys_get_config()` first check whether the corresponding user-defined variable exists and is non-`NULL`. If so, the routine uses the variable value without reading the `sys_config` table. If the variable does not exist or is `NULL`, the routine reads the option value from the table and sets the user-defined variable to that value. For more information about the relationship between configuration options and their corresponding user-defined variables, see [Section 26.4.2.1, “The sys\\_config Table”](#).

If you want to check whether the configuration option has already been set and, if not, use the return value of `sys_get_config()`, you can use `IFNULL(...)` (see example later). However, this should not be done inside a loop (for example, for each row in a result set) because for repeated calls where the assignment is needed only in the first iteration, using `IFNULL(...)` is expected to be significantly slower than using an `IF (...) THEN ... END IF;` block (see example later).

## Parameters

- `in_variable_name VARCHAR(128)`: The name of the configuration option for which to return the value.
- `in_default_value VARCHAR(128)`: The default value to return if the configuration option is not found in the `sys_config` table.

## Return Value

A `VARCHAR(128)` value.

## Example

Get a configuration value from the `sys_config` table, falling back to 128 as the default if the option is not present in the table:

```
mysql> SELECT sys.sys_get_config('statement_truncate_len', 128) AS Value;
+-----+
| Value |
+-----+
| 64 |
+-----+
```

One-liner example: Check whether the option is already set; if not, assign the `IFNULL(...)` result (using the value from the `sys_config` table):

```
mysql> SET @sys.statement_truncate_len =
 IFNULL(@sys.statement_truncate_len,
 sys.sys_get_config('statement_truncate_len', 64));
```

`IF (...) THEN ... END IF;` block example: Check whether the option is already set; if not, assign the value from the `sys_config` table:

```
IF (@sys.statement_truncate_len IS NULL) THEN
 SET @sys.statement_truncate_len = sys.sys_get_config('statement_truncate_len', 64);
END IF;
```

## 26.4.5.20 The version\_major() Function

This function returns the major version of the MySQL server.

## Parameters

None.

## Return Value

A `TINYINT UNSIGNED` value.

## Example

```
mysql> SELECT VERSION(), sys.version_major();
+-----+-----+
| VERSION() | sys.version_major() |
+-----+-----+
| 5.7.24-debug-log | 5 |
+-----+-----+
```

### 26.4.5.21 The `version_minor()` Function

This function returns the minor version of the MySQL server.

## Parameters

None.

## Return Value

A `TINYINT UNSIGNED` value.

## Example

```
mysql> SELECT VERSION(), sys.version_minor();
+-----+-----+
| VERSION() | sys.version_minor() |
+-----+-----+
| 5.7.24-debug-log | 7 |
+-----+-----+
```

### 26.4.5.22 The `version_patch()` Function

This function returns the patch release version of the MySQL server.

## Parameters

None.

## Return Value

A `TINYINT UNSIGNED` value.

## Example

```
mysql> SELECT VERSION(), sys.version_patch();
+-----+-----+
| VERSION() | sys.version_patch() |
+-----+-----+
| 5.7.24-debug-log | 24 |
+-----+-----+
```

---

MySQL Connectors provide connectivity to the MySQL server for client programs. APIs provide low-level access to MySQL resources using either the classic MySQL protocol or X Protocol. Both Connectors and the APIs enable you to connect and execute MySQL statements from another language or environment, including ODBC, Java (JDBC), C++, Python, PHP, Perl, Ruby, and native C and embedded MySQL instances.

## MySQL Connectors

Oracle develops a number of connectors:

- [Connector/C++](#) enables C++ applications to connect to MySQL.
- [Connector/J](#) provides driver support for connecting to MySQL from Java applications using the standard Java Database Connectivity (JDBC) API.
- [Connector/.NET](#) enables developers to create .NET applications that connect to MySQL. Connector/.NET implements a fully functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that use Connector/.NET can be written in any supported .NET language.

[MySQL for Visual Studio](#) works with Connector/.NET and Microsoft Visual Studio 2012, 2013, 2015, and 2017. MySQL for Visual Studio provides access to MySQL objects and data from Visual Studio. As a Visual Studio package, it integrates directly into Server Explorer providing the ability to create new connections and work with MySQL database objects.

- [Connector/ODBC](#) provides driver support for connecting to MySQL using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix, and macOS platforms.
- [Connector/Python](#) provides driver support for connecting to MySQL from Python applications using an API that is compliant with the [Python DB API version 2.0](#). No additional Python modules or MySQL client libraries are required.

## The MySQL C API

For direct access to using MySQL natively within a C application, there are two methods:

- The [C API](#) provides low-level access to the MySQL client/server protocol through the `libmysqlclient` client library. This is the primary method used to connect to an instance of the MySQL server, and is used both by MySQL command-line clients and many of the MySQL Connectors and third-party APIs detailed here.

`libmysqlclient` is included in MySQL distributions.

- `libmysqld` is an embedded MySQL server library that enables you to embed an instance of the MySQL server into your C applications.

`libmysqld` is included in MySQL distributions.

### Note

The `libmysqld` embedded server library is deprecated as of MySQL 5.7.19 and is removed in MySQL 8.0.

See also [MySQL C API Implementations](#).

To access MySQL from a C application, or to build an interface to MySQL for a language not supported by the Connectors or APIs in this chapter, the [C API](#) is where to start. A number of programmer's utilities are available to help with the process; see [Section 4.7, “Program Development Utilities”](#).

## Third-Party MySQL APIs

The remaining APIs described in this chapter provide an interface to MySQL from specific application languages. These third-party solutions are not developed or supported by Oracle. Basic information on their usage and abilities is provided here for reference purposes only.

All the third-party language APIs are developed using one of two methods, using `libmysqlclient` or by implementing a *native driver*. The two solutions offer different benefits:

- Using `libmysqlclient` offers complete compatibility with MySQL because it uses the same libraries as the MySQL client applications. However, the feature set is limited to the implementation and interfaces exposed through `libmysqlclient` and the performance may be lower as data is copied between the native language, and the MySQL API components.
- *Native drivers* are an implementation of the MySQL network protocol entirely within the host language or environment. Native drivers are fast, as there is less copying of data between components, and they can offer advanced functionality not available through the standard MySQL API. Native drivers are also easier for end users to build and deploy because no copy of the MySQL client libraries is needed to build the native driver components.

[Table 27.1, “MySQL APIs and Interfaces”](#) lists many of the libraries and interfaces available for MySQL.

**Table 27.1 MySQL APIs and Interfaces**

| Environment | API                    | Type                        | Notes                                                        |
|-------------|------------------------|-----------------------------|--------------------------------------------------------------|
| Ada         | GNU Ada MySQL Bindings | <code>libmysqlclient</code> | <a href="#">See MySQL Bindings for GNU Ada</a>               |
| C           | C API                  | <code>libmysqlclient</code> | <a href="#">See MySQL 5.7 C API Developer Guide.</a>         |

## 27.1 MySQL Connector/C++

The MySQL Connector/C++ manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: [MySQL Connector/C++ 8.0 Developer Guide](#)
- Release notes: [MySQL Connector/C++ Release Notes](#)

## 27.2 MySQL Connector/J

The MySQL Connector/J manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: [MySQL Connector/J Developer Guide](#)
- Release notes: [MySQL Connector/J Release Notes](#)

## 27.3 MySQL Connector/.NET

The MySQL Connector/.NET manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: [MySQL Connector/.NET Developer Guide](#)
- Release notes: [MySQL Connector/.NET Release Notes](#)

## 27.4 MySQL Connector/ODBC

The MySQL Connector/ODBC manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: [MySQL Connector/ODBC Developer Guide](#)
- Release notes: [MySQL Connector/ODBC Release Notes](#)

## 27.5 MySQL Connector/Python

The MySQL Connector/Python manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: [MySQL Connector/Python Developer Guide](#)
- Release notes: [MySQL Connector/Python Release Notes](#)

## 27.6 libmysqld, the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

### Note

The `libmysqld` embedded server library is deprecated as of MySQL 5.7.19 and is removed in MySQL 8.0.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change a threaded application to use the embedded library, you normally only have to add calls to the following functions.

**Table 27.2 MySQL Embedded Server Library Functions**

| Function                          | When to Call                                                                                             |
|-----------------------------------|----------------------------------------------------------------------------------------------------------|
| <code>mysql_library_init()</code> | Call it before any other MySQL function is called, preferably early in the <code>main()</code> function. |
| <code>mysql_library_end()</code>  | Call it before your program exits.                                                                       |
| <code>mysql_thread_init()</code>  | Call it in each thread you create that accesses MySQL.                                                   |
| <code>mysql_thread_end()</code>   | Call it before calling <code>pthread_exit()</code> .                                                     |

Then, link your code with `libmysqld.a` instead of `libmysqlclient.a`. To ensure binary compatibility between your application and the server library, always compile your application against headers for the same series of MySQL that was used to compile the server library. For example, if `libmysqld` was compiled against MySQL 5.6 headers, do not compile your application against MySQL 5.7 headers, or vice versa.

Because the `mysql_library_xxx()` functions are also included in `libmysqlclient.a`, you can change between the embedded and the client/server version by just linking your application with the right library. See [mysql\\_library\\_init\(\)](#).

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default.

### 27.6.1 Compiling Programs with libmysqld

In precompiled binary MySQL distributions that include `libmysqld`, the embedded server library, MySQL builds the library using the appropriate vendor compiler if there is one.

To get a `libmysqld` library if you build MySQL from source yourself, you should configure MySQL with the `-DWITH_EMBEDDED_SERVER=1` option. See [Section 2.9.7, “MySQL Source-Configuration Options”](#).

When you link your program with `libmysqld`, you must also include the system-specific `pthread` libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing `mysql_config --libmysqld-libs`.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.

To compile a C program to include the necessary files to embed the MySQL server library into an executable version of a program, the compiler needs to know where to find various files and needs instructions on how to compile the program. The following example shows how a program could be compiled from the command line, assuming that you are using `gcc`, use the GNU C compiler:

```
gcc mysql_test.c -o mysql_test \
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Immediately following the `gcc` command is the name of the C program source file. After it, the `-o` option is given to indicate that the file name that follows is the name that the compiler is to give to the output file, the compiled program. The next line of code tells the compiler to obtain the location of the include files and libraries and other settings for the system on which it is compiled. The `mysql_config` command is contained in backticks, not single quotation marks.

On some non-`gcc` platforms, the embedded library depends on C++ runtime libraries and linking against the embedded library might result in missing-symbol errors. To solve this, link using a C++ compiler or explicitly list the required libraries on the link command line.

### 27.6.2 Restrictions When Using the Embedded MySQL Server

The embedded server has the following limitations:

- No user-defined functions (UDFs).

- No stack trace on core dump.
- You cannot set this up as a source or a replica (no replication).
- Very large result sets may be unusable on low memory systems.
- You cannot connect to an embedded server from an outside process with sockets or TCP/IP. However, you can connect to an intermediate application, which in turn can connect to an embedded server on the behalf of a remote client or outside process.
- `libmysqld` does not support encrypted connections. An implication is that if an application linked against `libmysqld` establishes a connection to a remote server, the connection cannot be encrypted.
- `InnoDB` is not reentrant in the embedded server and cannot be used for multiple connections, either successively or simultaneously.
- The Event Scheduler is not available. Because of this, the `event_scheduler` system variable is disabled.
- The Performance Schema is not available.
- The embedded server cannot share the same `secure_file_priv` directory with another server. As of MySQL 5.7.8, the default value for this directory can be set at build time with the `INSTALL_SECURE_FILE_PRIV_EMBEDDEDDIR` CMake option.

Some of these limitations can be changed by editing the `mysql_embed.h` include file and recompiling MySQL.

### 27.6.3 Options with the Embedded Server

Any options that may be given with the `mysqld` server daemon, may be used with an embedded server library. Server options may be given in an array as an argument to the `mysql_library_init()`, which initializes the server. They also may be given in an option file like `my.cnf`. To specify an option file for a C program, use the `--defaults-file` option as one of the elements of the second argument of the `mysql_library_init()` function. See [mysql\\_library\\_init\(\)](#), for more information on the `mysql_library_init()` function.

Using option files can make it easier to switch between a client/server application and one where MySQL is embedded. Put common options under the `[server]` group. These are read by both MySQL versions. Client/server-specific options should go under the `[mysqld]` section. Put options specific to the embedded MySQL server library in the `[embedded]` section. Options specific to applications go under section labeled `[ApplicationName_SERVER]`. See [Section 4.2.2.2, “Using Option Files”](#).

### 27.6.4 Embedded Server Examples

These two example programs should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed, mostly with file paths. These examples are designed to give enough details for you to understand the problem, without the clutter that is a necessary part of a real application. The first example is very straightforward. The second example is a little more advanced with some error checking. The first is followed by a command-line entry for compiling the program. The second is followed by a GNUmake file that may be used for compiling instead.

#### Example 1

```
test1_libmysqld.c

#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>
#include "mysql.h"
```

```

MYSQL *mysql;
MYSQL_RES *results;
MYSQL_ROW record;

static char *server_options[] = \
 { "mysql_test", "--defaults-file=my.cnf", NULL };
int num_elements = (sizeof(server_options) / sizeof(char *)) - 1;

static char *server_groups[] = { "libmysqld_server",
 "libmysqld_client", NULL };

int main(void)
{
 mysql_library_init(num_elements, server_options, server_groups);
 mysql = mysql_init(NULL);
 mysql_options(mysql, MYSQL_READ_DEFAULT_GROUP, "libmysqld_client");
 mysql_options(mysql, MYSQL_OPT_USE_EMBEDDED_CONNECTION, NULL);

 mysql_real_connect(mysql, NULL, NULL, NULL, "database1", 0, NULL, 0);

 mysql_query(mysql, "SELECT column1, column2 FROM table1");

 results = mysql_store_result(mysql);

 while((record = mysql_fetch_row(results))) {
 printf("%s - %s \n", record[0], record[1]);
 }

 mysql_free_result(results);
 mysql_close(mysql);
 mysql_library_end();

 return 0;
}

```

Here is the command line for compiling the above program:

```
gcc test1_libmysqld.c -o test1_libmysqld \
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

## Example 2

To try the example, create an `test2_libmysqld` directory at the same level as the MySQL source directory. Save the `test2_libmysqld.c` source and the `GNUmakefile` in the directory, and run GNU `make` from inside the `test2_libmysqld` directory.

`test2_libmysqld.c`

```

/*
 * A simple example client, using the embedded MySQL server library
 */

#include <mysql.h>
#include <stdarg.h>
#include <stdio.h>
#include <stdlib.h>

MYSQL *db_connect(const char *dbname);
void db_disconnect(MYSQL *db);
void db_do_query(MYSQL *db, const char *query);

const char *server_groups[] = {
 "test2_libmysqld_SERVER", "embedded", "server", NULL
};

int
main(int argc, char **argv)
{
 MYSQL *one, *two;

 /* mysql_library_init() must be called before any other mysql
 * functions.

```

```
*
* You can use mysql_library_init(0, NULL, NULL), and it
* initializes the server using groups = {
* "server", "embedded", NULL
* }.
*
* In your $HOME/.my.cnf file, you probably want to put:

[test2_libmysqld_SERVER]
language = /path/to/source/of/mysql/sql/share/english

* You could, of course, modify argc and argv before passing
* them to this function. Or you could create new ones in any
* way you like. But all of the arguments in argv (except for
* argv[0], which is the program name) should be valid options
* for the MySQL server.
*
* If you link this client against the normal mysqlclient
* library, this function is just a stub that does nothing.
*/
mysql_library_init(argc, argv, (char **)server_groups);

one = db_connect("test");
two = db_connect(NULL);

db_do_query(one, "SHOW TABLE STATUS");
db_do_query(two, "SHOW DATABASES");

mysql_close(two);
mysql_close(one);

/* This must be called after all other mysql functions */
mysql_library_end();

exit(EXIT_SUCCESS);
}

static void
die(MYSQL *db, char *fmt, ...)
{
 va_list ap;
 va_start(ap, fmt);
 vfprintf(stderr, fmt, ap);
 va_end(ap);
 (void)putc('\n', stderr);
 if (db)
 db_disconnect(db);
 exit(EXIT_FAILURE);
}

MYSQL *
db_connect(const char *dbname)
{
 MYSQL *db = mysql_init(NULL);
 if (!db)
 die(db, "mysql_init failed: no memory");
 /*
 * Notice that the client and server use separate group names.
 * This is critical, because the server does not accept the
 * client's options, and vice versa.
 */
 mysql_options(db, MYSQL_READ_DEFAULT_GROUP, "test2_libmysqld_CLIENT");
 if (!mysql_real_connect(db, NULL, NULL, NULL, dbname, 0, NULL, 0))
 die(db, "mysql_real_connect failed: %s", mysql_error(db));

 return db;
}

void
db_disconnect(MYSQL *db)
{
 mysql_close(db);
```

```

}

void
db_do_query(MYSQL *db, const char *query)
{
 if (mysql_query(db, query) != 0)
 goto err;

 if (mysql_field_count(db) > 0)
 {
 MYSQL_RES *res;
 MYSQL_ROW row, end_row;
 int num_fields;

 if (!(res = mysql_store_result(db)))
 goto err;
 num_fields = mysql_num_fields(res);
 while ((row = mysql_fetch_row(res)))
 {
 (void)fputs(">> ", stdout);
 for (end_row = row + num_fields; row < end_row; ++row)
 (void)printf("%s\t", row ? (char*)*row : "NULL");
 (void)fputc('\n', stdout);
 }
 (void)fputc('\n', stdout);
 mysql_free_result(res);
 }
 else
 (void)printf("Affected rows: %lld\n", mysql_affected_rows(db));
 return;
err:
 die(db, "db_do_query failed: %s [%s]", mysql_error(db), query);
}

```

**GNUmakefile**

```

This assumes the MySQL software is installed in /usr/local/mysql
inc := /usr/local/mysql/include/mysql
lib := /usr/local/mysql/lib

If you have not installed the MySQL software yet, try this instead
#inc := $(HOME)/mysql-5.7/include
#lib := $(HOME)/mysql-5.7/libmysql

CC := gcc
CPPFLAGS := -I$(inc) -D_THREAD_SAFE -D_REENTRANT
CFLAGS := -g -W -Wall
LDFLAGS := -static
You can change -lmysqld to -lmysqlclient to use the
client/server library
LDLIBS = -L$(lib) -lmysqld -lm -lssl -lcrypt

ifeq (,$(shell grep FreeBSD /COPYRIGHT 2>/dev/null))
FreeBSD
LDFLAGS += -pthread
else
Assume Linux
LDLIBS += -lpthread
endif

This works for simple one-file test programs
sources := $(wildcard *.c)
objects := $(patsubst %.c,%o,$(sources))
targets := $(basename $(sources))

all: $(targets)

clean:
 rm -f $(targets) $(objects) *.core

```

## 27.7 MySQL C API

The MySQL C API Developer Guide is published in standalone form, not as part of the MySQL Reference Manual. See [MySQL 5.7 C API Developer Guide](#).

## 27.8 MySQL PHP API

The MySQL PHP API manual is now published in standalone form, not as part of the MySQL Reference Manual. See [MySQL and PHP](#).

## 27.9 MySQL Perl API

The Perl `DBI` module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI with MySQL, install the following:

1. The `DBI` module.
2. The `DBD::mysql` module. This is the DataBase Driver (DBD) module for Perl.
3. Optionally, the DBD module for any other type of database server you want to access.

Perl DBI is the recommended Perl interface. It replaces an older interface called `mysqlperl`, which should be considered obsolete.

These sections contain information about using Perl with MySQL and writing MySQL applications in Perl:

- For installation instructions for Perl DBI support, see [Section 2.13, “Perl Installation Notes”](#).
- For an example of reading options from option files, see [Section 5.7.4, “Using Client Programs in a Multiple-Server Environment”](#).
- For secure coding tips, see [Section 6.1.1, “Security Guidelines”](#).
- For debugging tips, see [Section 5.8.1.4, “Debugging mysqld under gdb”](#).
- For some Perl-specific environment variables, see [Section 4.9, “Environment Variables”](#).
- For considerations for running on macOS, see [Section 2.4, “Installing MySQL on macOS”](#).
- For ways to quote string literals, see [Section 9.1.1, “String Literals”](#).

DBI information is available at the command line, online, or in printed form:

- Once you have the `DBI` and `DBD::mysql` modules installed, you can get information about them at the command line with the `perldoc` command:

```
shell> perldoc DBI
shell> perldoc DBI::FAQ
shell> perldoc DBD::mysql
```

You can also use `pod2man`, `pod2html`, and so on to translate this information into other formats.

- For online information about Perl DBI, visit the DBI website, <http://dbi.perl.org/>. That site hosts a general DBI mailing list.
- For printed information, the official DBI book is *Programming the Perl DBI* (Alligator Descartes and Tim Bunce, O'Reilly & Associates, 2000). Information about the book is available at the DBI website, <http://dbi.perl.org/>.

## 27.10 MySQL Python API

[MySQLdb](#) is a third-party driver that provides MySQL support for Python, compliant with the Python DB API version 2.0. It can be found at <http://sourceforge.net/projects/mysql-python/>.

The new MySQL Connector/Python component provides an interface to the same Python API, and is built into the MySQL Server and supported by Oracle. See [MySQL Connector/Python Developer Guide](#) for details on the Connector, as well as coding guidelines for Python applications and sample Python code.

## 27.11 MySQL Ruby APIs

Two APIs are available for Ruby programmers developing MySQL applications:

- The MySQL/Ruby API is based on the `libmysqlclient` API library. For information on installing and using the MySQL/Ruby API, see [Section 27.11.1, “The MySQL/Ruby API”](#).
- The Ruby/MySQL API is written to use the native MySQL network protocol (a native driver). For information on installing and using the Ruby/MySQL API, see [Section 27.11.2, “The Ruby/MySQL API”](#).

For background and syntax information about the Ruby language, see [Ruby Programming Language](#).

### 27.11.1 The MySQL/Ruby API

The MySQL/Ruby module provides access to MySQL databases using Ruby through `libmysqlclient`.

For information on installing the module, and the functions exposed, see [MySQL/Ruby](#).

### 27.11.2 The Ruby/MySQL API

The Ruby/MySQL module provides access to MySQL databases using Ruby through a native driver interface using the MySQL network protocol.

For information on installing the module, and the functions exposed, see [Ruby/MySQL](#).

## 27.12 MySQL Tcl API

[MySQLtcl](#) is a simple API for accessing a MySQL database server from the [Tcl programming language](#). It can be found at <http://www.xdobry.de/mysqltcl/>.

## 27.13 MySQL Eiffel Wrapper

Eiffel MySQL is an interface to the MySQL database server using the [Eiffel programming language](#), written by Michael Ravits. It can be found at <http://efsa.sourceforge.net/archive/ravits/mysql.htm>.

| 28.8 MySQL Enterprise Data Masking and De-Identification Overview ..... | 4050 |

MySQL Enterprise Edition is a commercial product. Like MySQL Community Edition, MySQL Enterprise Edition includes MySQL Server, a fully integrated transaction-safe, ACID-compliant database with full commit, rollback, crash-recovery, and row-level locking capabilities. In addition, MySQL Enterprise Edition includes the following components designed to provide monitoring and online backup, as well as improved security and scalability:

The following sections briefly discuss each of these components and indicate where to find more detailed information. To learn more about commercial products, see <https://www.mysql.com/products/>.

- [MySQL Enterprise Monitor](#)
- [MySQL Enterprise Backup](#)
- [MySQL Enterprise Security](#)
- [MySQL Enterprise Encryption](#)
- [MySQL Enterprise Audit](#)
- [MySQL Enterprise Firewall](#)
- [MySQL Enterprise Thread Pool](#)
- [MySQL Enterprise Data Masking and De-Identification](#)

## 28.1 MySQL Enterprise Monitor Overview

MySQL Enterprise Monitor is an enterprise monitoring system for MySQL that keeps an eye on your MySQL servers, notifies you of potential issues and problems, and advises you how to fix the issues. MySQL Enterprise Monitor can monitor all kinds of configurations, from a single MySQL server that is important to your business, all the way up to a huge farm of MySQL servers powering a busy website.

The following discussion briefly summarizes the basic components that make up the MySQL Enterprise Monitor product. For more information, see the MySQL Enterprise Monitor manual, available at <https://dev.mysql.com/doc/mysql-monitor/en/>.

MySQL Enterprise Monitor components can be installed in various configurations depending on your database and network topology, to give you the best combination of reliable and responsive monitoring data, with minimal overhead on the database server machines. A typical MySQL Enterprise Monitor installation consists of:

- One or more MySQL servers to monitor. MySQL Enterprise Monitor can monitor both Community and Enterprise MySQL server releases.
- A MySQL Enterprise Monitor Agent for each monitored host.

- A single MySQL Enterprise Service Manager, which collates information from the agents and provides the user interface to the collected data.

MySQL Enterprise Monitor is designed to monitor one or more MySQL servers. The monitoring information is collected by using an agent, *MySQL Enterprise Monitor Agent*. The agent communicates with the hosts and MySQL servers that it monitors, collecting variables, status and health information, and sending this information to the MySQL Enterprise Service Manager.

The information collected by the agent about each MySQL server and host you are monitoring is sent to the *MySQL Enterprise Service Manager*. This server collates all of the information from the agents. As it collates the information sent by the agents, the MySQL Enterprise Service Manager continually tests the collected data, comparing the status of the server to reasonable values. When thresholds are reached, the server can trigger an event (including an alarm and notification) to highlight a potential issue, such as low memory, high CPU usage, or more complex conditions such insufficient buffer sizes and status information. We call each test, with its associated threshold value, a *rule*.

These rules, and the alarms and notifications, are each known as a *MySQL Enterprise Advisors*. Advisors form a critical part of the MySQL Enterprise Service Manager, as they provide warning information and troubleshooting advice about potential problems.

The MySQL Enterprise Service Manager includes a web server, and you interact with it through any web browser. This interface, the MySQL Enterprise Monitor User Interface, displays all of the information collected by the agents, and lets you view all of your servers and their current status as a group or individually. You control and configure all aspects of the service using the MySQL Enterprise Monitor User Interface.

The information supplied by the MySQL Enterprise Monitor Agent processes also includes statistical and query information, which you can view in the form of graphs. For example, you can view aspects such as server load, query numbers, or index usage information as a graph over time. The graph lets you pinpoint problems or potential issues on your server, and can help diagnose the impact from database or external problems (such as external system or network failure) by examining the data from a specific time interval.

The MySQL Enterprise Monitor Agent can also be configured to collect detailed information about the queries executed on your server, including the row counts and performance times for executing each query. You can correlate the detailed query data with the graphical information to identify which queries were executing when you experienced a particularly high load, index or other issue. The query data is supported by a system called Query Analyzer, and the data can be presented in different ways depending on your needs.

## 28.2 MySQL Enterprise Backup Overview

MySQL Enterprise Backup performs hot backup operations for MySQL databases. The product is architected for efficient and reliable backups of tables created by the InnoDB storage engine. For completeness, it can also back up tables from MyISAM and other storage engines.

The following discussion briefly summarizes MySQL Enterprise Backup. For more information, see the MySQL Enterprise Backup manual, available at <https://dev.mysql.com/doc/mysql-enterprise-backup/en/>.

Hot backups are performed while the database is running and applications are reading and writing to it. This type of backup does not block normal database operations, and it captures even changes that occur while the backup is happening. For these reasons, hot backups are desirable when your database “grows up” -- when the data is large enough that the backup takes significant time, and when your data is important enough to your business that you must capture every last change, without taking your application, website, or web service offline.

MySQL Enterprise Backup does a hot backup of all tables that use the InnoDB storage engine. For tables using MyISAM or other non-InnoDB storage engines, it does a “warm” backup, where the database continues to run, but those tables cannot be modified while being backed up. For efficient

backup operations, you can designate InnoDB as the default storage engine for new tables, or convert existing tables to use the InnoDB storage engine.

## 28.3 MySQL Enterprise Security Overview

MySQL Enterprise Edition provides plugins that implement security features using external services:

- MySQL Enterprise Edition includes an authentication plugin that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as Unix passwords or an LDAP directory. For more information, see [Section 6.4.1.7, “PAM Pluggable Authentication”](#).
- MySQL Enterprise Edition includes an authentication plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. For more information, see [Section 6.4.1.8, “Windows Pluggable Authentication”](#).
- MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable masking existing data using several methods such as obfuscation (removing identifying characteristics), generation of formatted random data, and data replacement or substitution. For more information, see [Section 28.4, “MySQL Enterprise Encryption Overview”](#).
- MySQL Enterprise Edition 5.7 and higher includes a keyring plugin that uses Oracle Key Vault as a back end for keyring storage. For more information, see [Section 6.4.4, “The MySQL Keyring”](#).

For other related Enterprise security features, see [Section 28.4, “MySQL Enterprise Encryption Overview”](#).

## 28.4 MySQL Enterprise Encryption Overview

MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

For more information, see [Section 6.6, “MySQL Enterprise Encryption”](#).

For other related Enterprise security features, see [Section 28.3, “MySQL Enterprise Security Overview”](#).

## 28.5 MySQL Enterprise Audit Overview

MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

For more information, see [Section 6.4.5, “MySQL Enterprise Audit”](#).

## 28.6 MySQL Enterprise Firewall Overview

MySQL Enterprise Edition includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against allowlists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.

Each MySQL account registered with the firewall has its own statement allowlist, enabling protection to be tailored per account. For a given account, the firewall can operate in recording or protecting mode, for training in the accepted statement patterns or protection against unacceptable statements.

For more information, see [Section 6.4.6, “MySQL Enterprise Firewall”](#).

## 28.7 MySQL Enterprise Thread Pool Overview

MySQL Enterprise Edition includes MySQL Enterprise Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. In MySQL Enterprise Edition, a thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

For more information, see [Section 5.5.3, “MySQL Enterprise Thread Pool”](#).

## 28.8 MySQL Enterprise Data Masking and De-Identification Overview

MySQL Enterprise Edition 5.7 and higher includes MySQL Enterprise Data Masking and De-Identification, implemented as a plugin library containing a plugin and a set of user-defined functions. Data masking hides sensitive information by replacing real values with substitutes. MySQL Enterprise Data Masking and De-Identification functions enable masking existing data using several methods such as obfuscation (removing identifying characteristics), generation of formatted random data, and data replacement or substitution.

For more information, see [Section 6.5, “MySQL Enterprise Data Masking and De-Identification”](#).

---

# Chapter 29 MySQL Workbench

MySQL Workbench provides a graphical tool for working with MySQL servers and databases. MySQL Workbench fully supports MySQL versions 5.5 and higher.

The following discussion briefly describes MySQL Workbench capabilities. For more information, see the MySQL Workbench manual, available at <https://dev.mysql.com/doc/workbench/en/>.

MySQL Workbench provides five main areas of functionality:

- **SQL Development:** Enables you to create and manage connections to database servers. As well as enabling you to configure connection parameters, MySQL Workbench provides the capability to execute SQL queries on the database connections using the built-in SQL Editor. This functionality replaces that previously provided by the Query Browser standalone application.
- **Data Modeling:** Enables you to create models of your database schema graphically, reverse and forward engineer between a schema and a live database, and edit all aspects of your database using the comprehensive Table Editor. The Table Editor provides easy-to-use facilities for editing Tables, Columns, Indexes, Triggers, Partitioning, Options, Inserts and Privileges, Routines and Views.
- **Server Administration:** Enables you to create and administer server instances.
- **Data Migration:** Allows you to migrate from Microsoft SQL Server, Sybase ASE, SQLite, SQL Anywhere, PostgreSQL, and other RDBMS tables, objects and data to MySQL. Migration also supports migrating from earlier versions of MySQL to the latest releases.
- **MySQL Enterprise Support:** Support for Enterprise products such as MySQL Enterprise Backup and MySQL Audit.

MySQL Workbench is available in two editions, the Community Edition and the Commercial Edition. The Community Edition is available free of charge. The Commercial Edition provides additional Enterprise features, such as database documentation generation, at low cost.

---

### A.1.1. Which version of MySQL is production-ready (GA)?

MySQL 8.0, 5.7, and MySQL 5.6 are supported for production use.

MySQL 8.0 achieved General Availability (GA) status with MySQL 8.0.11, which was released for production use on 19 April 2018.

MySQL 5.7 achieved General Availability (GA) status with MySQL 5.7.9, which was released for production use on 21 October 2015.

MySQL 5.6 achieved General Availability (GA) status with MySQL 5.6.10, which was released for production use on 5 February 2013.

MySQL 5.5 achieved General Availability (GA) status with MySQL 5.5.8, which was released for production use on 3 December 2010. Active development for MySQL 5.5 has ended.

MySQL 5.1 achieved General Availability (GA) status with MySQL 5.1.30, which was released for production use on 14 November 2008. Active development for MySQL 5.1 has ended.

MySQL 5.0 achieved General Availability (GA) status with MySQL 5.0.15, which was released for production use on 19 October 2005. Active development for MySQL 5.0 has ended.

**A.1.2.** Can MySQL 5.7 do subqueries?

Yes. See [Section 13.2.10, “Subqueries”](#).

**A.1.3.** Can MySQL 5.7 perform multiple-table inserts, updates, and deletes?

Yes. For the syntax required to perform multiple-table updates, see [Section 13.2.11, “UPDATE Statement”](#); for that required to perform multiple-table deletes, see [Section 13.2.2, “DELETE Statement”](#).

A multiple-table insert can be accomplished using a trigger whose `FOR EACH ROW` clause contains multiple `INSERT` statements within a `BEGIN ... END` block. See [Section 23.3, “Using Triggers”](#).

**A.1.4.** Does MySQL 5.7 have a Query Cache? Does it work on Server, Instance or Database?

Yes. (However, the query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0.) The query cache operates on the server level, caching complete result sets matched with the original query string. If an exactly identical query is made (which often happens, particularly in web applications), no parsing or execution is necessary; the result is sent directly from the cache. Various tuning options are available. See [Section 8.10.3, “The MySQL Query Cache”](#).

**A.1.5.** Does MySQL 5.7 have Sequences?

No. However, MySQL has an `AUTO_INCREMENT` system, which in MySQL 5.7 can also handle inserts in a multi-source replication setup. With the `auto_increment_increment` and `auto_increment_offset` system variables, you can set each server to generate auto-increment values that don't conflict with other servers. The `auto_increment_increment` value should be greater than the number of servers, and each server should have a unique offset.

**A.1.6.** Does MySQL 5.7 have a `NOW( )` function with fractions of seconds?

Yes, see [Section 11.2.7, “Fractional Seconds in Time Values”](#).

**A.1.7.** Does MySQL 5.7 work with multi-core processors?

Yes. MySQL is fully multithreaded, and makes use of all CPUs made available to it. Not all CPUs may be available; modern operating systems should be able to utilize all underlying CPUs, but also make it possible to restrict a process to a specific CPU or sets of CPUs.

On Windows, there is currently a limit to the number of (logical) processors that `mysqld` can use: a single processor group, which is limited to a maximum of 64 logical processors.

Use of multiple cores may be seen in these ways:

- A single core is usually used to service the commands issued from one session.
- A few background threads make limited use of extra cores; for example, to keep background I/O tasks moving.
- If the database is I/O-bound (indicated by CPU consumption less than capacity), adding more CPUs is futile. If the database is partitioned into an I/O-bound part and a CPU-bound part, adding CPUs may still be useful.

**A.1.8.** Why do I see multiple processes for `mysqld`?

`mysqld` is a single-process program, not a multi-process program, and does not fork or launch other processes. However, `mysqld` is multithreaded and some process-reporting system utilities display separate entries for each thread of multithreaded processes, which may lead to the appearance of multiple `mysqld` processes when in fact there is only one.

**A.1.9.** Can MySQL 5.7 perform ACID transactions?

Yes. All current MySQL versions support transactions. The [InnoDB](#) storage engine offers full ACID transactions with row-level locking, multi-versioning, nonlocking repeatable reads, and all four SQL standard isolation levels.

The [NDB](#) storage engine supports the [READ COMMITTED](#) transaction isolation level only.

## A.2 MySQL 5.7 FAQ: Storage Engines

|                                                                                                                                                                                                          |      |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| A.2.1 Where can I obtain complete documentation for MySQL storage engines? .....                                                                                                                         | 4055 |
| A.2.2 Are there any new storage engines in MySQL 5.7? .....                                                                                                                                              | 4055 |
| A.2.3 Have any storage engines been removed in MySQL 5.7? .....                                                                                                                                          | 4055 |
| A.2.4 Can I prevent the use of a particular storage engine? .....                                                                                                                                        | 4055 |
| A.2.5 Is there an advantage to using the <a href="#">InnoDB</a> storage engine exclusively, as opposed to a combination of <a href="#">InnoDB</a> and non- <a href="#">InnoDB</a> storage engines? ..... | 4055 |
| A.2.6 What are the unique benefits of the <a href="#">ARCHIVE</a> storage engine? .....                                                                                                                  | 4055 |

**A.2.1.** Where can I obtain complete documentation for MySQL storage engines?

See [Chapter 15, Alternative Storage Engines](#). That chapter contains information about all MySQL storage engines except for the [InnoDB](#) storage engine and the [NDB](#) storage engine (used for MySQL Cluster). [InnoDB](#) is covered in [Chapter 14, The InnoDB Storage Engine](#). [NDB](#) is covered in [Chapter 21, MySQL NDB Cluster 7.5 and NDB Cluster 7.6](#).

**A.2.2.** Are there any new storage engines in MySQL 5.7?

No. [InnoDB](#) is the default storage engine for new tables. See [Section 14.1, “Introduction to InnoDB”](#) for details.

**A.2.3.** Have any storage engines been removed in MySQL 5.7?

No.

**A.2.4.** Can I prevent the use of a particular storage engine?

Yes. The [disabled\\_storage\\_engines](#) configuration option defines which storage engines cannot be used to create tables or tablespaces. By default, [disabled\\_storage\\_engines](#) is empty (no engines disabled), but it can be set to a comma-separated list of one or more engines.

**A.2.5.** Is there an advantage to using the [InnoDB](#) storage engine exclusively, as opposed to a combination of [InnoDB](#) and non-[InnoDB](#) storage engines?

Yes. Using [InnoDB](#) tables exclusively can simplify backup and recovery operations. MySQL Enterprise Backup does a [hot backup](#) of all tables that use the [InnoDB](#) storage engine. For tables using [MyISAM](#) or other non-[InnoDB](#) storage engines, it does a “warm” backup, where the database continues to run, but those tables cannot be modified while being backed up. See [Section 28.2, “MySQL Enterprise Backup Overview”](#).

**A.2.6.** What are the unique benefits of the [ARCHIVE](#) storage engine?

The [ARCHIVE](#) storage engine stores large amounts of data without indexes; it has a small footprint, and performs selects using table scans. See [Section 15.5, “The ARCHIVE Storage Engine”](#), for details.

## A.3 MySQL 5.7 FAQ: Server SQL Mode

|                                                       |      |
|-------------------------------------------------------|------|
| A.3.1 What are server SQL modes? .....                | 4056 |
| A.3.2 How many server SQL modes are there? .....      | 4056 |
| A.3.3 How do you determine the server SQL mode? ..... | 4056 |

|                                                                              |      |
|------------------------------------------------------------------------------|------|
| A.3.4 Is the mode dependent on the database or connection? .....             | 4056 |
| A.3.5 Can the rules for strict mode be extended? .....                       | 4056 |
| A.3.6 Does strict mode impact performance? .....                             | 4056 |
| A.3.7 What is the default server SQL mode when MySQL 5.7 is installed? ..... | 4056 |

### A.3.1. What are server SQL modes?

Server SQL modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers. The MySQL Server apply these modes individually to different clients. For more information, see [Section 5.1.10, “Server SQL Modes”](#).

### A.3.2. How many server SQL modes are there?

Each mode can be independently switched on and off. See [Section 5.1.10, “Server SQL Modes”](#), for a complete list of available modes.

### A.3.3. How do you determine the server SQL mode?

You can set the default SQL mode (for `mysqld` startup) with the `--sql-mode` option. Using the statement `SET [GLOBAL|SESSION] sql_mode='modes'`, you can change the settings from within a connection, either locally to the connection, or to take effect globally. You can retrieve the current mode by issuing a `SELECT @@sql_mode` statement.

### A.3.4. Is the mode dependent on the database or connection?

A mode is not linked to a particular database. Modes can be set locally to the session (connection), or globally for the server. you can change these settings using `SET [GLOBAL|SESSION] sql_mode='modes'`.

### A.3.5. Can the rules for strict mode be extended?

When we refer to *strict mode*, we mean a mode where at least one of the modes `TRADITIONAL`, `STRICT_TRANS_TABLES`, or `STRICT_ALL_TABLES` is enabled. Options can be combined, so you can add restrictions to a mode. See [Section 5.1.10, “Server SQL Modes”](#), for more information.

### A.3.6. Does strict mode impact performance?

The intensive validation of input data that some settings requires more time than if the validation is not done. While the performance impact is not that great, if you do not require such validation (perhaps your application already handles all of this), then MySQL gives you the option of leaving strict mode disabled. However, if you do require it, strict mode can provide such validation.

### A.3.7. What is the default server SQL mode when MySQL 5.7 is installed?

The default SQL mode in MySQL 5.7 includes these modes: `ONLY_FULL_GROUP_BY`, `STRICT_TRANS_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, `NO_AUTO_CREATE_USER`, and `NO_ENGINE_SUBSTITUTION`.

For information about all available modes and default MySQL behavior, see [Section 5.1.10, “Server SQL Modes”](#).

## A.4 MySQL 5.7 FAQ: Stored Procedures and Functions

|                                                                                              |      |
|----------------------------------------------------------------------------------------------|------|
| A.4.1 Does MySQL 5.7 support stored procedures and functions? .....                          | 4057 |
| A.4.2 Where can I find documentation for MySQL stored procedures and stored functions? ..... | 4057 |
| A.4.3 Is there a discussion forum for MySQL stored procedures? .....                         | 4057 |

|                                                                                                                                                         |      |
|---------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| A.4.4 Where can I find the ANSI SQL 2003 specification for stored procedures? .....                                                                     | 4057 |
| A.4.5 How do you manage stored routines? .....                                                                                                          | 4057 |
| A.4.6 Is there a way to view all stored procedures and stored functions in a given database? .....                                                      | 4057 |
| A.4.7 Where are stored procedures stored? .....                                                                                                         | 4058 |
| A.4.8 Is it possible to group stored procedures or stored functions into packages? .....                                                                | 4058 |
| A.4.9 Can a stored procedure call another stored procedure? .....                                                                                       | 4058 |
| A.4.10 Can a stored procedure call a trigger? .....                                                                                                     | 4058 |
| A.4.11 Can a stored procedure access tables? .....                                                                                                      | 4058 |
| A.4.12 Do stored procedures have a statement for raising application errors? .....                                                                      | 4058 |
| A.4.13 Do stored procedures provide exception handling? .....                                                                                           | 4058 |
| A.4.14 Can MySQL 5.7 stored routines return result sets? .....                                                                                          | 4058 |
| A.4.15 Is <code>WITH RECOMPILE</code> supported for stored procedures? .....                                                                            | 4058 |
| A.4.16 Is there a MySQL equivalent to using <code>mod_plsql</code> as a gateway on Apache to talk directly to a stored procedure in the database? ..... | 4058 |
| A.4.17 Can I pass an array as input to a stored procedure? .....                                                                                        | 4059 |
| A.4.18 Can I pass a cursor as an <code>IN</code> parameter to a stored procedure? .....                                                                 | 4059 |
| A.4.19 Can I return a cursor as an <code>OUT</code> parameter from a stored procedure? .....                                                            | 4059 |
| A.4.20 Can I print out a variable's value within a stored routine for debugging purposes? .....                                                         | 4059 |
| A.4.21 Can I commit or roll back transactions inside a stored procedure? .....                                                                          | 4059 |
| A.4.22 Do MySQL 5.7 stored procedures and functions work with replication? .....                                                                        | 4059 |
| A.4.23 Are stored procedures and functions created on a replication source server replicated to a replica? .....                                        | 4059 |
| A.4.24 How are actions that take place inside stored procedures and functions replicated? .....                                                         | 4059 |

| A.4.27 Do the preceding limitations affect the ability of MySQL to do point-in-time recovery? .....                                                     | 4060 |
| A.4.28 What is being done to correct the aforementioned limitations? .....                                                                              | 4060 |

**A.4.1.** Does MySQL 5.7 support stored procedures and functions?

Yes. MySQL 5.7 supports two types of stored routines, stored procedures and stored functions.

**A.4.2.** Where can I find documentation for MySQL stored procedures and stored functions?

See [Section 23.2, “Using Stored Routines”](#).

**A.4.3.** Is there a discussion forum for MySQL stored procedures?

Yes. See <https://forums.mysql.com/list.php?98>.

**A.4.4.** Where can I find the ANSI SQL 2003 specification for stored procedures?

Unfortunately, the official specifications are not freely available (ANSI makes them available for purchase). However, there are books, such as *SQL-99 Complete, Really* by Peter Gulutzan and Trudy Pelzer, that provide a comprehensive overview of the standard, including coverage of stored procedures.

**A.4.5.** How do you manage stored routines?

It is always good practice to use a clear naming scheme for your stored routines. You can manage stored procedures with `CREATE [FUNCTION|PROCEDURE]`, `ALTER [FUNCTION|PROCEDURE]`, `DROP [FUNCTION|PROCEDURE]`, and `SHOW CREATE [FUNCTION|PROCEDURE]`. You can obtain information about existing stored procedures using the `ROUTINES` table in the `INFORMATION_SCHEMA` database (see [Section 24.3.21, “The INFORMATION\\_SCHEMA ROUTINES Table”](#)).

**A.4.6.** Is there a way to view all stored procedures and stored functions in a given database?

Yes. For a database named `dbname`, use this query on the `INFORMATION_SCHEMA.ROUTINES` table:

```
SELECT ROUTINE_TYPE, ROUTINE_NAME
 FROM INFORMATION_SCHEMA.ROUTINES
 WHERE ROUTINE_SCHEMA='dbname';
```

For more information, see [Section 24.3.21, “The INFORMATION\\_SCHEMA ROUTINES Table”](#).

The body of a stored routine can be viewed using `SHOW CREATE FUNCTION` (for a stored function) or `SHOW CREATE PROCEDURE` (for a stored procedure). See [Section 13.7.5.9, “SHOW CREATE PROCEDURE Statement”](#), for more information.

#### A.4.7. Where are stored procedures stored?

In the `proc` table of the `mysql` system database. However, you should not access the tables in the system database directly. Instead, query the `INFORMATION_SCHEMA ROUTINES` and `PARAMETERS` tables. See [Section 24.3.21, “The INFORMATION\\_SCHEMA ROUTINES Table”](#), and [Section 24.3.15, “The INFORMATION\\_SCHEMA PARAMETERS Table”](#).

You can also use `SHOW CREATE FUNCTION` to obtain information about stored functions, and `SHOW CREATE PROCEDURE` to obtain information about stored procedures. See [Section 13.7.5.9, “SHOW CREATE PROCEDURE Statement”](#).

#### A.4.8. Is it possible to group stored procedures or stored functions into packages?

No. This is not supported in MySQL 5.7.

#### A.4.9. Can a stored procedure call another stored procedure?

Yes.

#### A.4.10 Can a stored procedure call a trigger?

A stored procedure can execute an SQL statement, such as an `UPDATE`, that causes a trigger to activate.

#### A.4.11 Can a stored procedure access tables?

Yes. A stored procedure can access one or more tables as required.

#### A.4.12 Do stored procedures have a statement for raising application errors?

Yes. MySQL 5.7 implements the SQL standard `SIGNAL` and `RESIGNAL` statements. See [Section 13.6.7, “Condition Handling”](#).

#### A.4.13 Do stored procedures provide exception handling?

MySQL implements `HANDLER` definitions according to the SQL standard. See [Section 13.6.7.2, “DECLARE ... HANDLER Statement”](#), for details.

#### A.4.14 Can MySQL 5.7 stored routines return result sets?

*Stored procedures* can, but stored functions cannot. If you perform an ordinary `SELECT` inside a stored procedure, the result set is returned directly to the client. You need to use the MySQL 4.1 (or higher) client/server protocol for this to work. This means that, for example, in PHP, you need to use the `mysqli` extension rather than the old `mysql` extension.

#### A.4.15 Is `WITH RECOMPILE` supported for stored procedures?

Not in MySQL 5.7.

#### A.4.16 Is there a MySQL equivalent to using `mod_plsql` as a gateway on Apache to talk directly to a stored procedure in the database?

There is no equivalent in MySQL 5.7.

**A.4.17**Can I pass an array as input to a stored procedure?

Not in MySQL 5.7.

**A.4.18**Can I pass a cursor as an `IN` parameter to a stored procedure?

In MySQL 5.7, cursors are available inside stored procedures only.

**A.4.19**Can I return a cursor as an `OUT` parameter from a stored procedure?

In MySQL 5.7, cursors are available inside stored procedures only. However, if you do not open a cursor on a `SELECT`, the result is sent directly to the client. You can also `SELECT INTO` variables. See [Section 13.2.9, “SELECT Statement”](#).

**A.4.20**Can I print out a variable's value within a stored routine for debugging purposes?

Yes, you can do this in a *stored procedure*, but not in a stored function. If you perform an ordinary `SELECT` inside a stored procedure, the result set is returned directly to the client. You must use the MySQL 4.1 (or above) client/server protocol for this to work. This means that, for example, in PHP, you need to use the `mysqli` extension rather than the old `mysql` extension.

**A.4.21**Can I commit or roll back transactions inside a stored procedure?

Yes. However, you cannot perform transactional operations within a stored function.

**A.4.22**Do MySQL 5.7 stored procedures and functions work with replication?

Yes, standard actions carried out in stored procedures and functions are replicated from a replication source server to a replica. There are a few limitations that are described in detail in [Section 23.7, “Stored Program Binary Logging”](#).

**A.4.23**Are stored procedures and functions created on a replication source server replicated to a replica?

Yes, creation of stored procedures and functions carried out through normal DDL statements on a replication source server are replicated to a replica, so that the objects exist on both servers. `ALTER` and `DROP` statements for stored procedures and functions are also replicated.

**A.4.24**How are actions that take place inside stored procedures and functions replicated?

MySQL records each DML event that occurs in a stored procedure and replicates those individual actions to a replica. The actual calls made to execute stored procedures are not replicated.

Stored functions that change data are logged as function invocations, not as the DML events that occur inside each function.

**A.4.25**Are there special security requirements for using stored procedures and functions together with replication?

Yes. Because a replica has authority to execute any statement read from a source's binary log, special security constraints exist for using stored functions with replication. If replication or binary logging in general (for the purpose of point-in-time recovery) is active, then MySQL DBAs have two security options open to them:

1. Any user wishing to create stored functions must be granted the `SUPER` privilege.
2. Alternatively, a DBA can set the `log_bin_trust_function_creators` system variable to 1, which enables anyone with the standard `CREATE ROUTINE` privilege to create stored functions.

**A.4.26**What limitations exist for replicating stored procedure and function actions?

Nondeterministic (random) or time-based actions embedded in stored procedures may not replicate properly. By their very nature, randomly produced results are not predictable and cannot be exactly reproduced; therefore, random actions replicated to a replica do not mirror those performed on a source. Declaring stored functions to be `DETERMINISTIC` or setting the `log_bin_trust_function_creators` system variable to 0 keeps random operations producing random values from being invoked.

In addition, time-based actions cannot be reproduced on a replica because the timing of such actions in a stored procedure is not reproducible through the binary log used for replication. It records only DML events and does not factor in timing constraints.

Finally, nontransactional tables for which errors occur during large DML actions (such as bulk inserts) may experience replication issues in that a source may be partially updated from DML activity, but no updates are done to the replica because of the errors that occurred. A workaround is for a function's DML actions to be carried out with the `IGNORE` keyword so that updates on the source that cause errors are ignored and updates that do not cause errors are replicated to the replica.

#### A.4.27 Do the preceding limitations affect the ability of MySQL to do point-in-time recovery?

The same limitations that affect replication do affect point-in-time recovery.

#### A.4.28 What is being done to correct the aforementioned limitations?

You can choose either statement-based replication or row-based replication. The original replication implementation is based on statement-based binary logging. Row-based binary logging resolves the limitations mentioned earlier.

Mixed replication is also available (by starting the server with `--binlog-format=mixed`). This hybrid form of replication “knows” whether statement-level replication can safely be used, or row-level replication is required.

For additional information, see [Section 16.2.1, “Replication Formats”](#).

## A.5 MySQL 5.7 FAQ: Triggers

|                                                                                                |      |
|------------------------------------------------------------------------------------------------|------|
| A.5.1 Where can I find the documentation for MySQL 5.7 triggers? .....                         | 4060 |
| A.5.2 Is there a discussion forum for MySQL Triggers? .....                                    | 4060 |
| A.5.3 Does MySQL 5.7 have statement-level or row-level triggers? .....                         | 4060 |
| A.5.4 Are there any default triggers? .....                                                    | 4061 |
| A.5.5 How are triggers managed in MySQL? .....                                                 | 4061 |
| A.5.6 Is there a way to view all triggers in a given database? .....                           | 4061 |
| A.5.7 Where are triggers stored? .....                                                         | 4061 |
| A.5.8 Can a trigger call a stored procedure? .....                                             | 4061 |
| A.5.9 Can triggers access tables? .....                                                        | 4061 |
| A.5.10 Can a table have multiple triggers with the same trigger event and action time? .....   | 4061 |
| A.5.11 Can triggers call an external application through a UDF? .....                          | 4061 |
| A.5.12 Is it possible for a trigger to update tables on a remote server? .....                 | 4061 |
| A.5.13 Do triggers work with replication? .....                                                | 4062 |
| A.5.14 How are actions carried out through triggers on a source replicated to a replica? ..... | 4062 |

#### A.5.1. Where can I find the documentation for MySQL 5.7 triggers?

See [Section 23.3, “Using Triggers”](#).

#### A.5.2. Is there a discussion forum for MySQL Triggers?

Yes. It is available at <https://forums.mysql.com/list.php?99>.

#### A.5.3. Does MySQL 5.7 have statement-level or row-level triggers?

In MySQL 5.7, all triggers are `FOR EACH ROW`; that is, the trigger is activated for each row that is inserted, updated, or deleted. MySQL 5.7 does not support triggers using `FOR EACH STATEMENT`.

#### A.5.4. Are there any default triggers?

Not explicitly. MySQL does have specific special behavior for some `TIMESTAMP` columns, as well as for columns which are defined using `AUTO_INCREMENT`.

#### A.5.5. How are triggers managed in MySQL?

In MySQL 5.7, triggers can be created using the `CREATE TRIGGER` statement, and dropped using `DROP TRIGGER`. See [Section 13.1.20, “CREATE TRIGGER Statement”](#), and [Section 13.1.31, “DROP TRIGGER Statement”](#), for more about these statements.

Information about triggers can be obtained by querying the `INFORMATION_SCHEMA.TRIGGERS` table. See [Section 24.3.29, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).

#### A.5.6. Is there a way to view all triggers in a given database?

Yes. You can obtain a listing of all triggers defined on database `dbname` using a query on the `INFORMATION_SCHEMA.TRIGGERS` table such as the one shown here:

```
SELECT TRIGGER_NAME, EVENT_MANIPULATION, EVENT_OBJECT_TABLE, ACTION_STATEMENT
 FROM INFORMATION_SCHEMA.TRIGGERS
 WHERE TRIGGER_SCHEMA= 'dbname' ;
```

For more information about this table, see [Section 24.3.29, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).

You can also use the `SHOW TRIGGERS` statement, which is specific to MySQL. See [Section 13.7.5.38, “SHOW TRIGGERS Statement”](#).

#### A.5.7. Where are triggers stored?

Triggers are stored in `.TRG` files, with one such file one per table.

#### A.5.8. Can a trigger call a stored procedure?

Yes.

#### A.5.9. Can triggers access tables?

A trigger can access both old and new data in its own table. A trigger can also affect other tables, but it is not permitted to modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.

#### A.5.10. Can a table have multiple triggers with the same trigger event and action time?

It is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two `BEFORE UPDATE` triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a clause after `FOR EACH ROW` that indicates `FOLLOWS` or `PRECEDES` and the name of an existing trigger that also has the same trigger event and action time. With `FOLLOWS`, the new trigger activates after the existing trigger. With `PRECEDES`, the new trigger activates before the existing trigger.

#### A.5.11. Can triggers call an external application through a UDF?

Yes. For example, a trigger could invoke the `sys_exec()` UDF.

#### A.5.12. Is it possible for a trigger to update tables on a remote server?

Yes. A table on a remote server could be updated using the `FEDERATED` storage engine. (See [Section 15.8, “The FEDERATED Storage Engine”](#)).

#### A.5.13 Do triggers work with replication?

Yes. However, the way in which they work depends whether you are using MySQL's "classic" statement-based or row-based replication format.

When using statement-based replication, triggers on the replica are executed by statements that are executed on the source (and replicated to the replica).

When using row-based replication, triggers are not executed on the replica due to statements that were run on the source and then replicated to the replica. Instead, when using row-based replication, the changes caused by executing the trigger on the source are applied on the replica.

For more information, see [Section 16.4.1.34, "Replication and Triggers"](#).

#### A.5.14 How are actions carried out through triggers on a source replicated to a replica?

Again, this depends on whether you are using statement-based or row-based replication.

**Statement-based replication.** First, the triggers that exist on a source must be re-created on the replica server. Once this is done, the replication flow works as any other standard DML statement that participates in replication. For example, consider a table `EMP` that has an `AFTER` insert trigger, which exists on a replication source server. The same `EMP` table and `AFTER` insert trigger exist on the replica server as well. The replication flow would be:

1. An `INSERT` statement is made to `EMP`.
2. The `AFTER` trigger on `EMP` activates.
3. The `INSERT` statement is written to the binary log.
4. The replica picks up the `INSERT` statement to `EMP` and executes it.
5. The `AFTER` trigger on `EMP` that exists on the replica activates.

**Row-based replication.** When you use row-based replication, the changes caused by executing the trigger on the source are applied on the replica. However, the triggers themselves are not actually executed on the replica under row-based replication. This is because, if both the source and the replica applied the changes from the source and, in addition, the trigger causing these changes were applied on the replica, the changes would in effect be applied twice on the replica, leading to different data on the source and the replica.

In most cases, the outcome is the same for both row-based and statement-based replication. However, if you use different triggers on the source and replica, you cannot use row-based replication. (This is because the row-based format replicates the changes made by triggers executing on the source to the replicas, rather than the statements that caused the triggers to execute, and the corresponding triggers on the replica are not executed.) Instead, any statements causing such triggers to be executed must be replicated using statement-based replication.

For more information, see [Section 16.4.1.34, "Replication and Triggers"](#).

### A.6 MySQL 5.7 FAQ: Views

|                                                                                  |      |
|----------------------------------------------------------------------------------|------|
| A.6.1 Where can I find documentation covering MySQL Views? .....                 | 4063 |
| A.6.2 Is there a discussion forum for MySQL Views? .....                         | 4063 |
| A.6.3 What happens to a view if an underlying table is dropped or renamed? ..... | 4063 |
| A.6.4 Does MySQL 5.7 have table snapshots? .....                                 | 4063 |
| A.6.5 Does MySQL 5.7 have materialized views? .....                              | 4063 |
| A.6.6 Can you insert into views that are based on joins? .....                   | 4063 |

**A.6.1.** Where can I find documentation covering MySQL Views?

See [Section 23.5, “Using Views”](#).

**A.6.2.** Is there a discussion forum for MySQL Views?

Yes. See <https://forums.mysql.com/list.php?100>

**A.6.3.** What happens to a view if an underlying table is dropped or renamed?

After a view has been created, it is possible to drop or alter a table or view to which the definition refers. To check a view definition for problems of this kind, use the `CHECK TABLE` statement. (See [Section 13.7.2.2, “CHECK TABLE Statement”](#).)

**A.6.4.** Does MySQL 5.7 have table snapshots?

No.

**A.6.5.** Does MySQL 5.7 have materialized views?

No.

**A.6.6.** Can you insert into views that are based on joins?

It is possible, provided that your `INSERT` statement has a column list that makes it clear there is only one table involved.

You *cannot* insert into multiple tables with a single insert on a view.

## A.7 MySQL 5.7 FAQ: INFORMATION\_SCHEMA

|                                                                                                                   |      |
|-------------------------------------------------------------------------------------------------------------------|------|
| A.7.1 Where can I find documentation for the MySQL <code>INFORMATION_SCHEMA</code> database? .....                | 4063 |
| A.7.2 Is there a discussion forum for <code>INFORMATION_SCHEMA</code> ? .....                                     | 4063 |
| A.7.3 Where can I find the ANSI SQL 2003 specification for <code>INFORMATION_SCHEMA</code> ? .....                | 4063 |
| A.7.4 What is the difference between the Oracle Data Dictionary and MySQL <code>INFORMATION_SCHEMA</code> ? ..... | 4063 |
| A.7.5 Can I add to or otherwise modify the tables found in the <code>INFORMATION_SCHEMA</code> database? .....    | 4063 |

**A.7.1.** Where can I find documentation for the MySQL `INFORMATION_SCHEMA` database?

See [Chapter 24, \*INFORMATION\\_SCHEMA Tables\*](#)

**A.7.2.** Is there a discussion forum for `INFORMATION_SCHEMA`?

See <https://forums.mysql.com/list.php?101>.

**A.7.3.** Where can I find the ANSI SQL 2003 specification for `INFORMATION_SCHEMA`?

Unfortunately, the official specifications are not freely available. (ANSI makes them available for purchase.) However, there are books available, such as *SQL-99 Complete, Really* by Peter Gulutzan and Trudy Pelzer, that provide a comprehensive overview of the standard, including `INFORMATION_SCHEMA`.

**A.7.4.** What is the difference between the Oracle Data Dictionary and MySQL `INFORMATION_SCHEMA`?

Both Oracle and MySQL provide metadata in tables. However, Oracle and MySQL use different table names and column names. The MySQL implementation is more similar to those found in DB2 and SQL Server, which also support `INFORMATION_SCHEMA` as defined in the SQL standard.

**A.7.5.** Can I add to or otherwise modify the tables found in the `INFORMATION_SCHEMA` database?

No. Since applications may rely on a certain standard structure, this should not be modified. For this reason, we *cannot support bugs or other issues which result from modifying INFORMATION\_SCHEMA tables or data*.

## A.8 MySQL 5.7 FAQ: Migration

|                                                                                                      |      |
|------------------------------------------------------------------------------------------------------|------|
| A.8.1 Where can I find information on how to migrate from MySQL 5.6 to MySQL 5.7? .....              | 4064 |
| A.8.2 How has storage engine (table type) support changed in MySQL 5.7 from previous versions? ..... | 4064 |

### A.8.1. Where can I find information on how to migrate from MySQL 5.6 to MySQL 5.7?

For detailed upgrade information, see [Section 2.11, “Upgrading MySQL”](#). Do not skip a major version when upgrading, but rather complete the process in steps, upgrading from one major version to the next in each step. This may seem more complicated, but ultimately saves time and trouble. If you encounter problems during the upgrade, their origin is easier to identify, either by you or, if you have a MySQL Enterprise subscription, by MySQL support.

### A.8.2. How has storage engine (table type) support changed in MySQL 5.7 from previous versions?

Storage engine support has changed as follows:

- Support for [ISAM](#) tables was removed in MySQL 5.0 and you should now use the [MyISAM](#) storage engine in place of [ISAM](#). To convert a table `tblname` from [ISAM](#) to [MyISAM](#), simply issue a statement such as this one:

```
ALTER TABLE tblname ENGINE=MYISAM;
```

- Internal [RAID](#) for [MyISAM](#) tables was also removed in MySQL 5.0. This was formerly used to allow large tables in file systems that did not support file sizes greater than 2GB. All modern file systems allow for larger tables; in addition, there are now other solutions such as [MERGE](#) tables and views.
- The [VARCHAR](#) column type now retains trailing spaces in all storage engines.
- [MEMORY](#) tables (formerly known as [HEAP](#) tables) can also contain [VARCHAR](#) columns.

## A.9 MySQL 5.7 FAQ: Security

|                                                                                                           |      |
|-----------------------------------------------------------------------------------------------------------|------|
| A.9.1 Where can I find documentation that addresses security issues for MySQL? .....                      | 4064 |
| A.9.2 What is the default authentication plugin in MySQL 5.7? .....                                       | 4065 |
| A.9.3 Does MySQL 5.7 have native support for SSL? .....                                                   | 4065 |
| A.9.4 Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it? ..... | 4065 |
| A.9.5 Does MySQL 5.7 have built-in authentication against LDAP directories? .....                         | 4065 |
| A.9.6 Does MySQL 5.7 include support for Roles Based Access Control (RBAC)? .....                         | 4065 |

### A.9.1. Where can I find documentation that addresses security issues for MySQL?

The best place to start is [Chapter 6, Security](#).

Other portions of the MySQL Documentation which you may find useful with regard to specific security concerns include the following:

- [Section 6.1.1, “Security Guidelines”](#).
- [Section 6.1.3, “Making MySQL Secure Against Attackers”](#).
- [Section B.3.3.2, “How to Reset the Root Password”](#).
- [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

- [UDF Security Precautions](#).
- [Section 6.1.4, “Security-Related mysqld Options and Variables”](#).
- [Section 6.1.6, “Security Considerations for LOAD DATA LOCAL”](#).
- [Section 2.10, “Postinstallation Setup and Testing”](#).
- [Section 6.3, “Using Encrypted Connections”](#).

There is also the [Secure Deployment Guide](#), which provides procedures for deploying a generic binary distribution of MySQL Enterprise Edition Server with features for managing the security of your MySQL installation.

#### A.9.2. What is the default authentication plugin in MySQL 5.7?

The default authentication plugin in MySQL 5.7 is `mysql_native_password`. For information about this plugin, see [Section 6.4.1.1, “Native Pluggable Authentication”](#). For general information about pluggable authentication and other available authentication plugins, see [Section 6.2.13, “Pluggable Authentication”](#), and [Section 6.4.1, “Authentication Plugins”](#).

#### A.9.3. Does MySQL 5.7 have native support for SSL?

Most 5.7 binaries have support for SSL connections between the client and server. See [Section 6.3, “Using Encrypted Connections”](#).

You can also tunnel a connection using SSH, if (for example) the client application does not support SSL connections. For an example, see [Section 6.3.5, “Connecting to MySQL Remotely from Windows with SSH”](#).

#### A.9.4. Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it?

Most 5.7 binaries have SSL enabled for client/server connections that are secured, authenticated, or both. See [Section 6.3, “Using Encrypted Connections”](#).

#### A.9.5. Does MySQL 5.7 have built-in authentication against LDAP directories?

The Enterprise edition includes a [PAM Authentication Plugin](#) that supports authentication against an LDAP directory.

#### A.9.6. Does MySQL 5.7 include support for Roles Based Access Control (RBAC)?

Not at this time.

## A.10 MySQL 5.7 FAQ: NDB Cluster

In the following section, we answer questions that are frequently asked about NDB Cluster and the [NDB](#) storage engine.

|                                                                                                                                          |      |
|------------------------------------------------------------------------------------------------------------------------------------------|------|
| A.10.1 Which versions of the MySQL software support NDB Cluster? Do I have to compile from source? .....                                 | 4066 |
| A.10.2 What do “NDB” and “NDBCLUSTER” mean? .....                                                                                        | 4067 |
| A.10.3 What is the difference between using NDB Cluster versus using MySQL Replication? .....                                            | 4067 |
| A.10.4 Do I need any special networking to run NDB Cluster? How do computers in a cluster communicate? .....                             | 4068 |
| A.10.5 How many computers do I need to run an NDB Cluster, and why? .....                                                                | 4068 |
| A.10.6 What do the different computers do in an NDB Cluster? .....                                                                       | 4068 |
| A.10.7 When I run the <code>SHOW</code> command in the NDB Cluster management client, I see a line of output that looks like this: ..... | 4069 |
| A.10.8 With which operating systems can I use NDB Cluster? .....                                                                         | 4069 |

|                                                                                                                                                     |      |

| A.10.9 What are the hardware requirements for running NDB Cluster? .....                                                                            | 4069 |
| A.10.10 How much RAM do I need to use NDB Cluster? Is it possible to use disk memory at all? .                                                      | 4069 |
| A.10.11 What file systems can I use with NDB Cluster? What about network file systems or network shares? .....                                      | 4070 |
| A.10.12 Can I run NDB Cluster nodes inside virtual machines (such as those created by VMWare, VirtualBox, Parallels, or Xen)? .....                 | 4071 |
| A.10.13 I am trying to populate an NDB Cluster database. The loading process terminates prematurely and I get an error message like this one: ..... | 4071 |
| A.10.14 NDB Cluster uses TCP/IP. Does this mean that I can run it over the Internet, with one or more nodes in remote locations? .....              | 4071 |
| A.10.15 Do I have to learn a new programming or query language to use NDB Cluster? .....                                                            | 4072 |
| A.10.16 What programming languages and APIs are supported by NDB Cluster? .....                                                                     | 4072 |
| A.10.17 Does NDB Cluster include any management tools? .....                                                                                        | 4072 |
| A.10.18 How do I find out what an error or warning message means when using NDB Cluster? ...                                                        | 4073 |
| A.10.19 Is NDB Cluster transaction-safe? What isolation levels are supported? .....                                                                 | 4073 |
| A.10.20 What storage engines are supported by NDB Cluster? .....                                                                                    | 4073 |
| A.10.21 In the event of a catastrophic failure—for example, the whole city loses power and my UPS fails—would I lose all my data? .....             | 4073 |
| A.10.22 Is it possible to use <code>FULLTEXT</code> indexes with NDB Cluster? .....                                                                 | 4073 |
| A.10.23 Can I run multiple nodes on a single computer? .....                                                                                        | 4073 |
| A.10.24 Can I add data nodes to an NDB Cluster without restarting it? .....                                                                         | 4074 |
| A.10.25 Are there any limitations that I should be aware of when using NDB Cluster? .....                                                           | 4074 |
| A.10.26 Does NDB Cluster support foreign keys? .....                                                                                                | 4074 |
| A.10.27 How do I import an existing MySQL database into an NDB Cluster? .....                                                                       | 4075 |
| A.10.28 How do NDB Cluster nodes communicate with one another? .....                                                                                | 4075 |
| A.10.29 What is an <i>arbitrator</i> ? .....                                                                                                        | 4075 |
| A.10.30 What data types are supported by NDB Cluster? .....                                                                                         | 4075 |
| A.10.31 How do I start and stop NDB Cluster? .....                                                                                                  | 4076 |
| A.10.32 What happens to NDB Cluster data when the NDB Cluster is shut down? .....                                                                   | 4077 |
| A.10.33 Is it a good idea to have more than one management node for an NDB Cluster? .....                                                           | 4077 |
| A.10.34 Can I mix different kinds of hardware and operating systems in one NDB Cluster? .....                                                       | 4077 |
| A.10.35 Can I run two data nodes on a single host? Two SQL nodes? .....                                                                             | 4077 |
| A.10.36 Can I use host names with NDB Cluster? .....                                                                                                | 4077 |
| A.10.37 Does NDB Cluster support IPv6? .....                                                                                                        | 4077 |
| A.10.38 How do I handle MySQL users in an NDB Cluster having multiple MySQL servers? .....                                                          | 4077 |
| A.10.39 How do I continue to send queries in the event that one of the SQL nodes fails? .....                                                       | 4078 |
| A.10.40 How do I back up and restore an NDB Cluster? .....                                                                                          | 4078 |
| A.10.41 What is an “angel process”? .....                                                                                                           | 4078 |

**A.10.1** Which versions of the MySQL software support NDB Cluster? Do I have to compile from source?

NDB Cluster is not supported in standard MySQL Server 5.7 releases. Instead, MySQL NDB Cluster is provided as a separate product. Available NDB Cluster release series include the following:

- **NDB Cluster 7.2.** This series is no longer supported for new deployments or maintained. Users of NDB Cluster 7.2 should upgrade to a newer release series as soon as possible. We recommend that new deployments use the latest NDB Cluster 8.0 release.
- **NDB Cluster 7.3.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production use, although we recommend that new deployments use the latest NDB Cluster 8.0 release. The most recent NDB Cluster 7.3 release can be obtained from <https://dev.mysql.com/downloads/cluster/>.
- **NDB Cluster 7.4.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production use, although we recommend that new deployments use the latest NDB Cluster 8.0 release. The most recent NDB Cluster 7.4 release can be obtained from <https://dev.mysql.com/downloads/cluster/>.

- **NDB Cluster 7.5.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production use, although we recommend that new deployments use the latest NDB Cluster 7.6 release. The latest NDB Cluster 7.5 releases can be obtained from <https://dev.mysql.com/downloads/cluster/>.
- **NDB Cluster 7.6.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production use, although we recommend that new deployments use the latest NDB Cluster 8.0 release. The latest NDB Cluster 7.6 releases can be obtained from <https://dev.mysql.com/downloads/cluster/>.
- **NDB Cluster 8.0.** This series is the most recent General Availability (GA) version of NDB Cluster, based on version 8.0 of the [NDB](#) storage engine and MySQL Server 8.0. NDB Cluster 8.0 is available for production use; new deployments intended for production should use the latest GA release in this series, which is currently NDB Cluster 8.0.26. You can obtain the most recent NDB Cluster 8.0 release from <https://dev.mysql.com/downloads/cluster/>. For information about new features and other important changes in this series, see [What is New in NDB Cluster](#).

You can obtain and compile NDB Cluster from source (see [Section 21.2.1.4, “Building NDB Cluster from Source on Linux”](#), and [Section 21.2.2.2, “Compiling and Installing NDB Cluster from Source on Windows”](#)), but for all but the most specialized cases, we recommend using one of the following installers provided by Oracle that is appropriate to your operating platform and circumstances:

- The web-based [NDB Cluster Auto-Installer](#) (works on all platforms supported by [NDB](#))
- Linux [binary release](#) ([tar.gz](#) file)
- Linux [RPM package](#)
- Linux [.deb file](#)
- Windows [binary “no-install” release](#)
- Windows [MSI Installer](#)

Installation packages may also be available from your platform's package management system.

You can determine whether your MySQL Server has [NDB](#) support using one of the statements `SHOW VARIABLES LIKE 'have_%'`, `SHOW ENGINES`, or `SHOW PLUGINS`.

#### A.10.2 What do “NDB” and “NDBCLUSTER” mean?

“NDB” stands for “**N**etwork **D**atabase”. [NDB](#) and [NDBCLUSTER](#) are both names for the storage engine that enables clustering support with MySQL. [NDB](#) is preferred, but either name is correct.

#### A.10.3 What is the difference between using NDB Cluster versus using MySQL Replication?

In traditional MySQL replication, a source MySQL server updates one or more replicas. Transactions are committed sequentially, and a slow transaction can cause the replica to lag behind the source. This means that if the source fails, it is possible that the replica might not have recorded the last few transactions. If a transaction-safe engine such as [InnoDB](#) is being used, a transaction is either completed on the replica or not applied at all, but replication does not guarantee that all data on the source and the replica remains consistent at all times. In NDB Cluster, all data nodes are kept in synchrony, and a transaction committed by any one data node is committed for all data nodes. In the event of a data node failure, all remaining data nodes remain in a consistent state.

In short, whereas standard MySQL replication is *asynchronous*, NDB Cluster is *synchronous*.

Asynchronous replication is also available in NDB Cluster. *NDB Cluster Replication* (also sometimes known as “geo-replication”) includes the capability to replicate both between two NDB Clusters, and from an NDB Cluster to a non-Cluster MySQL server. See [Section 21.6, “NDB Cluster Replication”](#).

**A.10.4** Do I need any special networking to run NDB Cluster? How do computers in a cluster communicate?

NDB Cluster is intended to be used in a high-bandwidth environment, with computers connecting using TCP/IP. Its performance depends directly upon the connection speed between the cluster's computers. The minimum connectivity requirements for NDB Cluster include a typical 100-megabit Ethernet network or the equivalent. We recommend you use gigabit Ethernet whenever available.

**A.10.5** How many computers do I need to run an NDB Cluster, and why?

A minimum of three computers is required to run a viable cluster. However, the minimum recommended number of computers in an NDB Cluster is four: one each to run the management and SQL nodes, and two computers to serve as data nodes. The purpose of the two data nodes is to provide redundancy; the management node must run on a separate machine to guarantee continued arbitration services in the event that one of the data nodes fails.

To provide increased throughput and high availability, you should use multiple SQL nodes (MySQL Servers connected to the cluster). It is also possible (although not strictly necessary) to run multiple management servers.

**A.10.6** What do the different computers do in an NDB Cluster?

An NDB Cluster has both a physical and logical organization, with computers being the physical elements. The logical or functional elements of a cluster are referred to as *nodes*, and a computer housing a cluster node is sometimes referred to as a *cluster host*. There are three types of nodes, each corresponding to a specific role within the cluster. These are:

- **Management node.** This node provides management services for the cluster as a whole, including startup, shutdown, backups, and configuration data for the other nodes. The management node server is implemented as the application `ndb_mgmd`; the management client used to control NDB Cluster is `ndb_mgm`. See [Section 21.4.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#), and [Section 21.4.5, “ndb\\_mgm — The NDB Cluster Management Client”](#), for information about these programs.
- **Data node.** This type of node stores and replicates data. Data node functionality is handled by instances of the NDB data node process `ndbd`. For more information, see [Section 21.4.1, “ndbd — The NDB Cluster Data Node Daemon”](#).
- **SQL node.** This is simply an instance of MySQL Server (`mysqld`) that is built with support for the `NDBCLUSTER` storage engine and started with the `--ndb-cluster` option to enable the engine and the `--ndb-connectstring` option to enable it to connect to an NDB Cluster management server. For more about these options, see [MySQL Server Options for NDB Cluster](#).

**Note**

An *API node* is any application that makes direct use of Cluster data nodes for data storage and retrieval. An SQL node can thus be considered a type of API node that uses a MySQL Server to provide an SQL interface to the Cluster. You can write such applications (that do not depend on a MySQL Server) using the NDB API, which supplies a direct, object-oriented transaction and scanning interface to NDB Cluster data; see [NDB Cluster API Overview: The NDB API](#), for more information.

**A.10.7** When I run the `SHOW` command in the NDB Cluster management client, I see a line of output that looks like this:

```
id=2 @10.100.10.32 (Version: 8.0.26-ndb-8.0.26 Nodegroup: 0, *)
```

What does the `*` mean? How is this node different from the others?

The simplest answer is, “It’s not something you can control, and it’s nothing that you need to worry about in any case, unless you’re a software engineer writing or analyzing the NDB Cluster source code”.

If you don’t find that answer satisfactory, here’s a longer and more technical version:

A number of mechanisms in NDB Cluster require distributed coordination among the data nodes. These distributed algorithms and protocols include global checkpointing, DDL (schema) changes, and node restart handling. To make this coordination simpler, the data nodes “elect” one of their number to act as leader. There is no user-facing mechanism for influencing this selection, which is completely automatic; the fact that it *is* automatic is a key part of NDB Cluster’s internal architecture.

When a node acts as the “leader” for any of these mechanisms, it is usually the point of coordination for the activity, and the other nodes act as “followers”, carrying out their parts of the activity as directed by the leader. If the node acting as leader fails, then the remaining nodes elect a new leader. Tasks in progress that were being coordinated by the old leader may either fail or be continued by the new leader, depending on the actual mechanism involved.

It is possible for some of these different mechanisms and protocols to have different leader nodes, but in general the same leader is chosen for all of them. The node indicated as the leader in the output of `SHOW` in the management client is known internally as the `DICT` manager, responsible for coordinating DDL and metadata activity.

NDB Cluster is designed in such a way that the choice of leader has no discernible effect outside the cluster itself. For example, the current leader does not have significantly higher CPU or resource usage than the other data nodes, and failure of the leader should not have a significantly different impact on the cluster than the failure of any other data node.

**A.10.8** With which operating systems can I use NDB Cluster?

NDB Cluster is supported on most Unix-like operating systems. NDB Cluster is also supported in production settings on Microsoft Windows operating systems.

For more detailed information concerning the level of support which is offered for NDB Cluster on various operating system versions, operating system distributions, and hardware platforms, please refer to <https://www.mysql.com/support/supportedplatforms/cluster.html>.

**A.10.9** What are the hardware requirements for running NDB Cluster?

NDB Cluster should run on any platform for which `NDB`-enabled binaries are available. For data nodes and API nodes, faster CPUs and more memory are likely to improve performance, and 64-bit CPUs are likely to be more effective than 32-bit processors. There must be sufficient memory on machines used for data nodes to hold each node’s share of the database (see *How much RAM do I Need?* for more information). For a computer which is used only for running the NDB Cluster management server, the requirements are minimal; a common desktop PC (or the equivalent) is generally sufficient for this task. Nodes can communicate through the standard TCP/IP network and hardware. They can also use the high-speed SCI protocol; however, special networking hardware and software are required to use SCI (see [Section 21.3.4, “Using High-Speed Interconnects with NDB Cluster”](#)).

**A.10.10** How much RAM do I need to use NDB Cluster? Is it possible to use disk memory at all?

NDB Cluster was originally implemented as in-memory only, but all versions currently available also provide the ability to store NDB Cluster on disk. See [Section 21.5.10, “NDB Cluster Disk Data Tables”](#), for more information.

For in-memory [NDB](#) tables, you can use the following formula for obtaining a rough estimate of how much RAM is needed for each data node in the cluster:

```
(SizeofDatabase × NumberOfReplicas × 1.1) / NumberOfDataNodes
```

To calculate the memory requirements more exactly requires determining, for each table in the cluster database, the storage space required per row (see [Section 11.7, “Data Type Storage Requirements”](#), for details), and multiplying this by the number of rows. You must also remember to account for any column indexes as follows:

- Each primary key or hash index created for an [NDBCLUSTER](#) table requires 21–25 bytes per record. These indexes use [IndexMemory](#).
- Each ordered index requires 10 bytes storage per record, using [DataMemory](#).
- Creating a primary key or unique index also creates an ordered index, unless this index is created with [USING HASH](#). In other words:
  - A primary key or unique index on a Cluster table normally takes up 31 to 35 bytes per record.
  - However, if the primary key or unique index is created with [USING HASH](#), then it requires only 21 to 25 bytes per record.

Creating NDB Cluster tables with [USING HASH](#) for all primary keys and unique indexes generally causes table updates to run more quickly—in some cases by as much as 20 to 30 percent faster than updates on tables where [USING HASH](#) was not used in creating primary and unique keys. This is due to the fact that less memory is required (because no ordered indexes are created), and that less CPU must be utilized (because fewer indexes must be read and possibly updated). However, it also means that queries that could otherwise use range scans must be satisfied by other means, which can result in slower selects.

When calculating Cluster memory requirements, you may find useful the [ndb\\_size.pl](#) utility which is available in recent MySQL 5.7 releases. This Perl script connects to a current (non-Cluster) MySQL database and creates a report on how much space that database would require if it used the [NDBCLUSTER](#) storage engine. For more information, see [Section 21.4.29, “ndb\\_size.pl — NDBCLUSTER Size Requirement Estimator”](#).

It is especially important to keep in mind that *every NDB Cluster table must have a primary key*. The [NDB](#) storage engine creates a primary key automatically if none is defined; this primary key is created without [USING HASH](#).

You can determine how much memory is being used for storage of NDB Cluster data and indexes at any given time using the [REPORT MEMORYUSAGE](#) command in the [ndb\\_mgm](#) client; see [Section 21.5.1, “Commands in the NDB Cluster Management Client”](#), for more information. In addition, warnings are written to the cluster log when 80% of available [DataMemory](#) or (prior to NDB 7.6) [IndexMemory](#) is in use, and again when usage reaches 90%, 99%, and 100%.

#### A.10.1 What file systems can I use with NDB Cluster? What about network file systems or network shares?

Generally, any file system that is native to the host operating system should work well with NDB Cluster. If you find that a given file system works particularly well (or not so especially well) with NDB Cluster, we invite you to discuss your findings in the [NDB Cluster Forums](#).

For Windows, we recommend that you use [NTFS](#) file systems for NDB Cluster, just as we do for standard MySQL. We do not test NDB Cluster with [FAT](#) or [VFAT](#) file systems. Because of this, we do not recommend their use with MySQL or NDB Cluster.

NDB Cluster is implemented as a shared-nothing solution; the idea behind this is that the failure of a single piece of hardware should not cause the failure of multiple cluster nodes, or possibly even the failure of the cluster as a whole. For this reason, the use of network shares or network file systems is not supported for NDB Cluster. This also applies to shared storage devices such as SANs.

**A.10.12** Can I run NDB Cluster nodes inside virtual machines (such as those created by VMWare, VirtualBox, Parallels, or Xen)?

NDB Cluster is supported for use in virtual machines. We currently support and test using [Oracle VM](#).

Some NDB Cluster users have successfully deployed NDB Cluster using other virtualization products; in such cases, Oracle can provide NDB Cluster support, but issues specific to the virtual environment must be referred to that product's vendor.

**A.10.13** I am trying to populate an NDB Cluster database. The loading process terminates prematurely and I get an error message like this one:

```
ERROR 1114: The table 'my_cluster_table' is full
```

Why is this happening?

The cause is very likely to be that your setup does not provide sufficient RAM for all table data and all indexes, *including the primary key required by the NDB storage engine and automatically created in the event that the table definition does not include the definition of a primary key*.

It is also worth noting that all data nodes should have the same amount of RAM, since no data node in a cluster can use more memory than the least amount available to any individual data node. For example, if there are four computers hosting Cluster data nodes, and three of these have 3GB of RAM available to store Cluster data while the remaining data node has only 1GB RAM, then each data node can devote at most 1GB to NDB Cluster data and indexes.

In some cases it is possible to get `Table is full` errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free `DataMemory`. You can force [NDB](#) to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the `MAX_ROWS` option for `CREATE TABLE`. In general, setting `MAX_ROWS` to twice the number of rows that you expect to store in the table should be sufficient.

For similar reasons, you can also sometimes encounter problems with data node restarts on nodes that are heavily loaded with data. The `MinFreePct` parameter can help with this issue by reserving a portion (5% by default) of `DataMemory` and (prior to NDB 7.6) `IndexMemory` for use in restarts. This reserved memory is not available for storing [NDB](#) tables or data.

**A.10.14** NDB Cluster uses TCP/IP. Does this mean that I can run it over the Internet, with one or more nodes in remote locations?

It is very unlikely that a cluster would perform reliably under such conditions, as NDB Cluster was designed and implemented with the assumption that it would be run under conditions guaranteeing dedicated high-speed connectivity such as that found in a LAN setting using 100 Mbps or gigabit Ethernet—preferably the latter. We neither test nor warrant its performance using anything slower than this.

Also, it is extremely important to keep in mind that communications between the nodes in an NDB Cluster are not secure; they are neither encrypted nor safeguarded by any other protective

mechanism. The most secure configuration for a cluster is in a private network behind a firewall, with no direct access to any Cluster data or management nodes from outside. (For SQL nodes, you should take the same precautions as you would with any other instance of the MySQL server.) For more information, see [Section 21.5.17, “NDB Cluster Security Issues”](#).

**A.10.15** Do I have to learn a new programming or query language to use NDB Cluster?

No. Although some specialized commands are used to manage and configure the cluster itself, only standard (My)SQL statements are required for the following operations:

- Creating, altering, and dropping tables
- Inserting, updating, and deleting table data
- Creating, changing, and dropping primary and unique indexes

Some specialized configuration parameters and files are required to set up an NDB Cluster—see [Section 21.3.3, “NDB Cluster Configuration Files”](#), for information about these.

A few simple commands are used in the NDB Cluster management client (`ndb_mgm`) for tasks such as starting and stopping cluster nodes. See [Section 21.5.1, “Commands in the NDB Cluster Management Client”](#).

**A.10.16** What programming languages and APIs are supported by NDB Cluster?

NDB Cluster supports the same programming APIs and languages as the standard MySQL Server, including ODBC, .Net, the MySQL C API, and numerous drivers for popular scripting languages such as PHP, Perl, and Python. NDB Cluster applications written using these APIs behave similarly to other MySQL applications; they transmit SQL statements to a MySQL Server (in the case of NDB Cluster, an SQL node), and receive responses containing rows of data. For more information about these APIs, see [Chapter 27, Connectors and APIs](#).

NDB Cluster also supports application programming using the NDB API, which provides a low-level C++ interface to NDB Cluster data without needing to go through a MySQL Server. See [The NDB API](#). In addition, many `NDBCLUSTER` management functions are exposed by the C-language MGM API; see [The MGM API](#), for more information.

NDB Cluster also supports Java application programming using ClusterJ, which supports a domain object model of data using sessions and transactions. See [Java and NDB Cluster](#), for more information.

In addition, NDB Cluster provides support for `memcached`, allowing developers to access data stored in NDB Cluster using the `memcached` interface; for more information, see [ndbmemcache — Memcache API for NDB Cluster \(NO LONGER SUPPORTED\)](#).

NDB Cluster also includes adapters supporting NoSQL applications written against `Node.js`, with NDB Cluster as the data store. See [MySQL NoSQL Connector for JavaScript](#), for more information.

**A.10.17** Does NDB Cluster include any management tools?

NDB Cluster includes a command line client for performing basic management functions. See [Section 21.4.5, “ndb\\_mgm — The NDB Cluster Management Client”](#), and [Section 21.5.1, “Commands in the NDB Cluster Management Client”](#).

NDB Cluster 7.6 and earlier are also supported by MySQL Cluster Manager, a separate product providing an advanced command line interface that can automate many NDB Cluster management tasks such as rolling restarts and configuration changes. Beginning with version 1.4.8, MySQL Cluster Manager also provides experimental support for NDB Cluster 8.0. For more information about MySQL Cluster Manager, see [MySQL™ Cluster Manager 1.4.8 User Manual](#).

NDB Cluster also provides a graphical, browser-based Auto-Installer for setting up and deploying NDB Cluster, as part of the NDB Cluster software distribution. For more information, see [Section 21.2.8, “The NDB Cluster Auto-Installer \(NDB 7.5\) \(No longer supported\)”](#).

**A.10.18** How do I find out what an error or warning message means when using NDB Cluster?

There are two ways in which this can be done:

- From within the `mysql` client, use `SHOW ERRORS` or `SHOW WARNINGS` immediately upon being notified of the error or warning condition.
- From a system shell prompt, use `perror --ndb error_code`.

**A.10.19** Is NDB Cluster transaction-safe? What isolation levels are supported?

Yes. For tables created with the `NDB` storage engine, transactions are supported. Currently, NDB Cluster supports only the `READ COMMITTED` transaction isolation level.

**A.10.20** What storage engines are supported by NDB Cluster?

NDB Cluster requires the `NDB` storage engine. That is, in order for a table to be shared between nodes in an NDB Cluster, the table must be created using `ENGINE=NDB` (or the equivalent option `ENGINE=NDCLUSTER`).

It is possible to create tables using other storage engines (such as `InnoDB` or `MyISAM`) on a MySQL server being used with NDB Cluster, but since these tables do not use `NDB`, they do not participate in clustering; each such table is strictly local to the individual MySQL server instance on which it is created.

NDB Cluster is quite different from `InnoDB` clustering with regard to architecture, requirements, and implementation; despite any similarity in their names, the two are not compatible. For more information about `InnoDB` clustering, see [Using MySQL AdminAPI](#). See also [Section 21.1.6, “MySQL Server Using InnoDB Compared with NDB Cluster”](#), for information about the differences between the `NDB` and `InnoDB` storage engines.

**A.10.21** In the event of a catastrophic failure—for example, the whole city loses power *and* my UPS fails—would I lose all my data?

All committed transactions are logged. Therefore, although it is possible that some data could be lost in the event of a catastrophe, this should be quite limited. Data loss can be further reduced by minimizing the number of operations per transaction. (It is not a good idea to perform large numbers of operations per transaction in any case.)

**A.10.22** Is it possible to use `FULLTEXT` indexes with NDB Cluster?

`FULLTEXT` indexing is currently supported only by the `InnoDB` and `MyISAM` storage engines. See [Section 12.10, “Full-Text Search Functions”](#), for more information.

**A.10.23** Can I run multiple nodes on a single computer?

It is possible but not always advisable. One of the chief reasons to run a cluster is to provide redundancy. To obtain the full benefits of this redundancy, each node should reside on a separate machine. If you place multiple nodes on a single machine and that machine fails, you lose all of those nodes. For this reason, if you do run multiple data nodes on a single machine, it is *extremely* important that they be set up in such a way that the failure of this machine does not cause the loss of all the data nodes in a given node group.

Given that NDB Cluster can be run on commodity hardware loaded with a low-cost (or even no-cost) operating system, the expense of an extra machine or two is well worth it to safeguard mission-critical data. It also worth noting that the requirements for a cluster host running a management node are minimal. This task can be accomplished with a 300 MHz Pentium or

equivalent CPU and sufficient RAM for the operating system, plus a small amount of overhead for the `ndb_mgmd` and `ndb_mgm` processes.

It is acceptable to run multiple cluster data nodes on a single host that has multiple CPUs, cores, or both. The NDB Cluster distribution also provides a multithreaded version of the data node binary intended for use on such systems. For more information, see [Section 21.4.3, “ndbmtd — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”.](#)

It is also possible in some cases to run data nodes and SQL nodes concurrently on the same machine; how well such an arrangement performs is dependent on a number of factors such as number of cores and CPUs as well as the amount of disk and memory available to the data node and SQL node processes, and you must take these factors into account when planning such a configuration.

#### A.10.20 Can I add data nodes to an NDB Cluster without restarting it?

It is possible to add new data nodes to a running NDB Cluster without taking the cluster offline. For more information, see [Section 21.5.7, “Adding NDB Cluster Data Nodes Online”](#).

For other types of NDB Cluster nodes, a rolling restart is all that is required (see [Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)).

#### A.10.21 Are there any limitations that I should be aware of when using NDB Cluster?

Limitations on `NDB` tables in MySQL NDB Cluster include the following:

- Temporary tables are not supported; a `CREATE TEMPORARY TABLE` statement using `ENGINE=NDB` or `ENGINE=NDCLUSTER` fails with an error.
- The only types of user-defined partitioning supported for `NDCLUSTER` tables are `KEY` and `LINEAR KEY`. Trying to create an `NDB` table using any other partitioning type fails with an error.
- `FULLTEXT` indexes are not supported.
- Index prefixes are not supported. Only complete columns may be indexed.
- Spatial indexes are not supported (although spatial columns can be used). See [Section 11.4, “Spatial Data Types”](#).
- Support for partial transactions and partial rollbacks is comparable to that of other transactional storage engines such as `InnoDB` that can roll back individual statements.
- The maximum number of attributes allowed per table is 512. Attribute names cannot be any longer than 31 characters. For each table, the maximum combined length of the table and database names is 122 characters.
- Prior to NDB 8.0, the maximum size for a table row is 14 kilobytes, not counting `BLOB` values. In NDB 8.0, this maximum is increased to 30000 bytes. See [Section 21.1.7.5, “Limits Associated with Database Objects in NDB Cluster”](#), for more information.

There is no set limit for the number of rows per `NDB` table. Limits on table size depend on a number of factors, in particular on the amount of RAM available to each data node.

For a complete listing of limitations in NDB Cluster, see [Section 21.1.7, “Known Limitations of NDB Cluster”](#). See also [Previous NDB Cluster Issues Resolved in NDB Cluster 8.0](#).

#### A.10.22 Does NDB Cluster support foreign keys?

NDB Cluster provides support for foreign key constraints which is comparable to that found in the `InnoDB` storage engine; see [Section 1.7.3.2, “FOREIGN KEY Constraints”](#), for more

detailed information, as well as [Section 13.1.18.5, “FOREIGN KEY Constraints”](#). Applications requiring foreign key support should use NDB Cluster 7.3, 7.4, 7.5, or later.

#### A.10.27 How do I import an existing MySQL database into an NDB Cluster?

You can import databases into NDB Cluster much as you would with any other version of MySQL. Other than the limitations mentioned elsewhere in this FAQ, the only other special requirement is that any tables to be included in the cluster must use the `NDB` storage engine. This means that the tables must be created with `ENGINE=NDB` or `ENGINE=NDCLUSTER`.

It is also possible to convert existing tables that use other storage engines to `NDCLUSTER` using one or more `ALTER TABLE` statement. However, the definition of the table must be compatible with the `NDCLUSTER` storage engine prior to making the conversion. In MySQL 5.7, an additional workaround is also required; see [Section 21.1.7, “Known Limitations of NDB Cluster”](#), for details.

#### A.10.28 How do NDB Cluster nodes communicate with one another?

Cluster nodes can communicate through any of three different transport mechanisms: TCP/IP, SHM (shared memory), and SCI (Scalable Coherent Interface). Where available, SHM is used by default between nodes residing on the same cluster host; however, this is considered experimental. SCI is a high-speed (1 gigabit per second and higher), high-availability protocol used in building scalable multi-processor systems; it requires special hardware and drivers. See [Section 21.3.4, “Using High-Speed Interconnects with NDB Cluster”](#), for more about using SCI as a transport mechanism for NDB Cluster.

#### A.10.29 What is an *arbitrator*?

If one or more data nodes in a cluster fail, it is possible that not all cluster data nodes are able to “see” one another. In fact, it is possible that two sets of data nodes might become isolated from one another in a network partitioning, also known as a “split-brain” scenario. This type of situation is undesirable because each set of data nodes tries to behave as though it is the entire cluster. An arbitrator is required to decide between the competing sets of data nodes.

When all data nodes in at least one node group are alive, network partitioning is not an issue, because no single subset of the cluster can form a functional cluster on its own. The real problem arises when no single node group has all its nodes alive, in which case network partitioning (the “split-brain” scenario) becomes possible. Then an arbitrator is required. All cluster nodes recognize the same node as the arbitrator, which is normally the management server; however, it is possible to configure any of the MySQL Servers in the cluster to act as the arbitrator instead. The arbitrator accepts the first set of cluster nodes to contact it, and tells the remaining set to shut down. Arbitrator selection is controlled by the `ArbitrationRank` configuration parameter for MySQL Server and management server nodes. You can also use the `ArbitrationRank` configuration parameter to control the arbitrator selection process. For more information about these parameters, see [Section 21.3.3.5, “Defining an NDB Cluster Management Server”](#).

The role of arbitrator does not in and of itself impose any heavy demands upon the host so designated, and thus the arbitrator host does not need to be particularly fast or to have extra memory especially for this purpose.

#### A.10.30 What data types are supported by NDB Cluster?

NDB Cluster supports all of the usual MySQL data types, including those associated with MySQL's spatial extensions; however, the `NDB` storage engine does not support spatial indexes. (Spatial indexes are supported only by `MyISAM`; see [Section 11.4, “Spatial Data Types”](#), for more information.) In addition, there are some differences with regard to indexes when used with `NDB` tables.

**Note**

NDB Cluster Disk Data tables (that is, tables created with `TABLESPACE ... STORAGE DISK ENGINE=NDB` or `TABLESPACE ... STORAGE DISK ENGINE=NDCLUSTER`) have only fixed-width rows. This means that (for example) each Disk Data table record containing a `VARCHAR(255)` column requires space for 255 characters (as required for the character set and collation being used for the table), regardless of the actual number of characters stored therein.

See [Section 21.1.7, “Known Limitations of NDB Cluster”](#), for more information about these issues.

### A.10.3 How do I start and stop NDB Cluster?

It is necessary to start each node in the cluster separately, in the following order:

1. Start the management node, using the `ndb_mgmd` command.

You must include the `-f` or `--config-file` option to tell the management node where its configuration file can be found.

2. Start each data node with the `ndbd` command.

Each data node must be started with the `-c` or `--ndb-connectstring` option so that the data node knows how to connect to the management server.

3. Start each MySQL Server (SQL node) using your preferred startup script, such as `mysqld_safe`.

Each MySQL Server must be started with the `--ndbcluster` and `--ndb-connectstring` options. These options cause `mysqld` to enable `NDCLUSTER` storage engine support and how to connect to the management server.

Each of these commands must be run from a system shell on the machine housing the affected node. (You do not have to be physically present at the machine—a remote login shell can be used for this purpose.) You can verify that the cluster is running by starting the `NDB` management client `ndb_mgm` on the machine housing the management node and issuing the `SHOW` or `ALL STATUS` command.

To shut down a running cluster, issue the command `SHUTDOWN` in the management client. Alternatively, you may enter the following command in a system shell:

```
shell> ndb_mgm -e "SHUTDOWN"
```

(The quotation marks in this example are optional, since there are no spaces in the command string following the `-e` option; in addition, the `SHUTDOWN` command, like other management client commands, is not case-sensitive.)

Either of these commands causes the `ndb_mgm`, `ndb_mgm`, and any `ndbd` processes to terminate gracefully. MySQL servers running as SQL nodes can be stopped using `mysqladmin shutdown`.

For more information, see [Section 21.5.1, “Commands in the NDB Cluster Management Client”](#), and [Section 21.2.6, “Safe Shutdown and Restart of NDB Cluster”](#).

MySQL Cluster Manager and the NDB Cluster Auto-Installer provide additional ways to handle starting and stopping of NDB Cluster nodes. See [MySQL™ Cluster Manager 1.4.8 User Manual](#), and [Section 21.2.9, “The NDB Cluster Auto-Installer \(NDB 7.6\) \(No longer supported\)”](#), for more information about these tools.

**A.10.32** What happens to NDB Cluster data when the NDB Cluster is shut down?

The data that was held in memory by the cluster's data nodes is written to disk, and is reloaded into memory the next time that the cluster is started.

**A.10.33** Is it a good idea to have more than one management node for an NDB Cluster?

It can be helpful as a fail-safe. Only one management node controls the cluster at any given time, but it is possible to configure one management node as primary, and one or more additional management nodes to take over in the event that the primary management node fails.

See [Section 21.3.3, “NDB Cluster Configuration Files”](#), for information on how to configure NDB Cluster management nodes.

**A.10.34** Can I mix different kinds of hardware and operating systems in one NDB Cluster?

Yes, as long as all machines and operating systems have the same “endianness” (all big-endian or all little-endian).

It is also possible to use software from different NDB Cluster releases on different nodes. However, we support such use only as part of a rolling upgrade procedure (see [Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)).

**A.10.35** Can I run two data nodes on a single host? Two SQL nodes?

Yes, it is possible to do this. In the case of multiple data nodes, it is advisable (but not required) for each node to use a different data directory. If you want to run multiple SQL nodes on one machine, each instance of `mysqld` must use a different TCP/IP port.

Running data nodes and SQL nodes together on the same host is possible, but you should be aware that the `ndbd` or `ndbmt` processes may compete for memory with `mysqld`.

**A.10.36** Can I use host names with NDB Cluster?

Yes, it is possible to use DNS and DHCP for cluster hosts. However, if your application requires “five nines” availability, you should use fixed (numeric) IP addresses, since making communication between Cluster hosts dependent on services such as DNS and DHCP introduces additional potential points of failure.

**A.10.37** Does NDB Cluster support IPv6?

IPv6 is supported for connections between SQL nodes (MySQL servers), but connections between all other types of NDB Cluster nodes must use IPv4.

In practical terms, this means that you can use IPv6 for replication between NDB Clusters, but connections between nodes in the same NDB Cluster must use IPv4. For more information, see [Section 21.6.3, “Known Issues in NDB Cluster Replication”](#).

**A.10.38** How do I handle MySQL users in an NDB Cluster having multiple MySQL servers?

MySQL user accounts and privileges are normally not automatically propagated between different MySQL servers accessing the same NDB Cluster. MySQL NDB Cluster provides support for distributed privileges, which you can enable by following a procedure provided in the documentation; see [Section 21.5.12, “Distributed Privileges Using Shared Grant Tables”](#), for more information.

**Important**

The mechanism for handling users distributed or shared between NDB Cluster SQL nodes has changed significantly in NDB 8.0; this implementation is not compatible with that in NDB 7.6 and earlier. See [Distributed MySQL Privileges with NDB\\_STORED\\_USER](#), for details.

**A.10.39** How do I continue to send queries in the event that one of the SQL nodes fails?

MySQL NDB Cluster does not provide any sort of automatic failover between SQL nodes. Your application must be prepared to handle the loss of SQL nodes and to fail over between them.

**A.10.40** How do I back up and restore an NDB Cluster?

You can use the NDB Cluster native backup and restore functionality in the NDB management client and the `ndb_restore` program. See [Section 21.5.8, “Online Backup of NDB Cluster”](#), and [Section 21.4.24, “ndb\\_restore — Restore an NDB Cluster Backup”](#).

You can also use the traditional functionality provided for this purpose in `mysqldump` and the MySQL server. See [Section 4.5.4, “mysqldump — A Database Backup Program”](#), for more information.

**A.10.41** What is an “angel process”?

This process monitors and, if necessary, attempts to restart the data node process. If you check the list of active processes on your system after starting `ndbd`, you can see that there are actually 2 processes running by that name, as shown here (we omit the output from `ndb_mgmd` and `ndbd` for brevity):

```
shell> ./ndb_mgmd
shell> ps aux | grep ndb
me 23002 0.0 0.0 122948 3104 ? Ssl 14:14 0:00 ./ndb_mgmd
me 23025 0.0 0.0 5284 820 pts/2 S+ 14:14 0:00 grep ndb

shell> ./ndbd -c 127.0.0.1 --initial
shell> ps aux | grep ndb
me 23002 0.0 0.0 123080 3356 ? Ssl 14:14 0:00 ./ndb_mgmd
me 23096 0.0 0.0 35876 2036 ? Ss 14:14 0:00 ./ndbmtd -c 127.0.0.1 --initial
me 23097 1.0 2.4 524116 91096 ? S1 14:14 0:00 ./ndbmtd -c 127.0.0.1 --initial
me 23168 0.0 0.0 5284 812 pts/2 R+ 14:15 0:00 grep ndb
```

The `ndbd` process showing `0.0` for both memory and CPU usage is the angel process (although it actually does use a very small amount of each). This process merely checks to see if the main `ndbd` or `ndbmtd` process (the primary data node process which actually handles the data) is running. If permitted to do so (for example, if the `StopOnError` configuration parameter is set to `false`), the angel process tries to restart the primary data node process.

## A.11 MySQL 5.7 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

This set of Frequently Asked Questions derives from the experience of MySQL's Support and Development groups in handling many inquiries about CJK (Chinese-Japanese-Korean) issues.

|                                                                                                                                           |      |
|-------------------------------------------------------------------------------------------------------------------------------------------|------|
| A.11.1 What CJK character sets are available in MySQL? .....                                                                              | 4079 |
| A.11.2 I have inserted CJK characters into my table. Why does <code>SELECT</code> display them as “?” characters? .....                   | 4080 |
| A.11.3 What problems should I be aware of when working with the Big5 Chinese character set? ..                                            | 4082 |
| A.11.4 Why do Japanese character set conversions fail? .....                                                                              | 4082 |
| A.11.5 What should I do if I want to convert SJIS 81CA to cp932? .....                                                                    | 4083 |
| A.11.6 How does MySQL represent the Yen (¥) sign? .....                                                                                   | 4083 |
| A.11.7 Of what issues should I be aware when working with Korean character sets in MySQL? ....                                            | 4083 |

### A.11.1 What CJK character sets are available in MySQL?

The list of CJK character sets may vary depending on your MySQL version. For example, the `gb18030` character set is not supported prior to MySQL 5.7.4. However, since the name of the applicable language appears in the `DESCRIPTION` column for every entry in the `INFORMATION_SCHEMA.CHARACTER_SETS` table, you can obtain a current list of all the non-Unicode CJK character sets using this query:

```
mysql> SELECT CHARACTER_SET_NAME, DESCRIPTION
 FROM INFORMATION_SCHEMA.CHARACTER_SETS
 WHERE DESCRIPTION LIKE '%Chin%'
 OR DESCRIPTION LIKE '%Japanese%'
 OR DESCRIPTION LIKE '%Korean%'
 ORDER BY CHARACTER_SET_NAME;
+-----+-----+
| CHARACTER_SET_NAME | DESCRIPTION |
+-----+-----+
| big5 | Big5 Traditional Chinese
| cp932 | SJIS for Windows Japanese
| eucjpmst | UJIS for Windows Japanese
| euckr | EUC-KR Korean
| gb18030 | China National Standard GB18030
| gb2312 | GB2312 Simplified Chinese
| gbk | GBK Simplified Chinese
| sjis | Shift-JIS Japanese
| ujis | EUC-JP Japanese
+-----+-----+
```

(For more information, see [Section 24.3.2, “The INFORMATION\\_SCHEMA.CHARACTER\\_SETS Table”](#).)

MySQL supports three variants of the *GB* (*Guojia Biaozhun*, or *National Standard*, or *Simplified Chinese*) character sets which are official in the People's Republic of China: `gb2312`, `gbk`, and (as of MySQL 5.7.4) `gb18030`.

Sometimes people try to insert `gbk` characters into `gb2312`, and it works most of the time because `gbk` is a superset of `gb2312`. But eventually they try to insert a rarer Chinese character and it does not work. (For an example, see Bug #16072).

Here, we try to clarify exactly what characters are legitimate in `gb2312` or `gbk`, with reference to the official documents. Please check these references before reporting `gb2312` or `gbk` bugs:

- The MySQL `gbk` character set is in reality “Microsoft code page 936”. This differs from the official `gbk` for characters `A1A4` (middle dot), `A1AA` (em dash), `A6E0-A6F5`, and `A8BB-A8C0`.
- For a listing of `gbk`/Unicode mappings, see <http://www.unicode.org/Public/MAPPINGS/VENDORS/MICSFT/WINDOWS/CP936.TXT>.

It is also possible to store CJK characters in Unicode character sets, although the available collations may not sort characters quite as you expect:

- The `utf8` and `ucs2` character sets support the characters from Unicode Basic Multilingual Plane (BMP). These characters have code point values between `U+0000` and `U+FFFF`.

- The `utf8mb4`, `utf16`, `utf16le`, and `utf32` character sets support BMP characters, as well as supplementary characters that lie outside the BMP. Supplementary characters have code point values between `U+10000` and `U+10FFFF`.

The collation used for a Unicode character set determines the ability to sort (that is, distinguish) characters in the set:

- Collations based on Unicode Collation Algorithm (UCA) 4.0.0 distinguish only BMP characters.
- Collations based on UCA 5.2.0 or 9.0.0 distinguish BMP and supplementary characters.
- Non-UCA collations may not distinguish all Unicode characters. For example, the `utf8mb4` default collation is `utf8mb4_general_ci`, which distinguishes only BMP characters.

Moreover, distinguishing characters is not the same as ordering them per the conventions of a given CJK language. Currently, MySQL has only one CJK-specific UCA collation, `gb18030_unicode_520_ci` (which requires use of the non-Unicode `gb18030` character set).

For information about Unicode collations and their differentiating properties, including collation properties for supplementary characters, see [Section 10.10.1, “Unicode Character Sets”](#).

#### A.11.2 I have inserted CJK characters into my table. Why does `SELECT` display them as “?” characters?

This problem is usually due to a setting in MySQL that does not match the settings for the application program or the operating system. Here are some common steps for correcting these types of issues:

- *Be certain of what MySQL version you are using.*

Use the statement `SELECT VERSION()`; to determine this.

- *Make sure that the database is actually using the desired character set.*

People often think that the client character set is always the same as either the server character set or the character set used for display purposes. However, both of these are false assumptions. You can make sure by checking the result of `SHOW CREATE TABLE tablename` or, better yet, by using this statement:

```
SELECT character_set_name, collation_name
 FROM information_schema.columns
 WHERE table_schema = your_database_name
 AND table_name = your_table_name
 AND column_name = your_column_name;
```

- *Determine the hexadecimal value of the character or characters that are not being displayed correctly.*

You can obtain this information for a column `column_name` in the table `table_name` using the following query:

```
SELECT HEX(column_name)
 FROM table_name;
```

`3F` is the encoding for the `?` character; this means that `?` is the character actually stored in the column. This most often happens because of a problem converting a particular character from your client character set to the target character set.

- Make sure that a round trip is possible. When you select `literal` (or `_introducer_hexadecimal-value`), do you obtain `literal` as a result?

For example, the Japanese Katakana character *Pe* (𠂇) exists in all CJK character sets, and has the code point value (hexadecimal coding) `0x30da`. To test a round trip for this character, use this query:

```
SELECT '𠂇' AS `𠂇`; /* or SELECT _ucs2 0x30da; */
```

If the result is not also `𠂇`, the round trip failed.

For bug reports regarding such failures, we might ask you to follow up with `SELECT HEX('𠂇');`. Then we can determine whether the client encoding is correct.

- Make sure that the problem is not with the browser or other application, rather than with MySQL.

Use the `mysql` client program to accomplish this task. If `mysql` displays characters correctly but your application does not, your problem is probably due to system settings.

To determine your settings, use the `SHOW VARIABLES` statement, whose output should resemble what is shown here:

```
mysql> SHOW VARIABLES LIKE 'char%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_client | utf8 |
| character_set_connection | utf8 |
| character_set_database | latin1 |
| character_set_filesystem | binary |
| character_set_results | utf8 |
| character_set_server | latin1 |
| character_set_system | utf8 |
| character_sets_dir | /usr/local/mysql/share/mysql/charsets/ |
+-----+-----+
```

These are typical character-set settings for an international-oriented client (notice the use of `utf8` Unicode) connected to a server in the West (`latin1` is a West Europe character set).

Although Unicode (usually the `utf8` variant on Unix, and the `ucs2` variant on Windows) is preferable to Latin, it is often not what your operating system utilities support best. Many Windows users find that a Microsoft character set, such as `cp932` for Japanese Windows, is suitable.

If you cannot control the server settings, and you have no idea what setting your underlying computer uses, try changing to a common character set for the country that you're in (`euckr` = Korea; `gb18030`, `gb2312` or `gbk` = People's Republic of China; `big5` = Taiwan; `sjis`, `ujis`, `cp932`, or `eucjpm` = Japan; `ucs2` or `utf8` = anywhere). Usually it is necessary to change only the client and connection and results settings. The `SET NAMES` statement changes all three at once. For example:

```
SET NAMES 'big5';
```

Once the setting is correct, you can make it permanent by editing `my.cnf` or `my.ini`. For example you might add lines looking like these:

```
[mysqld]
character-set-server=big5
[client]
```

```
default-character-set=big5
```

It is also possible that there are issues with the API configuration setting being used in your application; see *Why does my GUI front end or browser not display CJK characters correctly...?* for more information.

#### A.11.3 What problems should I be aware of when working with the Big5 Chinese character set?

MySQL supports the Big5 character set which is common in Hong Kong and Taiwan (Republic of China). The MySQL [big5](#) character set is in reality Microsoft code page 950, which is very similar to the original [big5](#) character set.

A feature request for adding [HKSCS](#) extensions has been filed. People who need this extension may find the suggested patch for Bug #13577 to be of interest.

#### A.11.4 Why do Japanese character set conversions fail?

MySQL supports the [sjis](#), [ujis](#), [cp932](#), and [eucjpms](#) character sets, as well as Unicode. A common need is to convert between character sets. For example, there might be a Unix server (typically with [sjis](#) or [ujis](#)) and a Windows client (typically with [cp932](#)).

In the following conversion table, the [ucs2](#) column represents the source, and the [sjis](#), [cp932](#), [ujis](#), and [eucjpms](#) columns represent the destinations; that is, the last 4 columns provide the hexadecimal result when we use [CONVERT\(ucs2\)](#) or we assign a [ucs2](#) column containing the value to an [sjis](#), [cp932](#), [ujis](#), or [eucjpms](#) column.

| Character Name            | ucs2 | sjis | cp932 | ujis   | eucjpms |
|---------------------------|------|------|-------|--------|---------|
| BROKEN BAR                | 00A6 | 3F   | 3F    | 8FA2C3 | 3F      |
| FULLWIDTH BROKEN BAR      | FFE4 | 3F   | FA55  | 3F     | 8FA2    |
| YEN SIGN                  | 00A5 | 3F   | 3F    | 20     | 3F      |
| FULLWIDTH YEN SIGN        | FFE5 | 818F | 818F  | A1EF   | 3F      |
| TILDE                     | 007E | 7E   | 7E    | 7E     | 7E      |
| OVERLINE                  | 203E | 3F   | 3F    | 20     | 3F      |
| HORIZONTAL BAR            | 2015 | 815C | 815C  | A1BD   | A1BD    |
| EM DASH                   | 2014 | 3F   | 3F    | 3F     | 3F      |
| REVERSE SOLIDUS           | 005C | 815F | 5C    | 5C     | 5C      |
| FULLWIDTH REVERSE SOLIDUS | FF3C | 3F   | 815F  | 3F     | A1C0    |
| WAVE DASH                 | 301C | 8160 | 3F    | A1C1   | 3F      |
| FULLWIDTH TILDE           | FF5E | 3F   | 8160  | 3F     | A1C1    |
| DOUBLE VERTICAL LINE      | 2016 | 8161 | 3F    | A1C2   | 3F      |
| PARALLEL TO               | 2225 | 3F   | 8161  | 3F     | A1C2    |
| MINUS SIGN                | 2212 | 817C | 3F    | A1DD   | 3F      |
| FULLWIDTH HYPHEN-MINUS    | FF0D | 3F   | 817C  | 3F     | A1DD    |
| CENT SIGN                 | 00A2 | 8191 | 3F    | A1F1   | 3F      |
| FULLWIDTH CENT SIGN       | FFE0 | 3F   | 8191  | 3F     | A1F1    |
| POUND SIGN                | 00A3 | 8192 | 3F    | A1F2   | 3F      |
| FULLWIDTH POUND SIGN      | FFE1 | 3F   | 8192  | 3F     | A1F2    |
| NOT SIGN                  | 00AC | 81CA | 3F    | A2CC   | 3F      |
| FULLWIDTH NOT SIGN        | FFE2 | 3F   | 81CA  | 3F     | A2CC    |

Now consider the following portion of the table.

|                    | <b>ucs2</b> | <b>sjis</b> | <b>cp932</b> |
|--------------------|-------------|-------------|--------------|
| NOT SIGN           | 00AC        | 81CA        | 3F           |
| FULLWIDTH NOT SIGN | FFE2        | 3F          | 81CA         |

This means that MySQL converts the `NOT SIGN` (Unicode `U+00AC`) to `sjis` code point `0x81CA` and to `cp932` code point `3F`. (`3F` is the question mark (“?”). This is what is always used when the conversion cannot be performed.)

#### A.11.5 What should I do if I want to convert SJIS `81CA` to `cp932`?

Our answer is: “?”. There are disadvantages to this, and many people would prefer a “loose” conversion, so that `81CA` (`NOT SIGN`) in `sjis` becomes `81CA` (`FULLWIDTH NOT SIGN`) in `cp932`.

#### A.11.6 How does MySQL represent the Yen (¥) sign?

A problem arises because some versions of Japanese character sets (both `sjis` and `euc`) treat `5C` as a *reverse solidus* (\, also known as a backslash), whereas others treat it as a yen sign (¥).

MySQL follows only one version of the JIS (Japanese Industrial Standards) standard description. In MySQL, `5C` is always the *reverse solidus* (\).

#### A.11.7 Of what issues should I be aware when working with Korean character sets in MySQL?

In theory, while there have been several versions of the `euckr` (*Extended Unix Code Korea*) character set, only one problem has been noted. We use the “ASCII” variant of EUC-KR, in which the code point `0x5c` is REVERSE SOLIDUS, that is \, instead of the “KS-Roman” variant of EUC-KR, in which the code point `0x5c` is WON SIGN (₩). This means that you cannot convert Unicode `U+20A9` to `euckr`:

```
mysql> SELECT
 CONVERT('₩' USING euckr) AS euckr,
 HEX(CONVERT('₩' USING euckr)) AS hexeuckr;
+-----+-----+
| euckr | hexeuckr |
+-----+-----+
| ? | 3F |
+-----+-----+
```

#### A.11.8 Why do I get `Incorrect string value` error messages?

To see the problem, create a table with one Unicode (`ucs2`) column and one Chinese (`gb2312`) column.

```
mysql> CREATE TABLE ch
 (ucs2 CHAR(3) CHARACTER SET ucs2,
 gb2312 CHAR(3) CHARACTER SET gb2312);
```

In nonstrict SQL mode, try to place the rare character ¶ in both columns.

```
mysql> SET sql_mode = '';
mysql> INSERT INTO ch VALUES ('A¶B', 'A¶B');
Query OK, 1 row affected, 1 warning (0.00 sec)
```

The `INSERT` produces a warning. Use the following statement to see what it is:

```
mysql> SHOW WARNINGS\G
***** 1. row *****
 Level: Warning
 Code: 1366
Message: Incorrect string value: '\xE6\xB1\x8CB' for column 'gb2312' at row 1
```

So it is a warning about the `gb2312` column only.

```
mysql> SELECT ucs2,HEX(ucs2),gb2312,HEX(gb2312) FROM ch;
+-----+-----+-----+
| ucs2 | HEX(ucs2) | gb2312 | HEX(gb2312) |
+-----+-----+-----+
| A?B | 00416C4C0042 | A?B | 413F42 |
+-----+-----+-----+
```

Several things need explanation here:

1. The `Ã?B` character is not in the `gb2312` character set, as described earlier.
2. If you are using an old version of MySQL, you may see a different message.
3. A warning occurs rather than an error because MySQL is not set to use strict SQL mode. In nonstrict mode, MySQL tries to do what it can, to get the best fit, rather than give up. With strict SQL mode, the `Incorrect string value` message occurs as an error rather than a warning, and the `INSERT` fails.

#### A.11.9 Why does my GUI front end or browser display CJK characters incorrectly in my application using Access, PHP, or another API?

Obtain a direct connection to the server using the `mysql` client, and try the same query there. If `mysql` responds correctly, the trouble may be that your application interface requires initialization. Use `mysql` to tell you what character set or sets it uses with the statement `SHOW VARIABLES LIKE 'char%';`. If you are using Access, you are most likely connecting with Connector/ODBC. In this case, you should check [Configuring Connector/ODBC](#). If, for example, you use `big5`, you would enter `SET NAMES 'big5'`. (In this case, no `;` character is required.) If you are using ASP, you might need to add `SET NAMES` in the code. Here is an example that has worked in the past:

```
<%
Session.CodePage=0
Dim strConnection
Dim Conn
strConnection="driver={MySQL ODBC 3.51 Driver};server=server;uid=username;" \
 & "pwd=password;database=database;stmt=SET NAMES 'big5';"
Set Conn = Server.CreateObject("ADODB.Connection")
Conn.Open strConnection
%>
```

In much the same way, if you are using any character set other than `latin1` with Connector/NET, you must specify the character set in the connection string. See [Connector/NET Connections](#) for more information.

If you are using PHP, try this:

```
<?php
$link = new mysqli($host, $usr, $pwd, $db);

if(mysqli_connect_errno())
{
 printf("Connect failed: %s\n", mysqli_connect_error());
 exit();
}

$link->query("SET NAMES 'utf8'");
?>
```

In this case, we used `SET NAMES` to change `character_set_client`, `character_set_connection`, and `character_set_results`.

Another issue often encountered in PHP applications has to do with assumptions made by the browser. Sometimes adding or changing a `<meta>` tag suffices to correct the problem: for example, to insure that the user agent interprets page content as `UTF-8`, include `<meta http-equiv="Content-Type" content="text/html; charset=utf-8">` in the `<head>` section of the HTML page.

If you are using Connector/J, see [Using Character Sets and Unicode](#).

#### A.11.10 I've upgraded to MySQL 5.7. How can I revert to behavior like that in MySQL 4.0 with regard to character sets?

In MySQL Version 4.0, there was a single “global” character set for both server and client, and the decision as to which character to use was made by the server administrator. This changed starting with MySQL Version 4.1. What happens now is a “handshake”, as described in [Section 10.4, “Connection Character Sets and Collations”](#):

When a client connects, it sends to the server the name of the character set that it wants to use. The server uses the name to set the `character_set_client`, `character_set_results`, and `character_set_connection` system variables. In effect, the server performs a `SET NAMES` operation using the character set name.

The effect of this is that you cannot control the client character set by starting `mysqld` with `--character-set-server=utf8`. However, some Asian customers prefer the MySQL 4.0 behavior. To make it possible to retain this behavior, we added a `mysqld` switch, `--character-set-client-handshake`, which can be turned off with `--skip-character-set-client-handshake`. If you start `mysqld` with `--skip-character-set-client-handshake`, then, when a client connects, it sends to the server the name of the character set that it wants to use. However, *the server ignores this request from the client*.

By way of example, suppose that your favorite server character set is `latin1`. Suppose further that the client uses `utf8` because this is what the client's operating system supports. Start the server with `latin1` as its default character set:

```
mysqld --character-set-server=latin1
```

And then start the client with the default character set `utf8`:

```
mysql --default-character-set=utf8
```

The resulting settings can be seen by viewing the output of `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'char%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_client | utf8 |
| character_set_connection | utf8 |
| character_set_database | latin1 |
| character_set_filesystem | binary |
| character_set_results | utf8 |
| character_set_server | latin1 |
| character_set_system | utf8 |
| character_sets_dir | /usr/local/mysql/share/mysql/charsets/ |
+-----+-----+
```

Now stop the client, and stop the server using `mysqladmin`. Then start the server again, but this time tell it to skip the handshake like so:

```
mysqld --character-set-server=utf8 --skip-character-set-client-handshake
```

Start the client with `utf8` once again as the default character set, then display the resulting settings:

```
mysql> SHOW VARIABLES LIKE 'char%';
+-----+-----+
| Variable_name | Value
+-----+-----+
| character_set_client | latin1
| character_set_connection | latin1
| character_set_database | latin1
| character_set_filesystem | binary
| character_set_results | latin1
| character_set_server | latin1
| character_set_system | utf8
| character_sets_dir | /usr/local/mysql/share/mysql/charsets/
+-----+-----+
```

As you can see by comparing the differing results from `SHOW VARIABLES`, the server ignores the client's initial settings if the `--skip-character-set-client-handshake` option is used.

#### A.11.1 Why do some `LIKE` and `FULLTEXT` searches with CJK characters fail?

For `LIKE` searches, there is a very simple problem with binary string column types such as `BINARY` and `BLOB`: we must know where characters end. With multibyte character sets, different characters might have different octet lengths. For example, in `utf8`, `A` requires one byte but `𠂇` requires three bytes, as shown here:

```
+-----+-----+
| OCTET_LENGTH(_utf8 'A') | OCTET_LENGTH(_utf8 '𠂇') |
+-----+-----+
| 1 | 3 |
+-----+-----+
```

If we do not know where the first character in a string ends, we do not know where the second character begins, in which case even very simple searches such as `LIKE '_A%'` fail. The solution is to use a nonbinary string column type defined to have the proper CJK character set. For example: `mycol TEXT CHARACTER SET sjis`. Alternatively, convert to a CJK character set before comparing.

This is one reason why MySQL cannot permit encodings of nonexistent characters. If it is not strict about rejecting bad input, it has no way of knowing where characters end.

For `FULLTEXT` searches, we must know where words begin and end. With Western languages, this is rarely a problem because most (if not all) of these use an easy-to-identify word boundary: the space character. However, this is not usually the case with Asian writing. We could use arbitrary halfway measures, like assuming that all Han characters represent words, or (for Japanese) depending on changes from Katakana to Hiragana due to grammatical endings. However, the only sure solution requires a comprehensive word list, which means that we would have to include a dictionary in the server for each Asian language supported. This is simply not feasible.

#### A.11.12 How do I know whether character `x` is available in all character sets?

The majority of simplified Chinese and basic nonhalfwidth Japanese Kana characters appear in all CJK character sets. The following stored procedure accepts a `UCS-2` Unicode character, converts it to other character sets, and displays the results in hexadecimal.

```
DELIMITER //
CREATE PROCEDURE p_convert(ucs2_char CHAR(1) CHARACTER SET ucs2)
BEGIN
CREATE TABLE tj
 (ucs2 CHAR(1) character set ucs2,
 utf8 CHAR(1) character set utf8,
 big5 CHAR(1) character set big5,
 cp932 CHAR(1) character set cp932,
 eucjpms CHAR(1) character set eucjpms,
```

```

euckr CHAR(1) character set euckr,
gb2312 CHAR(1) character set gb2312,
gbk CHAR(1) character set gbk,
sjis CHAR(1) character set sjis,
ujis CHAR(1) character set ujis;

INSERT INTO tj (ucs2) VALUES (ucs2_char);

UPDATE tj SET utf8=ucs2,
 big5=ucs2,
 cp932=ucs2,
 eucjpms=ucs2,
 euckr=ucs2,
 gb2312=ucs2,
 gbk=ucs2,
 sjis=ucs2,
 ujis=ucs2;

/* If there are conversion problems, UPDATE produces warnings. */

SELECT hex(ucs2) AS ucs2,
 hex(utf8) AS utf8,
 hex(big5) AS big5,
 hex(cp932) AS cp932,
 hex(eucjpms) AS eucjpms,
 hex(euckr) AS euckr,
 hex(gb2312) AS gb2312,
 hex(gbk) AS gbk,
 hex(sjis) AS sjis,
 hex(ujis) AS ujis
 FROM tj;

DROP TABLE tj;

END//

DELIMITER ;

```

The input can be any single `ucs2` character, or it can be the code value (hexadecimal representation) of that character. For example, from Unicode's list of `ucs2` encodings and names (<http://www.unicode.org/Public/UNIDATA/UnicodeData.txt>), we know that the Katakana character *Pe* appears in all CJK character sets, and that its code value is `X'30DA'`. If we use this value as the argument to `p_convert()`, the result is as shown here:

| ucs2              | utf8                | big5              | cp932             | eucjpms           | euckr             | gb2312            | gbk               | sjis              | ujis              |
|-------------------|---------------------|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|
| <code>30DA</code> | <code>E3839A</code> | <code>C772</code> | <code>8379</code> | <code>A5DA</code> | <code>ABDA</code> | <code>A5DA</code> | <code>A5DA</code> | <code>8379</code> | <code>A5DA</code> |

Since none of the column values is `3F` (that is, the question mark character, `?`), we know that every conversion worked.

### A.11.13 Why do CJK strings sort incorrectly in Unicode? (I)

#### Note

The CJK sorting problems described here can occur for MySQL versions prior to MySQL 8.0. As of MySQL 8.0, they can be solved by using the `utf8mb4` character set and the `utf8mb4_ja_0900_as_cs` collation.

Sometimes people observe that the result of a `utf8_unicode_ci` or `ucs2_unicode_ci` search, or of an `ORDER BY` sort is not what they think a native would expect. Although we never rule out the possibility that there is a bug, we have found in the past that many people do not correctly read the standard table of weights for the Unicode Collation Algorithm. MySQL uses the tables found under <http://www.unicode.org/Public/UCA/>:

- UCA 4.0.0 table: <http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt>

This includes `xxx_unicode_ci` collations with no version number in the collation name.

- UCA 5.2.0 table: <http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt>

This includes collations with `_520_` in the collation name.

- UCA 9.0.0 table: <http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt>

This includes collations with `_0900_` in the collation name.

To handle newer UCA versions, we create new collations. We are very wary about changing ordering of existing collations because that affects indexes, which can bring about situations such as that reported in Bug #16526, illustrated as follows:

```
mysql> CREATE TABLE tj (s1 CHAR(1) CHARACTER SET utf8 COLLATE utf8_unicode_ci);
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO tj VALUES ('が'), ('か');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM tj WHERE s1 = 'が';
+-----+
| s1 |
+-----+
| が |
| か |
+-----+
```

The character in the first result row is not the one that we searched for. Why did MySQL retrieve it? First we look for the Unicode code point value, which is possible by reading the hexadecimal number for the `ucs2` version of the characters:

```
mysql> SELECT s1, HEX(CONVERT(s1 USING ucs2)) FROM tj;
+-----+-----+
| s1 | HEX(CONVERT(s1 USING ucs2)) |
+-----+-----+
| が | 304C |
| か | 304B |
+-----+-----+
```

Now we search for `304B` and `304C` in the `4.0.0 allkeys` table, and find these lines:

```
304B ; [.1E57.0020.000E.304B] # HIRAGANA LETTER KA
304C ; [.1E57.0020.000E.304B][.0000.0140.0002.3099] # HIRAGANA LETTER GA; QQCM
```

The official Unicode names (following the “#” mark) tell us the Japanese syllabary (Hiragana), the informal classification (letter, digit, or punctuation mark), and the Western identifier (`KA` or `GA`, which happen to be voiced and unvoiced components of the same letter pair). More importantly, the *primary weight* (the first hexadecimal number inside the square brackets) is `1E57` on both lines. For comparisons in both searching and sorting, MySQL pays attention to the primary weight only, ignoring all the other numbers. This means that we are sorting `が` and `か` correctly according to the Unicode specification. If we wanted to distinguish them, we'd have to use a non-UCA (Unicode Collation Algorithm) collation (`utf8_bin` or `utf8_general_ci`), or to compare the `HEX()` values, or use `ORDER BY CONVERT(s1 USING sjis)`. Being correct “according to Unicode” is not enough, of course: the person who submitted the bug was equally correct. To solve this, we need another collation for Japanese according to the JIS X 4061 standard, in which voiced/unvoiced letter pairs like `KA/GA` are distinguishable for ordering purposes.

#### A.11.14 Why do CJK strings sort incorrectly in Unicode? (II)

**Note**

The CJK sorting problems described here can occur for MySQL versions prior to MySQL 8.0. As of MySQL 8.0, they can be solved by using the `utf8mb4` character set and the `utf8mb4_ja_0900_as_cs` collation.

If you are using Unicode (`ucs2` or `utf8`), and you know what the Unicode sort order is (see [Section A.11, “MySQL 5.7 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”](#)), but MySQL still seems to sort your table incorrectly, first verify the character set in the table definition:

```
mysql> SHOW CREATE TABLE t\G
***** 1. row *****
Table: t
Create Table: CREATE TABLE `t` (
 `s1` char(1) CHARACTER SET ucs2 DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

Since the character set for the column `s1` appears to be correct (`ucs2`), check what information the `INFORMATION_SCHEMA.COLUMNS` table can provide about this column:

```
mysql> SELECT COLUMN_NAME, CHARACTER_SET_NAME, COLLATION_NAME
 FROM INFORMATION_SCHEMA.COLUMNS
 WHERE COLUMN_NAME = 's1'
 AND TABLE_NAME = 't';
+-----+-----+-----+
| COLUMN_NAME | CHARACTER_SET_NAME | COLLATION_NAME |
+-----+-----+-----+
| s1 | ucs2 | ucs2_general_ci |
+-----+-----+-----+
```

(See [Section 24.3.5, “The INFORMATION\\_SCHEMA COLUMNS Table”](#), for more information.)

You can see that the collation is `ucs2_general_ci` instead of `ucs2_unicode_ci`. The reason why this is so can be found using `SHOW CHARACTER SET`, as shown here:

```
mysql> SHOW CHARSET LIKE 'ucs2%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| ucs2 | UCS-2 Unicode | ucs2_general_ci | 2 |
+-----+-----+-----+-----+
```

For `ucs2` and `utf8`, the default collation is “general”. To specify a Unicode UCA collation, use `COLLATE ucs2_unicode_ci`, as shown in the preceding item.

### A.11.15 Why are my supplementary characters rejected by MySQL?

Supplementary characters lie outside the Unicode *Basic Multilingual Plane / Plane 0*. BMP characters have code point values between `U+0000` and `U+FFFF`. Supplementary characters have code point values between `U+10000` and `U+10FFFF`.

To store supplementary characters, you must use a character set that permits them:

- The `utf8` and `ucs2` character sets support BMP characters only.

The `utf8` character set permits only `UTF-8` characters that take up to three bytes. This has led to reports such as that found in Bug #12600, which we rejected as “not a bug”. With `utf8`, MySQL must truncate an input string when it encounters bytes that it does not understand. Otherwise, it is unknown how long the bad multibyte character is.

One possible workaround is to use `ucs2` instead of `utf8`, in which case the “bad” characters are changed to question marks. However, no truncation takes place. You can also change the data type to `BLOB` or `BINARY`, which perform no validity checking.

- The `utf8mb4`, `utf16`, `utf16le`, and `utf32` character sets support BMP characters, as well as supplementary characters outside the BMP.

#### A.11.16 Should “CJK” be “CJKV”?

No. The term “CJKV” (*Chinese Japanese Korean Vietnamese*) refers to Vietnamese character sets which contain Han (originally Chinese) characters. MySQL supports the modern Vietnamese script with Western characters, but does not support the old Vietnamese script using Han characters.

As of MySQL 5.6, there are Vietnamese collations for Unicode character sets, as described in [Section 10.10.1, “Unicode Character Sets”](#).

#### A.11.17 Does MySQL permit CJK characters to be used in database and table names?

Yes.

#### A.11.18 Where can I find translations of the MySQL Manual into Chinese, Japanese, and Korean?

The Japanese translation of the MySQL 5.6 manual can be downloaded from <https://dev.mysql.com/doc/>.

#### A.11.19 Where can I get help with CJK and related issues in MySQL?

The following resources are available:

- A listing of MySQL user groups can be found at <https://wikis.oracle.com/display/mysql>List+of+MySQL+User+Groups>.
- View feature requests relating to character set issues at <http://tinyurl.com/y6xcuf>.
- Visit the MySQL [Character Sets, Collation, Unicode Forum](#). <http://forums.mysql.com/> also provides foreign-language forums.

## A.12 MySQL 5.7 FAQ: Connectors & APIs

For common questions, issues, and answers relating to the MySQL Connectors and other APIs, see the following areas of the Manual:

- [Using C API Features](#)
- [Common Problems with MySQL and PHP](#)
- [Connector/ODBC Notes and Tips](#)
- [Connector/.NET Programming](#)
- [MySQL Connector/J 5.1 Developer Guide](#)

## A.13 MySQL 5.7 FAQ: C API, libmysql

Frequently asked questions about MySQL C API and libmysql.

|                                                                                     |      |
|-------------------------------------------------------------------------------------|------|

| A.13.6 How do I report bugs? .....                                                  | 4091 |

A.13.7 Is it possible to compile the library myself? ..... 4091

**A.13.1** What is “MySQL Native C API”? What are typical benefits and use cases?

libmysql is a C-based API that you can use in C applications to connect with the MySQL database server. It is also itself used as the foundation for drivers for standard database APIs like ODBC, Perl's DBI, and Python's DB API.

**A.13.2** Which version of libmysql should I use?

For MySQL 8.0, 5.7, 5.6, and 5.5, we recommend libmysql 8.0.

**A.13.3** What if I want to use the “NoSQL” X DevAPI?

For C-language and X DevApi Document Store for MySQL 8.0, we recommend MySQL Connector/C++. Connector/C++ 8.0 has compatible C headers. (This is not applicable to MySQL 5.7 or before.)

**A.13.4** How to I download libmysql?

- Linux: The Client Utilities Package is available from the [MySQL Community Server](#) download page.
- Repos: The Client Utilities Package is available from the [Yum](#), [APT](#), [SuSE repositories](#).
- Windows: The Client Utilities Package is available from [Windows Installer](#).

**A.13.5** Where is the documentation?

See [MySQL 5.7 C API Developer Guide](#).

**A.13.6** How do I report bugs?

Please report any bugs or inconsistencies you observe to our [Bugs Database](#). Select the C API Client as shown.

**A.13.7** Is it possible to compile the library myself?

Yes, you can download the libmysqlclient source code and compile it on your own. Here's an example:

```
$ git clone --depth 1 https://github.com/mysql/mysql-server
$ cd mysql-server
$ mkdir build
$ cd build
$ cmake .. -GNinja -DDOWNLOAD_BOOST=1 \
 -DWITH_BOOST=/tmp -DCMAKE_BUILD_TYPE=Release -DWITHOUT_SERVER=ON \
 -DWITH_SSL=system
$ ninja libmysqlclient.a
$ ls -la archive_output_directory/libmysqlclient.a
-rw-rw-r-- 1 kg kg 8,5M wrz 5 04:57 archive_output_directory/libmysqlclient.a
```

**Note**

This example uses <https://ninja-build.org/> as a build system instead of make.

## A.14 MySQL 5.7 FAQ: Replication

In the following section, we provide answers to questions that are most frequently asked about MySQL Replication.

A.14.1 Must the replica be connected to the source all the time? ..... 4092

|                                                                                                                                                                     |      |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| A.14.2 Must I enable networking on my source and replica to enable replication? .....                                                                               | 4092 |
| A.14.3 How do I know how late a replica is compared to the source? In other words, how do I<br>know the date of the last statement replicated by the replica? ..... | 4092 |
| A.14.4 How do I force the source to block updates until the replica catches up? .....                                                                               | 4092 |
| A.14.5 What issues should I be aware of when setting up two-way replication? .....                                                                                  | 4093 |
| A.14.6 How can I use replication to improve performance of my system? .....                                                                                         | 4093 |
| A.14.7 What should I do to prepare client code in my own applications to use performance-<br>enhancing replication? .....                                           | 4093 |
| A.14.8 When and how much can MySQL replication improve the performance of my system? ..                                                                             | 4093 |
| A.14.9 How can I use replication to provide redundancy or high availability? .....                                                                                  | 4094 |
| A.14.10 How do I tell whether a replication source server is using statement-based or row-based<br>binary logging format? .....                                     | 4095 |
| A.14.11 How do I tell a replica to use row-based replication? .....                                                                                                 | 4095 |
| A.14.12 How do I prevent <code>GRANT</code> and <code>REVOKE</code> statements from replicating to replica machines? ..                                             | 4095 |
| A.14.13 Does replication work on mixed operating systems (for example, the source runs on<br>Linux while replicas run on macOS and Windows)? .....                  | 4095 |
| A.14.14 Does replication work on mixed hardware architectures (for example, the source runs on<br>a 64-bit machine while replicas run on 32-bit machines)? .....    | 4095 |

**A.14.1** Must the replica be connected to the source all the time?

No, it does not. The replica can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a source/replica relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the replica is not guaranteed to be in synchrony with the source unless you take some special measures.

To ensure that catchup can occur for a replica that has been disconnected, you must not remove binary log files from the source that contain information that has not yet been replicated to the replicas. Asynchronous replication can work only if the replica is able to continue reading the binary log from the point where it last read events.

**A.14.2** Must I enable networking on my source and replica to enable replication?

Yes, networking must be enabled on the source and replica. If networking is not enabled, the replica cannot connect to the source and transfer the binary log. Verify that the `skip_networking` system variable has not been enabled in the configuration file for either server.

**A.14.3** How do I know how late a replica is compared to the source? In other words, how do I know the date of the last statement replicated by the replica?

Check the `Seconds_Behind_Master` column in the output from `SHOW REPLICAS | SLAVE STATUS`. See [Section 16.1.7.1, “Checking Replication Status”](#).

When the replication SQL thread executes an event read from the source, it modifies its own time to the event timestamp. (This is why `TIMESTAMP` is well replicated.) In the `Time` column in the output of `SHOW PROCESSLIST`, the number of seconds displayed for the replication SQL thread is the number of seconds between the timestamp of the last replicated event and the real time of the replica machine. You can use this to determine the date of the last replicated event. Note that if your replica has been disconnected from the source for one hour, and then reconnects, you may immediately see large `Time` values such as 3600 for the replication SQL thread in `SHOW PROCESSLIST`. This is because the replica is executing statements that are one hour old. See [Section 16.2.3, “Replication Threads”](#).

**A.14.4** How do I force the source to block updates until the replica catches up?

Use the following procedure:

1. On the source, execute these statements:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SHOW MASTER STATUS;
```

Record the replication coordinates (the current binary log file name and position) from the output of the `SHOW` statement.

2. On the replica, issue the following statement, where the arguments to the `MASTER_POS_WAIT()` function are the replication coordinate values obtained in the previous step:

```
mysql> SELECT MASTER_POS_WAIT('log_name', log_pos);
```

The `SELECT` statement blocks until the replica reaches the specified log file and position. At that point, the replica is in synchrony with the source and the statement returns.

3. On the source, issue the following statement to enable the source to begin processing updates again:

```
mysql> UNLOCK TABLES;
```

#### A.14.5 What issues should I be aware of when setting up two-way replication?

MySQL replication currently does not support any locking protocol between source and replica to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-source 1, and in the meantime, before it propagates to co-source 2, client B could make an update to co-source 2 that makes the update of client A work differently than it did on co-source 1. Thus, when the update of client A makes it to co-source 2, it produces tables that are different from what you have on co-source 1, even after all the updates from co-source 2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention because the updates originating on another server are serialized in one replication thread. Even this benefit might be offset by network delays.

#### A.14.6 How can I use replication to improve performance of my system?

Set up one server as the source and direct all writes to it. Then configure as many replicas as you have the budget and rackspace for, and distribute the reads among the source and the replicas. You can also start the replicas with the `--skip-innodb` option, enable the `low_priority_updates` system variable, and set the `delay_key_write` system variable to `ALL` to get speed improvements on the replica end. In this case, the replica uses nontransactional `MyISAM` tables instead of `InnoDB` tables to get more speed by eliminating transactional overhead.

#### A.14.7 What should I do to prepare client code in my own applications to use performance-enhancing replication?

See the guide to using replication as a scale-out solution, [Section 16.3.4, “Using Replication for Scale-Out”](#).

#### A.14.8 When and how much can MySQL replication improve the performance of my system?

MySQL replication is most beneficial for a system that processes frequent reads and infrequent writes. In theory, by using a single-source/multiple-replica setup, you can scale the system by adding more replicas until you either run out of network bandwidth, or your update load grows to the point that the source cannot handle it.

To determine how many replicas you can use before the added benefits begin to level out, and how much you can improve performance of your site, you must know your query patterns, and determine empirically by benchmarking the relationship between the throughput for reads and writes on a typical source and a typical replica. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system. Let `reads` and `writes` denote the number of reads and writes per second, respectively.

Let's say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that `reads` is  $1200 - 2 * \text{writes}$ . In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Suppose that the source and each replica have the same capacity, and that we have one source and  $N$  replicas. Then we have for each server (source or replica):

$$\text{reads} = 1200 - 2 * \text{writes}$$

$$\text{reads} = 9 * \text{writes} / (N + 1) \text{ (reads are split, but writes replicated to all replicas)}$$

$$9 * \text{writes} / (N + 1) + 2 * \text{writes} = 1200$$

$$\text{writes} = 1200 / (2 + 9/(N + 1))$$

The last equation indicates the maximum number of writes for  $N$  replicas, given a maximum possible read rate of 1,200 per second and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If  $N = 0$  (which means we have no replication), our system can handle about  $1200/11 = 109$  writes per second.
- If  $N = 1$ , we get up to 184 writes per second.
- If  $N = 8$ , we get up to 400 writes per second.
- If  $N = 17$ , we get up to 480 writes per second.
- Eventually, as  $N$  approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

These computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what happens on your system if you add  $N$  replicas. However, answering the following questions should help you decide whether and by how much replication may improve the performance of your system:

- What is the read/write ratio on your system?
- How much more write load can one server handle if you reduce the reads?
- For how many replicas do you have bandwidth available on your network?

#### A.14.9 How can I use replication to provide redundancy or high availability?

How you implement redundancy is entirely dependent on your application and circumstances. High-availability solutions (with automatic failover) require active monitoring and either custom scripts or third party tools to provide the failover support from the original MySQL server to the replica.

To handle the process manually, you should be able to switch from a failed source to a pre-configured replica by altering your application to talk to the new server or by adjusting the DNS for the MySQL server from the failed server to the new server.

For more information and some example solutions, see [Section 16.3.7, “Switching Sources During Failover”](#).

**A.14.10** How do I tell whether a replication source server is using statement-based or row-based binary logging format?

Check the value of the `binlog_format` system variable:

```
mysql> SHOW VARIABLES LIKE 'binlog_format';
```

The value shown is always one of `STATEMENT`, `ROW`, or `MIXED`. For `MIXED` mode, statement-based logging is used by default but replication switches automatically to row-based logging under certain conditions, such as unsafe statements. For information about when this may occur, see [Section 5.4.4.3, “Mixed Binary Logging Format”](#).

**A.14.11** How do I tell a replica to use row-based replication?

Replicas automatically know which format to use.

**A.14.12** How do I prevent `GRANT` and `REVOKE` statements from replicating to replica machines?

Start the server with the `--replicate-wild-ignore-table=mysql.%` option to ignore replication for tables in the `mysql` database.

**A.14.13** Does replication work on mixed operating systems (for example, the source runs on Linux while replicas run on macOS and Windows)?

Yes.

**A.14.14** Does replication work on mixed hardware architectures (for example, the source runs on a 64-bit machine while replicas run on 32-bit machines)?

Yes.

## A.15 MySQL 5.7 FAQ: MySQL Enterprise Thread Pool

|        |                                                                                                                              |      |
|--------|------------------------------------------------------------------------------------------------------------------------------|------|
| A.15.1 | What is the Thread Pool and what problem does it solve? .....                                                                | 4095 |
| A.15.2 | How does the Thread Pool limit and manage concurrent sessions and transactions for optimal performance and throughput? ..... | 4096 |
| A.15.3 | How is the Thread Pool different from the client side Connection Pool? .....                                                 | 4096 |
| A.15.4 | When should I use the Thread Pool? .....                                                                                     | 4096 |
| A.15.5 | Are there recommended Thread Pool configurations? .....                                                                      | 4096 |

**A.15.1** What is the Thread Pool and what problem does it solve?

The MySQL Thread Pool is a MySQL server plugin that extends the default connection-handling capabilities of the MySQL server to limit the number of concurrently executing statements/queries and transactions to ensure that each has sufficient CPU and memory resources to fulfill its task. For MySQL 5.7, the Thread Pool plugin is included in MySQL Enterprise Edition, a commercial product.

The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. The Thread Pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The Thread Pool plugin increases server performance by efficiently managing statement execution threads for large numbers of client connections, especially on modern multi-CPU/Core systems.

For more information, see [Section 5.5.3, “MySQL Enterprise Thread Pool”](#).

**A.15.2** How does the Thread Pool limit and manage concurrent sessions and transactions for optimal performance and throughput?

The Thread Pool uses a “divide and conquer” approach to limiting and balancing concurrency. Unlike the default connection handling of the MySQL Server, the Thread Pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. The Thread Pool then manages client connections within configurable thread groups, where they are prioritized and queued based on the nature of the work they were submitted to accomplish.

For more information, see [Section 5.5.3.3, “Thread Pool Operation”](#).

**A.15.3** How is the Thread Pool different from the client side Connection Pool?

The MySQL Connection Pool operates on the client side to ensure that a MySQL client does not constantly connect to and disconnect from the MySQL server. It is designed to cache idle connections in the MySQL client for use by other users as they are needed. This minimizes the overhead and expense of establishing and tearing down connections as queries are submitted to the MySQL server. The MySQL Connection Pool has no visibility as to the query handling capabilities or load of the back-end MySQL server. By contrast, the Thread Pool operates on the MySQL server side and is designed to manage the execution of inbound concurrent connections and queries as they are received from the client connections accessing the back-end MySQL database. Because of the separation of duties, the MySQL Connection Pool and Thread Pool are orthogonal and can be used independent of each other.

MySQL Connection Pooling via the MySQL Connectors is covered in [Chapter 27, Connectors and APIs](#).

**A.15.4** When should I use the Thread Pool?

There are a few rules of thumb to consider for optimal Thread Pool use cases:

The MySQL `Threads_running` variable keeps track of the number of concurrent statements currently executing in the MySQL Server. If this variable consistently exceeds a region where the server won’t operate optimally (usually going beyond 40 for InnoDB workloads), the Thread Pool should be beneficial, especially in extreme parallel overload situations.

If you are using the `innodb_thread_concurrency` to limit the number of concurrently executing statements, you should find that the Thread Pool solves the same problem, only better, by assigning connections to thread groups, then queuing executions based on transactional content, user defined designations, and so forth.

Lastly, if your workload comprises mainly short queries, the Thread Pool should be beneficial.

To learn more, see [Section 5.5.3.4, “Thread Pool Tuning”](#).

**A.15.5** Are there recommended Thread Pool configurations?

The Thread Pool has a number of user case driven configuration parameters that affect its performance. To learn about these and tips on tuning, see [Section 5.5.3.4, “Thread Pool Tuning”](#).

## A.16 MySQL 5.7 FAQ: InnoDB Change Buffer

|                                                                                                |      |

| A.16.5 How do I determine the current size of the change buffer? .....                         | 4097 |

|                                                                                |      |
|--------------------------------------------------------------------------------|------|
| A.16.6 When does change buffer merging occur? .....                            | 4097 |
| A.16.7 When is the change buffer flushed? .....                                | 4098 |
| A.16.8 When should the change buffer be used? .....                            | 4098 |
| A.16.9 When should the change buffer not be used? .....                        | 4098 |
| A.16.10 Where can I find additional information about the change buffer? ..... | 4098 |

#### A.16.1 What types of operations modify secondary indexes and result in change buffering?

`INSERT`, `UPDATE`, and `DELETE` operations can modify secondary indexes. If an affected index page is not in the buffer pool, the changes can be buffered in the change buffer.

#### A.16.2 What is the benefit of the `InnoDB` change buffer?

Buffering secondary index changes when secondary index pages are not in the buffer pool avoids expensive random access I/O operations that would be required to immediately read in affected index pages from disk. Buffered changes can be applied later, in batches, as pages are read into the buffer pool by other read operations.

#### A.16.3 Does the change buffer support other types of indexes?

No. The change buffer only supports secondary indexes. Clustered indexes, full-text indexes, and spatial indexes are not supported. Full-text indexes have their own caching mechanism.

#### A.16.4 How much space does `InnoDB` use for the change buffer?

Prior to the introduction of the `innodb_change_buffer_max_size` configuration option in MySQL 5.6, the maximum size of the on-disk change buffer in the system tablespace was 1/3 of the `InnoDB` buffer pool size.

In MySQL 5.6 and later, the `innodb_change_buffer_max_size` configuration option defines the maximum size of the change buffer as a percentage of the total buffer pool size. By default, `innodb_change_buffer_max_size` is set to 25. The maximum setting is 50.

`InnoDB` does not buffer an operation if it would cause the on-disk change buffer to exceed the defined limit.

Change buffer pages are not required to persist in the buffer pool and may be evicted by LRU operations.

#### A.16.5 How do I determine the current size of the change buffer?

The current size of the change buffer is reported by `SHOW ENGINE INNODB STATUS \G`, under the `INSERT BUFFER AND ADAPTIVE HASH INDEX` heading. For example:

```

INSERT BUFFER AND ADAPTIVE HASH INDEX

Ibuf: size 1, free list len 0, seg size 2, 0 merges
```

Relevant data points include:

- `size`: The number of pages used within the change buffer. Change buffer size is equal to `seg size - (1 + free list len)`. The `1 +` value represents the change buffer header page.
- `seg size`: The size of the change buffer, in pages.

For information about monitoring change buffer status, see [Section 14.5.2, “Change Buffer”](#).

#### A.16.6 When does change buffer merging occur?

- When a page is read into the buffer pool, buffered changes are merged upon completion of the read, before the page is made available.

- Change buffer merging is performed as a background task. The `innodb_io_capacity` parameter sets an upper limit on the I/O activity performed by InnoDB background tasks such as merging data from the change buffer.
- A change buffer merge is performed during crash recovery. Changes are applied from the change buffer (in the system tablespace) to leaf pages of secondary indexes as index pages are read into the buffer pool.
- The change buffer is fully durable and can survive a system crash. Upon restart, change buffer merge operations resume as part of normal operations.
- A full merge of the change buffer can be forced as part of a slow server shutdown using `--innodb-fast-shutdown=0`.

#### A.16.7 When is the change buffer flushed?

Updated pages are flushed by the same flushing mechanism that flushes the other pages that occupy the buffer pool.

#### A.16.8 When should the change buffer be used?

The change buffer is a feature designed to reduce random I/O to secondary indexes as indexes grow larger and no longer fit in the InnoDB buffer pool. Generally, the change buffer should be used when the entire data set does not fit into the buffer pool, when there is substantial DML activity that modifies secondary index pages, or when there are lots of secondary indexes that are regularly changed by DML activity.

#### A.16.9 When should the change buffer not be used?

You might consider disabling the change buffer if the entire data set fits within the InnoDB buffer pool, if you have relatively few secondary indexes, or if you are using solid-state storage, where random reads are about as fast as sequential reads. Before making configuration changes, it is recommended that you run tests using a representative workload to determine if disabling the change buffer provides any benefit.

#### A.16.10 Where can I find additional information about the change buffer?

See [Section 14.5.2, “Change Buffer”](#).

## A.17 MySQL 5.7 FAQ: InnoDB Data-at-Rest Encryption

|                                                                                                                                                |      |
|------------------------------------------------------------------------------------------------------------------------------------------------|------|
| A.17.1 Is data decrypted for users who are authorized to see it? .....                                                                         | 4099 |
| A.17.2 What is the overhead associated with InnoDB data-at-rest encryption? .....                                                              | 4099 |
| A.17.3 What are the encryption algorithms used with InnoDB data-at-rest encryption? .....                                                      | 4099 |
| A.17.4 Is it possible to use 3rd party encryption algorithms in place of the one provided by the InnoDB data-at-rest encryption feature? ..... | 4099 |
| A.17.5 Can indexed columns be encrypted? .....                                                                                                 | 4099 |
| A.17.6 What data types and data lengths does InnoDB data-at-rest encryption support? .....                                                     | 4099 |
| A.17.7 Does data remain encrypted on the network? .....                                                                                        | 4099 |
| A.17.8 Does database memory contain cleartext or encrypted data? .....                                                                         | 4099 |
| A.17.9 How do I know which data to encrypt? .....                                                                                              | 4099 |
| A.17.10 How is InnoDB data-at-rest encryption different from encryption functions MySQL already provides? .....                                | 4100 |
| A.17.11 Does the transportable tablespaces feature work with InnoDB data-at-rest encryption? ..                                                | 4100 |
| A.17.12 Does compression work with InnoDB data-at-rest encryption? .....                                                                       | 4100 |
| A.17.13 Can I use <code>mysqlpump</code> or <code>mysqldump</code> with encrypted tables? .....                                                | 4100 |
| A.17.14 How do I change (rotate, re-key) the master encryption key? .....                                                                      | 4100 |
| A.17.15 How do I migrate data from a cleartext InnoDB tablespace to an encrypted InnoDB tablespace? .....                                      | 4100 |

A.17.16 Can the [InnoDB](#) data-at-rest feature store the master encryption key in an external device using the PKSC11 interface? ..... 4100

**A.17.1** Is data decrypted for users who are authorized to see it?

Yes. [InnoDB](#) data-at-rest encryption is designed to transparently apply encryption within the database without impacting existing applications. Returning data in encrypted format would break most existing applications. [InnoDB](#) data-at-rest encryption provides the benefit of encryption without the overhead associated with traditional database encryption solutions, which would typically require expensive and substantial changes to applications, database triggers, and views.

**A.17.2** What is the overhead associated with [InnoDB](#) data-at-rest encryption?

There is no additional storage overhead. According to internal benchmarks, performance overhead amounts to a single digit percentage difference.

**A.17.3** What are the encryption algorithms used with [InnoDB](#) data-at-rest encryption?

[InnoDB](#) data-at-rest encryption supports the Advanced Encryption Standard (AES256) block-based encryption algorithm. It uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption.

**A.17.4** Is it possible to use 3rd party encryption algorithms in place of the one provided by the [InnoDB](#) data-at-rest encryption feature?

No, it is not possible to use other encryption algorithms. The provided encryption algorithm is broadly accepted.

**A.17.5** Can indexed columns be encrypted?

[InnoDB](#) data-at-rest encryption supports all indexes transparently.

**A.17.6** What data types and data lengths does [InnoDB](#) data-at-rest encryption support?

[InnoDB](#) data-at-rest encryption supports all supported data types. There is no data length limitation.

**A.17.7** Does data remain encrypted on the network?

Data encrypted by the [InnoDB](#) data-at-rest feature is decrypted when it is read from the tablespace file. Thus, if the data is on the network, it is in cleartext form. However, data on the network can be encrypted using MySQL network encryption, which encrypts data traveling to and from a database using SSL/TLS.

**A.17.8** Does database memory contain cleartext or encrypted data?

With [InnoDB](#) data-at-rest encryption, in-memory data is decrypted, which provides complete transparency.

**A.17.9** How do I know which data to encrypt?

Compliance with the PCI-DSS standard requires that credit card numbers (Primary Account Number, or 'PAN') be stored in encrypted form. Breach Notification Laws (for example, CA SB 1386, CA AB 1950, and similar laws in 43+ more US states) require encryption of first name, last name, driver license number, and other PII data. In early 2008, CA AB 1298 added medical and health insurance information to PII data. Additionally, industry specific privacy and security standards may require encryption of certain assets. For example, assets such as pharmaceutical research results, oil field exploration results, financial contracts, or personal data of law enforcement informants may require encryption. In the health care industry, the privacy of patient data, health records and X-ray images is of the highest importance.

**A.17.10** How is [InnoDB](#) data-at-rest encryption different from encryption functions MySQL already provides?

There are symmetric and asymmetric encryption APIs in MySQL that can be used to manually encrypt data within the database. However, the application must manage encryption keys and perform required encryption and decryption operations by calling API functions. [InnoDB](#) data-at-rest encryption requires no application changes, is transparent to end users, and provides automated, built-in key management.

**A.17.11** Does the transportable tablespaces feature work with [InnoDB](#) data-at-rest encryption?

Yes. It is supported for encrypted file-per-table tablespaces. For more information, see [Exporting Encrypted Tablespaces](#).

**A.17.12** Does compression work with [InnoDB](#) data-at-rest encryption?

Customers using [InnoDB](#) data-at-rest encryption receive the full benefit of compression because compression is applied before data blocks are encrypted.

**A.17.13** Can I use `mysqldump` or `mysqlimport` with encrypted tables?

Yes. Because these utilities create logical backups, the data dumped from encrypted tables is not encrypted.

**A.17.14** How do I change (rotate, re-key) the master encryption key?

[InnoDB](#) data-at-rest encryption uses a two tier key mechanism. When data-at-rest encryption is used, individual tablespace keys are stored in the header of the underlying tablespace data file. Tablespace keys are encrypted using the master encryption key. The master encryption key is generated when tablespace encryption is enabled, and is stored outside the database. The master encryption key is rotated using the `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement, which generates a new master encryption key, stores the key, and rotates the key into use.

**A.17.15** How do I migrate data from a cleartext [InnoDB](#) tablespace to an encrypted [InnoDB](#) tablespace?

Transferring data from one tablespace to another is not required. To encrypt data in an [InnoDB](#) file-per-table tablespace, run `ALTER TABLE tbl_name ENCRYPTION = 'Y'`. To encrypt a general tablespace or the `mysql` tablespace, run `ALTER TABLESPACE tablespace_name ENCRYPTION = 'Y'`. Encryption support for general tablespaces was introduced in MySQL 8.0.13. Encryption support for the `mysql` system tablespace is available as of MySQL 8.0.16.

**A.17.16** Can the [InnoDB](#) data-at-rest feature store the master encryption key in an external device using the PKSC11 interface?

Not at this time. Currently, the KMIP 1.1 protocol is supported with the `keyring_okv` plugin, which is available with MySQL Enterprise Edition.

## A.18 MySQL 5.7 FAQ: Virtualization Support

**A.18.1** Is MySQL supported on virtualized environments such as Oracle VM, VMWare, Docker, Microsoft Hyper-V, or others? ..... 4100**A.18.11** Is MySQL supported on virtualized environments such as Oracle VM, VMWare, Docker, Microsoft Hyper-V, or others?

MySQL is supported on virtualized environments, but is certified only for [Oracle VM](#). Contact Oracle Support for more information.

Be aware of potential problems when using virtualization software. The usual ones are related to performance, performance degradations, slowness, or unpredictability of disk, I/O, network, and memory.

---

# Appendix B Error Messages and Common Problems

## Table of Contents

|                                                        |      |
|--------------------------------------------------------|------|
| B.1 Error Message Sources and Elements .....           | 4101 |

| B.3.6 Table Definition-Related Issues .....            | 4131 |
| B.3.7 Known Issues in MySQL .....                      | 4133 |

This appendix describes the types of error information MySQL provides and how to obtain information about them. The final section is for troubleshooting. It describes common problems and errors that may occur and potential resolutions.

## Additional Resources

Other error-related documentation includes:

- Information about configuring where and how the server writes the error log: [Section 5.4.2, “The Error Log”](#)
- Information about the character set used for error messages: [Section 10.6, “Error Message Character Set”](#)
- Information about the language used for error messages: [Section 10.12, “Setting the Error Message Language”](#)
- Information about errors related to InnoDB: [Section 14.22.4, “InnoDB Error Handling”](#)
- Descriptions of the error messages that the MySQL server and client programs generate: [MySQL 5.7 Error Message Reference](#)

## B.1 Error Message Sources and Elements

This section discusses how error messages originate within MySQL and the elements they contain.

- [Error Message Sources](#)
- [Error Message Elements](#)

## Error Message Sources

Error messages can originate on the server side or the client side:

- On the server side, error messages may occur during the startup and shutdown processes, as a result of issues that occur during SQL statement execution, and so forth.
  - The MySQL server writes some error messages to its error log. These indicate issues of interest to database administrators or that require DBA action.
  - The server sends other error messages to client programs. These indicate issues pertaining only to a particular client. The MySQL client library takes errors received from the server and makes them available to the host client program.

- Client-side error messages are generated from within the MySQL client library, usually involving problems communicating with the server.

Example server-side error messages written to the error log:

- This message produced during the startup process provides a status or progress indicator:

```
2018-09-26T14:46:06.326016Z 0 [Note] Skipping generation of SSL
certificates as options related to SSL are specified.
```

- This message indicates an issue that requires DBA action:

```
2018-10-02T03:20:39.410387Z 0 [ERROR] Plugin 'InnoDB'
registration as a STORAGE ENGINE failed.
```

Example server-side error message sent to client programs, as displayed by the `mysql` client:

```
mysql> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Example client-side error message originating from within the client library, as displayed by the `mysql` client:

```
shell> mysql -h no-such-host
ERROR 2005 (HY000): Unknown MySQL server host 'no-such-host' (0)
```

Whether an error originates from within the client library or is received from the server, a MySQL client program may respond in varying ways. As just illustrated, the client may display the error message so the user can take corrective measures. The client may instead internally attempt to resolve or retry a failed operation, or take other action.

## Error Message Elements

When an error occurs, error information includes several elements: an error code, SQLSTATE value, and message string. These elements have the following characteristics:

- Error code: This value is numeric. It is MySQL-specific and is not portable to other database systems.

Each error number has a corresponding symbolic value. Examples:

- The symbol for server error number `1146` is `ER_NO_SUCH_TABLE`.
- The symbol for client error number `2005` is `CR_UNKNOWN_HOST`.

Error codes are stable across General Availability (GA) releases of a given MySQL series. Before a series reaches GA status, new codes may still be under development and are subject to change.

- SQLSTATE value: This value is a five-character string (for example, '`42S02`'). SQLSTATE values are taken from ANSI SQL and ODBC and are more standardized than the numeric error codes. The first two characters of an SQLSTATE value indicate the error class:

- Class = '`00`' indicates success.
- Class = '`01`' indicates a warning.
- Class = '`02`' indicates "not found." This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. This condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.
- Class > '`02`' indicates an exception.

For server-side errors, not all MySQL error numbers have corresponding SQLSTATE values. In these cases, '`HY000`' (general error) is used.

For client-side errors, the SQLSTATE value is always '[HY000](#)' (general error), so it is not meaningful for distinguishing one client error from another.

- Message string: This string provides a textual description of the error.

## B.2 Error Information Interfaces

Error messages can originate on the server side or the client side, and each error message includes an error code, SQLSTATE value, and message string, as described in [Section B.1, “Error Message Sources and Elements”](#). For lists of server-side, client-side, and global (shared between server and clients) errors, see [MySQL 5.7 Error Message Reference](#).

For error checking from within programs, use error code numbers or symbols, not error message strings. Message strings do not change often, but it is possible. Also, if the database administrator changes the language setting, that affects the language of message strings; see [Section 10.12, “Setting the Error Message Language”](#).

Error information in MySQL is available in the server error log, at the SQL level, from within client programs, and at the command line.

- [Error Log](#)
- [SQL Error Message Interface](#)
- [Client Error Message Interface](#)
- [Command-Line Error Message Interface](#)

### Error Log

On the server side, some messages are intended for the error log. For information about configuring where and how the server writes the log, see [Section 5.4.2, “The Error Log”](#).

Other server error messages are intended to be sent to client programs and are available as described in [Client Error Message Interface](#).

### SQL Error Message Interface

At the SQL level, there are several sources of error information in MySQL:

- SQL statement warning and error information is available through the `SHOW WARNINGS` and `SHOW ERRORS` statements. The `warning_count` system variable indicates the number of errors, warnings, and notes (with notes excluded if the `sql_notes` system variable is disabled). The `error_count` system variable indicates the number of errors. Its value excludes warnings and notes.
- The `GET DIAGNOSTICS` statement may be used to inspect the diagnostic information in the diagnostics area. See [Section 13.6.7.3, “GET DIAGNOSTICS Statement”](#).
- `SHOW SLAVE STATUS` statement output includes information about replication errors occurring on replica servers.
- `SHOW ENGINE INNODB STATUS` statement output includes information about the most recent foreign key error if a `CREATE TABLE` statement for an `InnoDB` table fails.

### Client Error Message Interface

Client programs receive errors from two sources:

- Errors that originate on the client side from within the MySQL client library.

- Errors that originate on the server side and are sent to the client by the server. These are received within the client library, which makes them available to the host client program.

Regardless of whether an error originates from within the client library or is received from the server, a MySQL client program obtains the error code, SQLSTATE value, message string, and other related information by calling C API functions in the client library:

- `mysql_errno()` returns the MySQL error code.
- `mysql_sqlstate()` returns the SQLSTATE value.
- `mysql_error()` returns the message string.
- `mysql_stmt_errno()`, `mysql_stmt_sqlstate()`, and `mysql_stmt_error()` are the corresponding error functions for prepared statements.
- `mysql_warning_count()` returns the number of errors, warnings, and notes for the most recent statement.

For descriptions of the client library error functions, see [MySQL 5.7 C API Developer Guide](#).

A MySQL client program may respond to an error in varying ways. The client may display the error message so the user can take corrective measures, internally attempt to resolve or retry a failed operation, or take other action. For example, (using the `mysql` client), a failure to connect to the server might result in this message:

```
shell> mysql -h no-such-host
ERROR 2005 (HY000): Unknown MySQL server host 'no-such-host' (0)
```

## Command-Line Error Message Interface

The `perror` program provides information from the command line about error numbers. See [Section 4.8.2, “perror — Display MySQL Error Message Information”](#).

```
shell> perror 1231
MySQL error code 1231 (ER_WRONG_VALUE_FOR_VAR): Variable '%-.64s' can't
be set to the value of '%-.200s'
```

For MySQL NDB Cluster errors, use `ndb_perror`. See [Section 21.4.17, “ndb\\_perror — Obtain NDB Error Message Information”](#).

```
shell> ndb_perror 323
NDB error code 323: Invalid nodegroup id, nodegroup already existing:
Permanent error: Application error
```

## B.3 Problems and Common Errors

This section lists some common problems and error messages that you may encounter. It describes how to determine the causes of the problems and what to do to solve them.

### B.3.1 How to Determine What Is Causing a Problem

When you run into a problem, the first thing you should do is to find out which program or piece of equipment is causing it:

- If you have one of the following symptoms, then it is probably a hardware problems (such as memory, motherboard, CPU, or hard disk) or kernel problem:
  - The keyboard does not work. This can normally be checked by pressing the Caps Lock key. If the Caps Lock light does not change, you have to replace your keyboard. (Before doing this, you should try to restart your computer and check all cables to the keyboard.)
  - The mouse pointer does not move.

- The machine does not answer to a remote machine's pings.
- Other programs that are not related to MySQL do not behave correctly.
- Your system restarted unexpectedly. (A faulty user-level program should never be able to take down your system.)

In this case, you should start by checking all your cables and run some diagnostic tool to check your hardware! You should also check whether there are any patches, updates, or service packs for your operating system that could likely solve your problem. Check also that all your libraries (such as `glibc`) are up to date.

It is always good to use a machine with ECC memory to discover memory problems early.

- If your keyboard is locked up, you may be able to recover by logging in to your machine from another machine and executing `kbd_mode -a`.
- Please examine your system log file (`/var/log/messages` or similar) for reasons for your problem. If you think the problem is in MySQL, you should also examine MySQL's log files. See [Section 5.4, "MySQL Server Logs"](#).
- If you do not think you have hardware problems, you should try to find out which program is causing problems. Try using `top`, `ps`, Task Manager, or some similar program, to check which program is taking all CPU or is locking the machine.
- Use `top`, `df`, or a similar program to check whether you are out of memory, disk space, file descriptors, or some other critical resource.
- If the problem is some runaway process, you can always try to kill it. If it does not want to die, there is probably a bug in the operating system.

If you have examined all other possibilities and concluded that the MySQL server or a MySQL client is causing the problem, it is time to create a bug report, see [Section 1.6, "How to Report Bugs or Problems"](#). In the bug report, try to give a complete description of how the system is behaving and what you think is happening. Also state why you think that MySQL is causing the problem. Take into consideration all the situations described in this chapter. State any problems exactly how they appear when you examine your system. Use the "copy and paste" method for any output and error messages from programs and log files.

Try to describe in detail which program is not working and all symptoms you see. We have in the past received many bug reports that state only "the system does not work." This provides us with no information about what could be the problem.

If a program fails, it is always useful to know the following information:

- Has the program in question made a segmentation fault (did it dump core)?
- Is the program taking up all available CPU time? Check with `top`. Let the program run for a while, it may simply be evaluating something computationally intensive.
- If the `mysqld` server is causing problems, can you get any response from it with `mysqladmin -u root ping` or `mysqladmin -u root processlist`?
- What does a client program say when you try to connect to the MySQL server? (Try with `mysql`, for example.) Does the client jam? Do you get any output from the program?

When sending a bug report, you should follow the outline described in [Section 1.6, "How to Report Bugs or Problems"](#).

### B.3.2 Common Errors When Using MySQL Programs

This section lists some errors that users frequently encounter when running MySQL programs. Although the problems show up when you try to run client programs, the solutions to many of the problems involves changing the configuration of the MySQL server.

### B.3.2.1 Access denied

An [Access denied](#) error can have many causes. Often the problem is related to the MySQL accounts that the server permits client programs to use when connecting. See [Section 6.2, “Access Control and Account Management”](#), and [Section 6.2.17, “Troubleshooting Problems Connecting to MySQL”](#).

### B.3.2.2 Can't connect to [local] MySQL server

A MySQL client on Unix can connect to the `mysqld` server in two different ways: By using a Unix socket file to connect through a file in the file system (default `/tmp/mysql.sock`), or by using TCP/IP, which connects through a port number. A Unix socket file connection is faster than TCP/IP, but can be used only when connecting to a server on the same computer. A Unix socket file is used if you do not specify a host name or if you specify the special host name `localhost`.

If the MySQL server is running on Windows, you can connect using TCP/IP. If the server is started with the `named_pipe` system variable enabled, you can also connect with named pipes if you run the client on the host where the server is running. The name of the named pipe is `MySQL` by default. If you do not give a host name when connecting to `mysqld`, a MySQL client first tries to connect to the named pipe. If that does not work, it connects to the TCP/IP port. You can force the use of named pipes on Windows by using `.` as the host name.

The error (2002) [Can't connect to ...](#) normally means that there is no MySQL server running on the system or that you are using an incorrect Unix socket file name or TCP/IP port number when trying to connect to the server. You should also check that the TCP/IP port you are using has not been blocked by a firewall or port blocking service.

The error (2003) [Can't connect to MySQL server on 'server' \(10061\)](#) indicates that the network connection has been refused. You should check that there is a MySQL server running, that it has network connections enabled, and that the network port you specified is the one configured on the server.

Start by checking whether there is a process named `mysqld` running on your server host. (Use `ps xa | grep mysqld` on Unix or the Task Manager on Windows.) If there is no such process, you should start the server. See [Section 2.10.2, “Starting the Server”](#).

If a `mysqld` process is running, you can check it by trying the following commands. The port number or Unix socket file name might be different in your setup. `host_ip` represents the IP address of the machine where the server is running.

```
shell> mysqladmin version
shell> mysqladmin variables
shell> mysqladmin -h `hostname` version variables
shell> mysqladmin -h `hostname` --port=3306 version
shell> mysqladmin -h host_ip version
shell> mysqladmin --protocol=SOCKET --socket=/tmp/mysql.sock version
```

Note the use of backticks rather than forward quotation marks with the `hostname` command; these cause the output of `hostname` (that is, the current host name) to be substituted into the `mysqladmin` command. If you have no `hostname` command or are running on Windows, you can manually type the host name of your machine (without backticks) following the `-h` option. You can also try `-h 127.0.0.1` to connect with TCP/IP to the local host.

Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with the `skip_networking` system variable enabled, it does not accept TCP/IP connections at all. If the server was started with the `bind_address` system variable

set to `127.0.0.1`, it listens for TCP/IP connections only locally on the loopback interface and does not accept remote connections.

Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or Windows Firewall may need to be configured not to block the MySQL port.

Here are some reasons the `Can't connect to local MySQL server` error might occur:

- `mysqld` is not running on the local host. Check your operating system's process list to ensure the `mysqld` process is present.
- You're running a MySQL server on Windows with many TCP/IP connections to it. If you're experiencing that quite often your clients get that error, you can find a workaround here: [Connection to MySQL Server Failing on Windows](#).
- Someone has removed the Unix socket file that `mysqld` uses (`/tmp/mysql.sock` by default). For example, you might have a `cron` job that removes old files from the `/tmp` directory. You can always run `mysqladmin version` to check whether the Unix socket file that `mysqladmin` is trying to use really exists. The fix in this case is to change the `cron` job to not remove `mysql.sock` or to place the socket file somewhere else. See [Section B.3.3.6, “How to Protect or Change the MySQL Unix Socket File”](#).
- You have started the `mysqld` server with the `--socket=/path/to/socket` option, but forgotten to tell client programs the new name of the socket file. If you change the socket path name for the server, you must also notify the MySQL clients. You can do this by providing the same `--socket` option when you run client programs. You also need to ensure that clients have permission to access the `mysql.sock` file. To find out where the socket file is, you can do:

```
shell> netstat -ln | grep mysql
```

See [Section B.3.3.6, “How to Protect or Change the MySQL Unix Socket File”](#).

- You are using Linux and one server thread has died (dumped core). In this case, you must kill the other `mysqld` threads (for example, with `kill`) before you can restart the MySQL server. See [Section B.3.3.3, “What to Do If MySQL Keeps Crashing”](#).
- The server or client program might not have the proper access privileges for the directory that holds the Unix socket file or the socket file itself. In this case, you must either change the access privileges for the directory or socket file so that the server and clients can access them, or restart `mysqld` with a `--socket` option that specifies a socket file name in a directory where the server can create it and where client programs can access it.

If you get the error message `Can't connect to MySQL server on some_host`, you can try the following things to find out what the problem is:

- Check whether the server is running on that host by executing `telnet some_host 3306` and pressing the Enter key a couple of times. (3306 is the default MySQL port number. Change the value if your server is listening to a different port.) If there is a MySQL server running and listening to the port, you should get a response that includes the server's version number. If you get an error such as `telnet: Unable to connect to remote host: Connection refused`, then there is no server running on the given port.
- If the server is running on the local host, try using `mysqladmin -h localhost variables` to connect using the Unix socket file. Verify the TCP/IP port number that the server is configured to listen to (it is the value of the `port` variable.)
- If you are running under Linux and Security-Enhanced Linux (SELinux) is enabled, see [Section 6.7, “SELinux”](#).

## Connection to MySQL Server Failing on Windows

When you're running a MySQL server on Windows with many TCP/IP connections to it, and you're experiencing that quite often your clients get a [Can't connect to MySQL server](#) error, the reason might be that Windows does not allow for enough ephemeral (short-lived) ports to serve those connections.

The purpose of `TIME_WAIT` is to keep a connection accepting packets even after the connection has been closed. This is because Internet routing can cause a packet to take a slow route to its destination and it may arrive after both sides have agreed to close. If the port is in use for a new connection, that packet from the old connection could break the protocol or compromise personal information from the original connection. The `TIME_WAIT` delay prevents this by ensuring that the port cannot be reused until after some time has been permitted for those delayed packets to arrive.

It is safe to reduce `TIME_WAIT` greatly on LAN connections because there is little chance of packets arriving at very long delays, as they could travel through the Internet with its comparatively large distances and latencies.

Windows permits ephemeral (short-lived) TCP ports to the user. After any port is closed it remains in `TIME_WAIT` status for 120 seconds. The port is not available again until this time expires. The default range of port numbers depends on the version of Windows, with a more limited number of ports in older versions:

- Windows through Server 2003: Ports in range 1025–5000
- Windows Vista, Server 2008, and newer: Ports in range 49152–65535

With a small stack of available TCP ports (5000) and a high number of TCP ports being open and closed over a short period of time along with the `TIME_WAIT` status you have a good chance for running out of ports. There are two ways to address this problem:

- Reduce the number of TCP ports consumed quickly by investigating connection pooling or persistent connections where possible
- Tune some settings in the Windows registry (see below)

### Important

The following procedure involves modifying the Windows registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore it if a problem occurs. For information about how to back up, restore, and edit the registry, view the following article in the Microsoft Knowledge Base: <http://support.microsoft.com/kb/256986/EN-US/>.

1. Start Registry Editor ([Regedt32.exe](#)).
2. Locate the following key in the registry:

HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

3. On the [Edit](#) menu, click [Add Value](#), and then add the following registry value:

|                         |
|-------------------------|
| Value Name: MaxUserPort |
| Data Type: REG_DWORD    |
| Value: 65534            |

This sets the number of ephemeral ports available to any user. The valid range is between 5000 and 65534 (decimal). The default value is 0x1388 (5000 decimal).

4. On the [Edit](#) menu, click [Add Value](#), and then add the following registry value:

|                               |
|-------------------------------|
| Value Name: TcpTimedWaitDelay |
| Data Type: REG_DWORD          |

```
Value: 30
```

This sets the number of seconds to hold a TCP port connection in `TIME_WAIT` state before closing. The valid range is between 30 and 300 decimal, although you may wish to check with Microsoft for the latest permitted values. The default value is 0x78 (120 decimal).

5. Quit Registry Editor.
6. Reboot the machine.

Note: Undoing the above should be as simple as deleting the registry entries you've created.

### B.3.2.3 Lost connection to MySQL server

There are three likely causes for this error message.

Usually it indicates network connectivity trouble and you should check the condition of your network if this error occurs frequently. If the error message includes "during query," this is probably the case you are experiencing.

Sometimes the "during query" form happens when millions of rows are being sent as part of one or more queries. If you know that this is happening, you should try increasing `net_read_timeout` from its default of 30 seconds to 60 seconds or longer, sufficient for the data transfer to complete.

More rarely, it can happen when the client is attempting the initial connection to the server. In this case, if your `connect_timeout` value is set to only a few seconds, you may be able to resolve the problem by increasing it to ten seconds, perhaps more if you have a very long distance or slow connection. You can determine whether you are experiencing this more uncommon cause by using `SHOW GLOBAL STATUS LIKE 'Aborted_connects'`. It increases by one for each initial connection attempt that the server aborts. You may see "reading authorization packet" as part of the error message; if so, that also suggests that this is the solution that you need.

If the cause is none of those just described, you may be experiencing a problem with `BLOB` values that are larger than `max_allowed_packet`, which can cause this error with some clients. Sometime you may see an `ER_NET_PACKET_TOO_LARGE` error, and that confirms that you need to increase `max_allowed_packet`.

### B.3.2.4 Password Fails When Entered Interactively

MySQL client programs prompt for a password when invoked with a `--password` or `-p` option that has no following password value:

```
shell> mysql -u user_name -p
Enter password:
```

On some systems, you may find that your password works when specified in an option file or on the command line, but not when you enter it interactively at the `Enter password:` prompt. This occurs when the library provided by the system to read passwords limits password values to a small number of characters (typically eight). That is a problem with the system library, not with MySQL. To work around it, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

### B.3.2.5 Too many connections

If clients encounter `Too many connections` errors when attempting to connect to the `mysqld` server, all available connections are in use by other clients.

The permitted number of connections is controlled by the `max_connections` system variable. To support more connections, set `max_connections` to a larger value.

`mysqld` actually permits `max_connections` + 1 client connections. The extra connection is reserved for use by accounts that have the `SUPER` privilege. By granting the privilege to administrators and

not to normal users (who should not need it), an administrator who also has the `PROCESS` privilege can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum number of unprivileged clients are connected. See [Section 13.7.5.29, “SHOW PROCESSLIST Statement”](#).

For more information about how the server handles client connections, see [Section 5.1.11.1, “Connection Interfaces”](#).

### B.3.2.6 Out of memory

If you issue a query using the `mysql` client program and receive an error like the following one, it means that `mysql` does not have enough memory to store the entire query result:

```
mysql: Out of memory at line 42, 'malloc.c'
mysql: needed 8136 byte (8k), memory in use: 12481367 bytes (12189k)
ERROR 2008: MySQL client ran out of memory
```

To remedy the problem, first check whether your query is correct. Is it reasonable that it should return so many rows? If not, correct the query and try again. Otherwise, you can invoke `mysql` with the `--quick` option. This causes it to use the `mysql_use_result()` C API function to retrieve the result set, which places less of a load on the client (but more on the server).

### B.3.2.7 MySQL server has gone away

This section also covers the related `Lost connection to server during query` error.

The most common reason for the `MySQL server has gone away` error is that the server timed out and closed the connection. In this case, you normally get one of the following error codes (which one you get is operating system-dependent).

| Error Code                        | Description                                                                                                                 |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>CR_SERVER_GONE_ERROR</code> | The client couldn't send a question to the server.                                                                          |
| <code>CR_SERVER_LOST</code>       | The client didn't get an error when writing to the server, but it didn't get a full answer (or any answer) to the question. |

By default, the server closes the connection after eight hours if nothing has happened. You can change the time limit by setting the `wait_timeout` variable when you start `mysqld`. See [Section 5.1.7, “Server System Variables”](#).

If you have a script, you just have to issue the query again for the client to do an automatic reconnection. This assumes that you have automatic reconnection in the client enabled (which is the default for the `mysql` command-line client).

Some other common reasons for the `MySQL server has gone away` error are:

- You (or the db administrator) has killed the running thread with a `KILL` statement or a `mysqladmin kill` command.
- You tried to run a query after closing the connection to the server. This indicates a logic error in the application that should be corrected.
- A client application running on a different host does not have the necessary privileges to connect to the MySQL server from that host.
- You got a timeout from the TCP/IP connection on the client side. This may happen if you have been using the commands: `mysql_options(..., MYSQL_OPT_READ_TIMEOUT,...)` or `mysql_options(..., MYSQL_OPT_WRITE_TIMEOUT,...)`. In this case increasing the timeout may help solve the problem.
- You have encountered a timeout on the server side and the automatic reconnection in the client is disabled (the `reconnect` flag in the `MYSQL` structure is equal to 0).

- You are using a Windows client and the server had dropped the connection (probably because `wait_timeout` expired) before the command was issued.

The problem on Windows is that in some cases MySQL does not get an error from the OS when writing to the TCP/IP connection to the server, but instead gets the error when trying to read the answer from the connection.

The solution to this is to either do a `mysql_ping()` on the connection if there has been a long time since the last query (this is what Connector/ODBC does) or set `wait_timeout` on the `mysqld` server so high that it in practice never times out.

- You can also get these errors if you send a query to the server that is incorrect or too large. If `mysqld` receives a packet that is too large or out of order, it assumes that something has gone wrong with the client and closes the connection. If you need big queries (for example, if you are working with big `BLOB` columns), you can increase the query limit by setting the server's `max_allowed_packet` variable, which has a default value of 4MB. You may also need to increase the maximum packet size on the client end. More information on setting the packet size is given in [Section B.3.2.8, “Packet Too Large”](#).

An `INSERT` or `REPLACE` statement that inserts a great many rows can also cause these sorts of errors. Either one of these statements sends a single request to the server irrespective of the number of rows to be inserted; thus, you can often avoid the error by reducing the number of rows sent per `INSERT` or `REPLACE`.

- It is also possible to see this error if host name lookups fail (for example, if the DNS server on which your server or network relies goes down). This is because MySQL is dependent on the host system for name resolution, but has no way of knowing whether it is working—from MySQL's point of view the problem is indistinguishable from any other network timeout.

You may also see the `MySQL server has gone away` error if MySQL is started with the `skip_networking` system variable enabled.

Another networking issue that can cause this error occurs if the MySQL port (default 3306) is blocked by your firewall, thus preventing any connections at all to the MySQL server.

- You can also encounter this error with applications that fork child processes, all of which try to use the same connection to the MySQL server. This can be avoided by using a separate connection for each child process.
- You have encountered a bug where the server died while executing the query.

You can check whether the MySQL server died and restarted by executing `mysqladmin version` and examining the server's uptime. If the client connection was broken because `mysqld` crashed and restarted, you should concentrate on finding the reason for the crash. Start by checking whether issuing the query again kills the server again. See [Section B.3.3.3, “What to Do If MySQL Keeps Crashing”](#).

You can obtain more information about lost connections by starting `mysqld` with the `log_error_verbosity` system variable set to 3. This logs some of the disconnection messages in the `hostname.err` file. See [Section 5.4.2, “The Error Log”](#).

If you want to create a bug report regarding this problem, be sure that you include the following information:

- Indicate whether the MySQL server died. You can find information about this in the server error log. See [Section B.3.3.3, “What to Do If MySQL Keeps Crashing”](#).
- If a specific query kills `mysqld` and the tables involved were checked with `CHECK TABLE` before you ran the query, can you provide a reproducible test case? See [Section 5.8, “Debugging MySQL”](#).
- What is the value of the `wait_timeout` system variable in the MySQL server? (`mysqladmin variables` gives you the value of this variable.)

- Have you tried to run `mysqld` with the general query log enabled to determine whether the problem query appears in the log? (See [Section 5.4.3, “The General Query Log”](#).)

See also [Section B.3.2.9, “Communication Errors and Aborted Connections”](#), and [Section 1.6, “How to Report Bugs or Problems”](#).

### B.3.2.8 Packet Too Large

A communication packet is a single SQL statement sent to the MySQL server, a single row that is sent to the client, or a binary log event sent from a source replication server to a replica.

The largest possible packet that can be transmitted to or from a MySQL 5.7 server or client is 1GB.

When a MySQL client or the `mysqld` server receives a packet bigger than `max_allowed_packet` bytes, it issues an `ER_NET_PACKET_TOO_LARGE` error and closes the connection. With some clients, you may also get a `Lost connection to MySQL server during query` error if the communication packet is too large.

Both the client and the server have their own `max_allowed_packet` variable, so if you want to handle big packets, you must increase this variable both in the client and in the server.

If you are using the `mysql` client program, its default `max_allowed_packet` variable is 16MB. To set a larger value, start `mysql` like this:

```
shell> mysql --max_allowed_packet=32M
```

That sets the packet size to 32MB.

The server's default `max_allowed_packet` value is 4MB. You can increase this if the server needs to handle big queries (for example, if you are working with big `BLOB` columns). For example, to set the variable to 16MB, start the server like this:

```
shell> mysqld --max_allowed_packet=16M
```

You can also use an option file to set `max_allowed_packet`. For example, to set the size for the server to 16MB, add the following lines in an option file:

```
[mysqld]
max_allowed_packet=16M
```

It is safe to increase the value of this variable because the extra memory is allocated only when needed. For example, `mysqld` allocates more memory only when you issue a long query or when `mysqld` must return a large result row. The small default value of the variable is a precaution to catch incorrect packets between the client and server and also to ensure that you do not run out of memory by using large packets accidentally.

You can also get strange problems with large packets if you are using large `BLOB` values but have not given `mysqld` access to enough memory to handle the query. If you suspect this is the case, try adding `ulimit -d 256000` to the beginning of the `mysqld_safe` script and restarting `mysqld`.

### B.3.2.9 Communication Errors and Aborted Connections

If connection problems occur such as communication errors or aborted connections, use these sources of information to diagnose problems:

- The error log. See [Section 5.4.2, “The Error Log”](#).
- The general query log. See [Section 5.4.3, “The General Query Log”](#).
- The `Aborted_xxx` and `Connection_errors_xxx` status variables. See [Section 5.1.9, “Server Status Variables”](#).

- The host cache, which is accessible using the Performance Schema `host_cache` table. See [Section 5.1.11.2, “DNS Lookups and the Host Cache”](#), and [Section 25.12.16.1, “The `host\_cache` Table”](#).

If the `log_error_verbosity` system variable is set to 3, you might find messages like this in your error log:

```
[Note] Aborted connection 854 to db: 'employees' user: 'josh'
```

If a client is unable even to connect, the server increments the `Aborted_connects` status variable. Unsuccessful connection attempts can occur for the following reasons:

- A client attempts to access a database but has no privileges for it.
- A client uses an incorrect password.
- A connection packet does not contain the right information.
- It takes more than `connect_timeout` seconds to obtain a connect packet. See [Section 5.1.7, “Server System Variables”](#).

If these kinds of things happen, it might indicate that someone is trying to break into your server! If the general query log is enabled, messages for these types of problems are logged to it.

If a client successfully connects but later disconnects improperly or is terminated, the server increments the `Aborted_clients` status variable, and logs an `Aborted connection` message to the error log. The cause can be any of the following:

- The client program did not call `mysql_close()` before exiting.
- The client had been sleeping more than `wait_timeout` or `interactive_timeout` seconds without issuing any requests to the server. See [Section 5.1.7, “Server System Variables”](#).
- The client program ended abruptly in the middle of a data transfer.

Other reasons for problems with aborted connections or aborted clients:

- The `max_allowed_packet` variable value is too small or queries require more memory than you have allocated for `mysqld`. See [Section B.3.2.8, “Packet Too Large”](#).
- Use of Ethernet protocol with Linux, both half and full duplex. Some Linux Ethernet drivers have this bug. You should test for this bug by transferring a huge file using FTP between the client and server machines. If a transfer goes in burst-pause-burst-pause mode, you are experiencing a Linux duplex syndrome. Switch the duplex mode for both your network card and hub/switch to either full duplex or to half duplex and test the results to determine the best setting.
- A problem with the thread library that causes interrupts on reads.
- Badly configured TCP/IP.
- Faulty Ethernets, hubs, switches, cables, and so forth. This can be diagnosed properly only by replacing hardware.

See also [Section B.3.2.7, “MySQL server has gone away”](#).

### B.3.2.10 The table is full

If a table-full error occurs, it may be that the disk is full or that the table has reached its maximum size. The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. See [Section 8.4.6, “Limits on Table Size”](#).

### B.3.2.11 Can't create/write to file

If you get an error of the following type for some queries, it means that MySQL cannot create a temporary file for the result set in the temporary directory:

```
Can't create/write to file '\\sqla3fe_0.ism'.
```

The preceding error is a typical message for Windows; the Unix message is similar.

One fix is to start `mysqld` with the `--tmpdir` option or to add the option to the `[mysqld]` section of your option file. For example, to specify a directory of `C:\temp`, use these lines:

```
[mysqld]
tmpdir=C:/temp
```

The `C:\temp` directory must exist and have sufficient space for the MySQL server to write to. See [Section 4.2.2.2, “Using Option Files”](#).

Another cause of this error can be permissions issues. Make sure that the MySQL server can write to the `tmpdir` directory.

Check also the error code that you get with `perror`. One reason the server cannot write to a table is that the file system is full:

```
shell> perror 28
OS error code 28: No space left on device
```

If you get an error of the following type during startup, it indicates that the file system or directory used for storing data files is write protected. Provided that the write error is to a test file, the error is not serious and can be safely ignored.

```
Can't create test file /usr/local/mysql/data/master.lower-test
```

### B.3.2.12 Commands out of sync

If you get `Commands out of sync; you can't run this command now` in your client code, you are calling client functions in the wrong order.

This can happen, for example, if you are using `mysql_use_result()` and try to execute a new query before you have called `mysql_free_result()`. It can also happen if you try to execute two queries that return data without calling `mysql_use_result()` or `mysql_store_result()` in between.

### B.3.2.13 Ignoring user

If you get the following error, it means that when `mysqld` was started or when it reloaded the grant tables, it found an account in the `user` table that had an invalid password.

```
Found wrong password for user 'some_user'@'some_host'; ignoring user
```

As a result, the account is simply ignored by the permission system.

The following list indicates possible causes of and fixes for this problem:

- You may be running a new version of `mysqld` with an old `user` table. Check whether the `Password` column of that table is shorter than 16 characters. If so, correct this condition by running `mysql_upgrade`.
- The account has an old password (eight characters long). Update the account in the `user` table to have a new password.
- You have specified a password in the `user` table without using the `PASSWORD( )` function. Use `mysql` to update the account in the `user` table with a new password, making sure to use the `PASSWORD( )` function:

```
mysql> UPDATE user SET Password=PASSWORD('new_password')
```

```
--> WHERE User='some_user' AND Host='some_host';
```

### B.3.2.14 Table 'tbl\_name' doesn't exist

If you get either of the following errors, it usually means that no table exists in the default database with the given name:

```
Table 'tbl_name' doesn't exist
Can't find file: 'tbl_name' (errno: 2)
```

In some cases, it may be that the table does exist but that you are referring to it incorrectly:

- Because MySQL uses directories and files to store databases and tables, database and table names are case-sensitive if they are located on a file system that has case-sensitive file names.
- Even for file systems that are not case-sensitive, such as on Windows, all references to a given table within a query must use the same lettercase.

You can check which tables are in the default database with `SHOW TABLES`. See [Section 13.7.5, “SHOW Statements”](#).

### B.3.2.15 Can't initialize character set

You might see an error like this if you have character set problems:

```
MySQL Connection Failed: Can't initialize character set charset_name
```

This error can have any of the following causes:

- The character set is a multibyte character set and you have no support for the character set in the client. In this case, you need to recompile the client by running `CMake` with the `-DDEFAULT_CHARSET=charset_name` or `-DWITH_EXTRA_CHARSETS=charset_name` option. See [Section 2.9.7, “MySQL Source-Configuration Options”](#).

All standard MySQL binaries are compiled with `-DWITH_EXTRA_CHARSETS=complex`, which enables support for all multibyte character sets. See [Section 2.9.7, “MySQL Source-Configuration Options”](#).

- The character set is a simple character set that is not compiled into `mysqld`, and the character set definition files are not in the place where the client expects to find them.

In this case, you need to use one of the following methods to solve the problem:

- Recompile the client with support for the character set. See [Section 2.9.7, “MySQL Source-Configuration Options”](#).
- Specify to the client the directory where the character set definition files are located. For many clients, you can do this with the `--character-sets-dir` option.
- Copy the character definition files to the path where the client expects them to be.

### B.3.2.16 File Not Found and Similar Errors

If you get `ERROR 'file_name' not found (errno: 23)`, `Can't open file: file_name (errno: 24)`, or any other error with `errno 23` or `errno 24` from MySQL, it means that you have not allocated enough file descriptors for the MySQL server. You can use the `perror` utility to get a description of what the error number means:

```
shell> perror 23
OS error code 23: File table overflow
shell> perror 24
OS error code 24: Too many open files
```

```
shell> perror 11
OS error code 11: Resource temporarily unavailable
```

The problem here is that `mysqld` is trying to keep open too many files simultaneously. You can either tell `mysqld` not to open so many files at once or increase the number of file descriptors available to `mysqld`.

To tell `mysqld` to keep open fewer files at a time, you can make the table cache smaller by reducing the value of the `table_open_cache` system variable (the default value is 64). This may not entirely prevent running out of file descriptors because in some circumstances the server may attempt to extend the cache size temporarily, as described in [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#). Reducing the value of `max_connections` also reduces the number of open files (the default value is 100).

To change the number of file descriptors available to `mysqld`, you can use the `--open-files-limit` option to `mysqld_safe` or set the `open_files_limit` system variable. See [Section 5.1.7, “Server System Variables”](#). The easiest way to set these values is to add an option to your option file. See [Section 4.2.2.2, “Using Option Files”](#). If you have an old version of `mysqld` that does not support setting the open files limit, you can edit the `mysqld_safe` script. There is a commented-out line `ulimit -n 256` in the script. You can remove the `#` character to uncomment this line, and change the number `256` to set the number of file descriptors to be made available to `mysqld`.

`--open-files-limit` and `ulimit` can increase the number of file descriptors, but only up to the limit imposed by the operating system. There is also a “hard” limit that can be overridden only if you start `mysqld_safe` or `mysqld` as `root` (just remember that you also need to start the server with the `--user` option in this case so that it does not continue to run as `root` after it starts up). If you need to increase the operating system limit on the number of file descriptors available to each process, consult the documentation for your system.

#### Note

If you run the `tcsh` shell, `ulimit` does not work! `tcsh` also reports incorrect values when you ask for the current limits. In this case, you should start `mysqld_safe` using `sh`.

### B.3.2.17 Table-Corruption Issues

If you have started `mysqld` with the `myisam_recover_options` system variable set, MySQL automatically checks and tries to repair `MyISAM` tables if they are marked as ‘not closed properly’ or ‘crashed’. If this happens, MySQL writes an entry in the `hostname.err` file ‘`Warning: Checking table ...`’ which is followed by `Warning: Repairing table` if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further.

When the server detects `MyISAM` table corruption, it writes additional information to the error log, such as the name and line number of the source file, and the list of threads accessing the table. Example: `Got an error from thread_id=1, mi_dynrec.c:368`. This is useful information to include in bug reports.

See also [Section 5.1.6, “Server Command Options”](#), and [Section 5.8.1.7, “Making a Test Case If You Experience Table Corruption”](#).

## B.3.3 Administration-Related Issues

### B.3.3.1 Problems with File Permissions

If you have problems with file permissions, the `UMASK` or `UMASK_DIR` environment variable might be set incorrectly when `mysqld` starts. For example, `mysqld` might issue the following error message when you create a table:

```
ERROR: Can't find file: 'path/with/filename.frm' (Errcode: 13)
```

The default `UMASK` and `UMASK_DIR` values are `0640` and `0750`, respectively. `mysqld` assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero. For example, setting `UMASK=0600` is equivalent to `UMASK=384` because `0600` octal is `384` decimal.

Assuming that you start `mysqld` using `mysqld_safe`, change the default `UMASK` value as follows:

```
UMASK=384 # = 600 in octal
export UMASK
mysqld_safe &
```

#### Note

An exception applies for the error log file if you start `mysqld` using `mysqld_safe`, which does not respect `UMASK`: `mysqld_safe` may create the error log file if it does not exist prior to starting `mysqld`, and `mysqld_safe` uses a umask set to a strict value of `0137`. If this is unsuitable, create the error file manually with the desired access mode prior to executing `mysqld_safe`.

By default, `mysqld` creates database directories with an access permission value of `0750`. To modify this behavior, set the `UMASK_DIR` variable. If you set its value, new directories are created with the combined `UMASK` and `UMASK_DIR` values. For example, to give group access to all new directories, start `mysqld_safe` as follows:

```
UMASK_DIR=504 # = 770 in octal
export UMASK_DIR
mysqld_safe &
```

For additional details, see [Section 4.9, “Environment Variables”](#).

### B.3.3.2 How to Reset the Root Password

If you have never assigned a `root` password for MySQL, the server does not require a password at all for connecting as `root`. However, this is insecure. For instructions on assigning a password, see [Section 2.10.4, “Securing the Initial MySQL Account”](#).

If you know the `root` password and want to change it, see [Section 13.7.1.1, “ALTER USER Statement”](#), and [Section 13.7.1.7, “SET PASSWORD Statement”](#).

If you assigned a `root` password previously but have forgotten it, you can assign a new password. The following sections provide instructions for Windows and Unix and Unix-like systems, as well as generic instructions that apply to any system.

#### Resetting the Root Password: Windows Systems

On Windows, use the following procedure to reset the password for the MySQL `'root'@'localhost'` account. To change the password for a `root` account with a different host name part, modify the instructions to use that host name.

1. Log on to your system as Administrator.
2. Stop the MySQL server if it is running. For a server that is running as a Windows service, go to the Services manager: From the **Start** menu, select **Control Panel**, then **Administrative Tools**, then **Services**. Find the MySQL service in the list and stop it.  
If your server is not running as a service, you may need to use the Task Manager to force it to stop.
3. Create a text file containing the password-assignment statement on a single line. Replace the password with the password that you want to use.

```
ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass';
```

4. Save the file. This example assumes that you name the file `C:\mysql-init.txt`.
5. Open a console window to get to the command prompt: From the **Start** menu, select **Run**, then enter `cmd` as the command to be run.
6. Start the MySQL server with the `init_file` system variable set to name the file (notice that the backslash in the option value is doubled):

```
C:\> cd "C:\Program Files\MySQL\MySQL Server 5.7\bin"
C:\> mysqld --init-file=C:\mysql-init.txt
```

If you installed MySQL to a different location, adjust the `cd` command accordingly.

The server executes the contents of the file named by the `init_file` system variable at startup, changing the `'root'@'localhost'` account password.

To have server output to appear in the console window rather than in a log file, add the `--console` option to the `mysqld` command.

If you installed MySQL using the MySQL Installation Wizard, you may need to specify a `--defaults-file` option. For example:

```
C:\> mysqld
 --defaults-file="C:\\ProgramData\\MySQL\\MySQL Server 5.7\\my.ini"
 --init-file=C:\\mysql-init.txt
```

The appropriate `--defaults-file` setting can be found using the Services Manager: From the **Start** menu, select **Control Panel**, then **Administrative Tools**, then **Services**. Find the MySQL service in the list, right-click it, and choose the **Properties** option. The **Path to executable** field contains the `--defaults-file` setting.

7. After the server has started successfully, delete `C:\mysql-init.txt`.

You should now be able to connect to the MySQL server as `root` using the new password. Stop the MySQL server and restart it normally. If you run the server as a service, start it from the Windows Services window. If you start the server manually, use whatever command you normally use.

If the `ALTER USER` statement fails to reset the password, try repeating the procedure using the following statements to modify the `user` table directly:

```
UPDATE mysql.user
 SET authentication_string = PASSWORD('MyNewPass'), password_expired = 'N'
 WHERE User = 'root' AND Host = 'localhost';
FLUSH PRIVILEGES;
```

## Resetting the Root Password: Unix and Unix-Like Systems

On Unix, use the following procedure to reset the password for the MySQL `'root'@'localhost'` account. To change the password for a `root` account with a different host name part, modify the instructions to use that host name.

The instructions assume that you start the MySQL server from the Unix login account that you normally use for running it. For example, if you run the server using the `mysql` login account, you should log in as `mysql` before using the instructions. Alternatively, you can log in as `root`, but in this case you *must* start `mysqld` with the `--user=mysql` option. If you start the server as `root` without using `--user=mysql`, the server may create `root`-owned files in the data directory, such as log files, and these may cause permission-related problems for future server startups. If that happens, you must either change the ownership of the files to `mysql` or remove them.

1. Log on to your system as the Unix user that the MySQL server runs as (for example, `mysql`).

2. Stop the MySQL server if it is running. Locate the `.pid` file that contains the server's process ID. The exact location and name of this file depend on your distribution, host name, and configuration. Common locations are `/var/lib/mysql/`, `/var/run/mysqld/`, and `/usr/local/mysql/data/`. Generally, the file name has an extension of `.pid` and begins with either `mysqld` or your system's host name.

Stop the MySQL server by sending a normal `kill` (not `kill -9`) to the `mysqld` process. Use the actual path name of the `.pid` file in the following command:

```
shell> kill `cat /mysql-data-directory/host_name.pid`
```

Use backticks (not forward quotation marks) with the `cat` command. These cause the output of `cat` to be substituted into the `kill` command.

3. Create a text file containing the password-assignment statement on a single line. Replace the password with the password that you want to use.

```
ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass';
```

4. Save the file. This example assumes that you name the file `/home/me/mysql-init`. The file contains the password, so do not save it where it can be read by other users. If you are not logged in as `mysql` (the user the server runs as), make sure that the file has permissions that permit `mysql` to read it.

5. Start the MySQL server with the `init_file` system variable set to name the file:

```
shell> mysqld --init-file=/home/me/mysql-init &
```

The server executes the contents of the file named by the `init_file` system variable at startup, changing the `'root'@'localhost'` account password.

Other options may be necessary as well, depending on how you normally start your server. For example, `--defaults-file` may be needed before the `init_file` argument.

6. After the server has started successfully, delete `/home/me/mysql-init`.

You should now be able to connect to the MySQL server as `root` using the new password. Stop the server and restart it normally.

If the `ALTER USER` statement fails to reset the password, try repeating the procedure using the following statements to modify the `user` table directly:

```
UPDATE mysql.user
 SET authentication_string = PASSWORD('MyNewPass'), password_expired = 'N'
 WHERE User = 'root' AND Host = 'localhost';
FLUSH PRIVILEGES;
```

## Resetting the Root Password: Generic Instructions

The preceding sections provide password-resetting instructions specifically for Windows and Unix and Unix-like systems. Alternatively, on any platform, you can reset the password using the `mysql` client (but this approach is less secure):

1. Stop the MySQL server if necessary, then restart it with the `--skip-grant-tables` option. This enables anyone to connect without a password and with all privileges, and disables account-management statements such as `ALTER USER` and `SET PASSWORD`. Because this is insecure, you might want to use `--skip-grant-tables` in conjunction with enabling the `skip_networking` system variable to prevent remote clients from connecting.
2. Connect to the MySQL server using the `mysql` client; no password is necessary because the server was started with `--skip-grant-tables`:

```
shell> mysql
```

3. In the `mysql` client, tell the server to reload the grant tables so that account-management statements work:

```
mysql> FLUSH PRIVILEGES;
```

Then change the '`root'@'localhost'` account password. Replace the password with the password that you want to use. To change the password for a `root` account with a different host name part, modify the instructions to use that host name.

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass';
```

You should now be able to connect to the MySQL server as `root` using the new password. Stop the server and restart it normally (without the `--skip-grant-tables` option and without enabling the `skip_networking` system variable).

If the `ALTER USER` statement fails to reset the password, try repeating the procedure using the following statements to modify the `user` table directly:

```
UPDATE mysql.user SET authentication_string = PASSWORD('MyNewPass')
WHERE User = 'root' AND Host = 'localhost';
FLUSH PRIVILEGES;
```

### B.3.3.3 What to Do If MySQL Keeps Crashing

Each MySQL version is tested on many platforms before it is released. This does not mean that there are no bugs in MySQL, but if there are bugs, they should be very few and can be hard to find. If you have a problem, it always helps if you try to find out exactly what crashes your system, because you have a much better chance of getting the problem fixed quickly.

First, you should try to find out whether the problem is that the `mysqld` server dies or whether your problem has to do with your client. You can check how long your `mysqld` server has been up by executing `mysqladmin version`. If `mysqld` has died and restarted, you may find the reason by looking in the server's error log. See [Section 5.4.2, “The Error Log”](#).

On some systems, you can find in the error log a stack trace of where `mysqld` died that you can resolve with the `resolve_stack_dump` program. See [Section 5.8, “Debugging MySQL”](#). Note that the variable values written in the error log may not always be 100% correct.

Many unexpected server exits are caused by corrupted data files or index files. MySQL updates the files on disk with the `write()` system call after every SQL statement and before the client is notified about the result. (This is not true if you are running with the `delay_key_write` system variable enabled, in which case data files are written but not index files.) This means that data file contents are safe even if `mysqld` crashes, because the operating system ensures that the unflushed data is written to disk. You can force MySQL to flush everything to disk after every SQL statement by starting `mysqld` with the `--flush` option.

The preceding means that normally you should not get corrupted tables unless one of the following happens:

- The MySQL server or the server host was killed in the middle of an update.
- You have found a bug in `mysqld` that caused it to die in the middle of an update.
- Some external program is manipulating data files or index files at the same time as `mysqld` without locking the table properly.
- You are running many `mysqld` servers using the same data directory on a system that does not support good file system locks (normally handled by the `lockd` lock manager), or you are running multiple servers with external locking disabled.
- You have a crashed data file or index file that contains very corrupt data that confused `mysqld`.

- You have found a bug in the data storage code. This isn't likely, but it is at least possible. In this case, you can try to change the storage engine to another engine by using `ALTER TABLE` on a repaired copy of the table.

Because it is very difficult to know why something is crashing, first try to check whether things that work for others result in an unexpected exit for you. Try the following things:

- Stop the `mysqld` server with `mysqladmin shutdown`, run `myisamchk --silent --force */*.MYI` from the data directory to check all `MyISAM` tables, and restart `mysqld`. This ensures that you are running from a clean state. See [Chapter 5, MySQL Server Administration](#).
- Start `mysqld` with the general query log enabled (see [Section 5.4.3, “The General Query Log”](#)). Then try to determine from the information written to the log whether some specific query kills the server. About 95% of all bugs are related to a particular query. Normally, this is one of the last queries in the log file just before the server restarts. See [Section 5.4.3, “The General Query Log”](#). If you can repeatedly kill MySQL with a specific query, even when you have checked all tables just before issuing it, then you have isolated the bug and should submit a bug report for it. See [Section 1.6, “How to Report Bugs or Problems”](#).
- Try to make a test case that we can use to repeat the problem. See [Section 5.8, “Debugging MySQL”](#).
- Try the `fork_big.pl` script. (It is located in the `tests` directory of source distributions.)
- Configuring MySQL for debugging makes it much easier to gather information about possible errors if something goes wrong. Reconfigure MySQL with the `-DWITH_DEBUG=1` option to `CMake` and then recompile. See [Section 5.8, “Debugging MySQL”](#).
- Make sure that you have applied the latest patches for your operating system.
- Use the `--skip-external-locking` option to `mysqld`. On some systems, the `lockd` lock manager does not work properly; the `--skip-external-locking` option tells `mysqld` not to use external locking. (This means that you cannot run two `mysqld` servers on the same data directory and that you must be careful if you use `myisamchk`. Nevertheless, it may be instructive to try the option as a test.)
- If `mysqld` appears to be running but not responding, try `mysqladmin -u root processlist`. Sometimes `mysqld` is not hung even though it seems unresponsive. The problem may be that all connections are in use, or there may be some internal lock problem. `mysqladmin -u root processlist` usually is able to make a connection even in these cases, and can provide useful information about the current number of connections and their status.
- Run the command `mysqladmin -i 5 status` or `mysqladmin -i 5 -r status` in a separate window to produce statistics while running other queries.
- Try the following:
  1. Start `mysqld` from `gdb` (or another debugger). See [Section 5.8, “Debugging MySQL”](#).
  2. Run your test scripts.
  3. Print the backtrace and the local variables at the three lowest levels. In `gdb`, you can do this with the following commands when `mysqld` has crashed inside `gdb`:

```
backtrace
info local
up
info local
up
info local
```

With `gdb`, you can also examine which threads exist with `info threads` and switch to a specific thread with `thread N`, where `N` is the thread ID.

- Try to simulate your application with a Perl script to force MySQL to exit or misbehave.
- Send a normal bug report. See [Section 1.6, “How to Report Bugs or Problems”](#). Be even more detailed than usual. Because MySQL works for many people, the crash might result from something that exists only on your computer (for example, an error that is related to your particular system libraries).
- If you have a problem with tables containing dynamic-length rows and you are using only `VARCHAR` columns (not `BLOB` or `TEXT` columns), you can try to change all `VARCHAR` to `CHAR` with `ALTER TABLE`. This forces MySQL to use fixed-size rows. Fixed-size rows take a little extra space, but are much more tolerant to corruption.

The current dynamic row code has been in use for several years with very few problems, but dynamic-length rows are by nature more prone to errors, so it may be a good idea to try this strategy to see whether it helps.

- Consider the possibility of hardware faults when diagnosing problems. Defective hardware can be the cause of data corruption. Pay particular attention to your memory and disk subsystems when troubleshooting hardware.

#### B.3.3.4 How MySQL Handles a Full Disk

This section describes how MySQL responds to disk-full errors (such as “no space left on device”), and to quota-exceeded errors (such as “write failed” or “user block limit reached”).

This section is relevant for writes to `MyISAM` tables. It also applies for writes to binary log files and binary log index file, except that references to “row” and “record” should be understood to mean “event.”

When a disk-full condition occurs, MySQL does the following:

- It checks once every minute to see whether there is enough space to write the current row. If there is enough space, it continues as if nothing had happened.
- Every 10 minutes it writes an entry to the log file, warning about the disk-full condition.

To alleviate the problem, take the following actions:

- To continue, you only have to free enough disk space to insert all records.
- Alternatively, to abort the thread, use `mysqladmin kill`. The thread is aborted the next time it checks the disk (in one minute).
- Other threads might be waiting for the table that caused the disk-full condition. If you have several “locked” threads, killing the one thread that is waiting on the disk-full condition enables the other threads to continue.

Exceptions to the preceding behavior are when you use `REPAIR TABLE` or `OPTIMIZE TABLE` or when the indexes are created in a batch after `LOAD DATA` or after an `ALTER TABLE` statement. All of these statements may create large temporary files that, if left to themselves, would cause big problems for the rest of the system. If the disk becomes full while MySQL is doing any of these operations, it removes the big temporary files and mark the table as crashed. The exception is that for `ALTER TABLE`, the old table is left unchanged.

#### B.3.3.5 Where MySQL Stores Temporary Files

On Unix, MySQL uses the value of the `TMPDIR` environment variable as the path name of the directory in which to store temporary files. If `TMPDIR` is not set, MySQL uses the system default, which is usually `/tmp`, `/var/tmp`, or `/usr/tmp`.

On Windows, MySQL checks in order the values of the `TMPDIR`, `TEMP`, and `TMP` environment variables. For the first one found to be set, MySQL uses it and does not check those remaining. If none of

If `TMPDIR`, `TEMP`, or `TMP` are set, MySQL uses the Windows system default, which is usually `C:\windows\temp\`.

If the file system containing your temporary file directory is too small, you can use the `mysqld --tmpdir` option to specify a directory in a file system where you have enough space.

The `--tmpdir` option can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (`:`) on Unix and semicolon characters (`;`) on Windows.

#### Note

To spread the load effectively, these paths should be located on different *physical* disks, not different partitions of the same disk.

If the MySQL server is acting as a replica, you can set the `slave_load_tmpdir` system variable to specify a separate directory for holding temporary files when replicating `LOAD DATA` statements. This directory should be in a disk-based file system (not a memory-based file system) so that the temporary files used to replicate `LOAD DATA` can survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process. However, replication can now continue after a restart if the temporary files have been removed.

MySQL arranges that temporary files are removed if `mysqld` is terminated. On platforms that support it (such as Unix), this is done by unlinking the file after opening it. The disadvantage of this is that the name does not appear in directory listings and you do not see a big temporary file that fills up the file system in which the temporary file directory is located. (In such cases, `lsof +L1` may be helpful in identifying large files associated with `mysqld`.)

When sorting (`ORDER BY` or `GROUP BY`), MySQL normally uses one or two temporary files. The maximum disk space required is determined by the following expression:

```
(length of what is sorted + sizeof(row pointer))
* number of matched rows
* 2
```

The row pointer size is usually four bytes, but may grow in the future for really big tables.

For some statements, MySQL creates temporary SQL tables that are not hidden and have names that begin with `#sql`.

Some `SELECT` queries create temporary SQL tables to hold intermediate results.

DDL operations that rebuild the table and are not performed online using the `ALGORITHM=INPLACE` technique create a temporary copy of the original table in the same directory as the original table.

Online DDL operations may use temporary log files for recording concurrent DML, temporary sort files when creating an index, and temporary intermediate tables files when rebuilding the table. For more information, see [Section 14.13.3, “Online DDL Space Requirements”](#).

`InnoDB` non-compressed, user-created temporary tables and on-disk internal temporary tables are created in a temporary tablespace file named `ibtmp1` in the MySQL data directory. For more information, see [Section 14.6.3.5, “The Temporary Tablespace”](#).

See also [Section 14.16.7, “InnoDB INFORMATION\\_SCHEMA Temporary Table Info Table”](#). [Orphan Temporary Tables](#).

### B.3.3.6 How to Protect or Change the MySQL Unix Socket File

The default location for the Unix socket file that the server uses for communication with local clients is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On some versions of Unix, anyone can delete files in the `/tmp` directory or other similar directories used for temporary files. If the socket file is located in such a directory on your system, this might cause problems.

On most versions of Unix, you can protect your `/tmp` directory so that files can be deleted only by their owners or the superuser (`root`). To do this, set the `sticky` bit on the `/tmp` directory by logging in as `root` and using the following command:

```
shell> chmod +t /tmp
```

You can check whether the `sticky` bit is set by executing `ls -ld /tmp`. If the last permission character is `t`, the bit is set.

Another approach is to change the place where the server creates the Unix socket file. If you do this, you should also let client programs know the new location of the file. You can specify the file location in several ways:

- Specify the path in a global or local option file. For example, put the following lines in `/etc/my.cnf`:

```
[mysqld]
socket=/path/to/socket

[client]
socket=/path/to/socket
```

See [Section 4.2.2.2, “Using Option Files”](#).

- Specify a `--socket` option on the command line to `mysqld_safe` and when you run client programs.
- Set the `MYSQL_UNIX_PORT` environment variable to the path of the Unix socket file.
- Recompile MySQL from source to use a different default Unix socket file location. Define the path to the file with the `MYSQL_UNIX_ADDR` option when you run `CMake`. See [Section 2.9.7, “MySQL Source-Configuration Options”](#).

You can test whether the new socket location works by attempting to connect to the server with this command:

```
shell> mysqladmin --socket=/path/to/socket version
```

### B.3.3.7 Time Zone Problems

If you have a problem with `SELECT NOW()` returning values in UTC and not your local time, you have to tell the server your current time zone. The same applies if `UNIX_TIMESTAMP()` returns the wrong value. This should be done for the environment in which the server runs (for example, in `mysqld_safe` or `mysql.server`). See [Section 4.9, “Environment Variables”](#).

You can set the time zone for the server with the `--timezone=timezone_name` option to `mysqld_safe`. You can also set it by setting the `TZ` environment variable before you start `mysqld`.

The permissible values for `--timezone` or `TZ` are system dependent. Consult your operating system documentation to see what values are acceptable.

## B.3.4 Query-Related Issues

### B.3.4.1 Case Sensitivity in String Searches

For nonbinary strings (`CHAR`, `VARCHAR`, `TEXT`), string searches use the collation of the comparison operands. For binary strings (`BINARY`, `VARBINARY`, `BLOB`), comparisons use the numeric values of the bytes in the operands; this means that for alphabetic characters, comparisons are case-sensitive.

A comparison between a nonbinary string and binary string is treated as a comparison of binary strings.

Simple comparison operations (`>=`, `>`, `=`, `<`, `<=`, sorting, and grouping) are based on each character's "sort value." Characters with the same sort value are treated as the same character. For example, if `e` and `é` have the same sort value in a given collation, they compare as equal.

The default character set and collation are `latin1` and `latin1_swedish_ci`, so nonbinary string comparisons are case-insensitive by default. This means that if you search with `col_name LIKE 'a %'`, you get all column values that start with `A` or `a`. To make this search case-sensitive, make sure that one of the operands has a case-sensitive or binary collation. For example, if you are comparing a column and a string that both have the `latin1` character set, you can use the `COLLATE` operator to cause either operand to have the `latin1_general_cs` or `latin1_bin` collation:

```
col_name COLLATE latin1_general_cs LIKE 'a%'
col_name LIKE 'a%' COLLATE latin1_general_cs
col_name COLLATE latin1_bin LIKE 'a%'
col_name LIKE 'a%' COLLATE latin1_bin
```

If you want a column always to be treated in case-sensitive fashion, declare it with a case-sensitive or binary collation. See [Section 13.1.18, "CREATE TABLE Statement"](#).

To cause a case-sensitive comparison of nonbinary strings to be case-insensitive, use `COLLATE` to name a case-insensitive collation. The strings in the following example normally are case-sensitive, but `COLLATE` changes the comparison to be case-insensitive:

```
mysql> SET @s1 = 'MySQL' COLLATE latin1_bin,
 -> @s2 = 'mysql' COLLATE latin1_bin;
mysql> SELECT @s1 = @s2;
+-----+
| @s1 = @s2 |
+-----+
| 0 |
+-----+
mysql> SELECT @s1 COLLATE latin1_swedish_ci = @s2;
+-----+
| @s1 COLLATE latin1_swedish_ci = @s2 |
+-----+
| 1 |
+-----+
```

A binary string is case-sensitive in comparisons. To compare the string as case-insensitive, convert it to a nonbinary string and use `COLLATE` to name a case-insensitive collation:

```
mysql> SET @s = BINARY 'MySQL';
mysql> SELECT @s = 'mysql';
+-----+
| @s = 'mysql' |
+-----+
| 0 |
+-----+
mysql> SELECT CONVERT(@s USING latin1) COLLATE latin1_swedish_ci = 'mysql';
+-----+
| CONVERT(@s USING latin1) COLLATE latin1_swedish_ci = 'mysql' |
+-----+
| 1 |
+-----+
```

To determine whether a value compares as a nonbinary or binary string, use the `COLLATION( )` function. This example shows that `VERSION()` returns a string that has a case-insensitive collation, so comparisons are case-insensitive:

```
mysql> SELECT COLLATION(VERSION());
+-----+
| COLLATION(VERSION()) |
+-----+
| utf8_general_ci |
+-----+
```

For binary strings, the collation value is `binary`, so comparisons are case-sensitive. One context in which you may see `binary` is for compression functions, which return binary strings as a general rule:

```
mysql> SELECT COLLATION(COMPRESS('x'));
+-----+
| COLLATION(COMPRESS('x')) |
+-----+
| binary
+-----+
```

To check the sort value of a string, the `WEIGHT_STRING()` may be helpful. See [Section 12.8, “String Functions and Operators”](#).

### B.3.4.2 Problems Using DATE Columns

The format of a `DATE` value is '`YYYY-MM-DD`'. According to standard SQL, no other format is permitted. You should use this format in `UPDATE` expressions and in the `WHERE` clause of `SELECT` statements. For example:

```
SELECT * FROM t1 WHERE date >= '2003-05-05' ;
```

As a convenience, MySQL automatically converts a date to a number if the date is used in numeric context and vice versa. MySQL also permits a “relaxed” string format when updating and in a `WHERE` clause that compares a date to a `DATE`, `DATETIME`, or `TIMESTAMP` column. “Relaxed” format means that any punctuation character may be used as the separator between parts. For example, '`2004-08-15`' and '`2004#08#15`' are equivalent. MySQL can also convert a string containing no separators (such as '`20040815`'), provided it makes sense as a date.

When you compare a `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` to a constant string with the `<`, `<=`, `=`, `>=`, `>`, or `BETWEEN` operators, MySQL normally converts the string to an internal long integer for faster comparison (and also for a bit more “relaxed” string checking). However, this conversion is subject to the following exceptions:

- When you compare two columns
- When you compare a `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` column to an expression
- When you use any comparison method other than those just listed, such as `IN` or `STRCMP()`.

For those exceptions, the comparison is done by converting the objects to strings and performing a string comparison.

To be on the safe side, assume that strings are compared as strings and use the appropriate string functions if you want to compare a temporal value to a string.

The special “zero” date '`0000-00-00`' can be stored and retrieved as '`0000-00-00`'. When a '`0000-00-00`' date is used through Connector/ODBC, it is automatically converted to `NULL` because ODBC cannot handle that kind of date.

Because MySQL performs the conversions just described, the following statements work (assume that `idate` is a `DATE` column):

```
INSERT INTO t1 (idate) VALUES (19970505);
INSERT INTO t1 (idate) VALUES ('19970505');
INSERT INTO t1 (idate) VALUES ('97-05-05');
INSERT INTO t1 (idate) VALUES ('1997.05.05');
INSERT INTO t1 (idate) VALUES ('1997 05 05');
INSERT INTO t1 (idate) VALUES ('0000-00-00');

SELECT idate FROM t1 WHERE idate >= '1997-05-05';
SELECT idate FROM t1 WHERE idate >= 19970505;
SELECT MOD(idate,100) FROM t1 WHERE idate >= 19970505;
SELECT idate FROM t1 WHERE idate >= '19970505';
```

However, the following statement does not work:

```
SELECT idate FROM t1 WHERE STRCMP(idate, '20030505')=0;
```

`STRCMP()` is a string function, so it converts `idate` to a string in '`YYYY-MM-DD`' format and performs a string comparison. It does not convert '`20030505`' to the date '`2003-05-05`' and perform a date comparison.

If you enable the `ALLOW_INVALID_DATES` SQL mode, MySQL permits you to store dates that are given only limited checking: MySQL requires only that the day is in the range from 1 to 31 and the month is in the range from 1 to 12. This makes MySQL very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation).

MySQL permits you to store dates where the day or month and day are zero. This is convenient if you want to store a birthdate in a `DATE` column and you know only part of the date. To disallow zero month or day parts in dates, enable the `NO_ZERO_IN_DATE` mode.

MySQL permits you to store a “zero” value of '`0000-00-00`' as a “dummy date.” This is in some cases more convenient than using `NULL` values. If a date to be stored in a `DATE` column cannot be converted to any reasonable value, MySQL stores '`0000-00-00`'. To disallow '`0000-00-00`', enable the `NO_ZERO_DATE` mode.

To have MySQL check all dates and accept only legal dates (unless overridden by `IGNORE`), set the `sql_mode` system variable to "`NO_ZERO_IN_DATE,NO_ZERO_DATE`".

### B.3.4.3 Problems with NULL Values

The concept of the `NULL` value is a common source of confusion for newcomers to SQL, who often think that `NULL` is the same thing as an empty string '`'`'. This is not the case. For example, the following statements are completely different:

```
mysql> INSERT INTO my_table (phone) VALUES (NULL);
mysql> INSERT INTO my_table (phone) VALUES ('');
```

Both statements insert a value into the `phone` column, but the first inserts a `NULL` value and the second inserts an empty string. The meaning of the first can be regarded as “phone number is not known” and the meaning of the second can be regarded as “the person is known to have no phone, and thus no phone number.”

To help with `NULL` handling, you can use the `IS NULL` and `IS NOT NULL` operators and the `IFNULL()` function.

In SQL, the `NULL` value is never true in comparison to any other value, even `NULL`. An expression that contains `NULL` always produces a `NULL` value unless otherwise indicated in the documentation for the operators and functions involved in the expression. All columns in the following example return `NULL`:

```
mysql> SELECT NULL, 1+NULL, CONCAT('Invisible',NULL);
```

To search for column values that are `NULL`, you cannot use an `expr = NULL` test. The following statement returns no rows, because `expr = NULL` is never true for any expression:

```
mysql> SELECT * FROM my_table WHERE phone = NULL;
```

To look for `NULL` values, you must use the `IS NULL` test. The following statements show how to find the `NULL` phone number and the empty phone number:

```
mysql> SELECT * FROM my_table WHERE phone IS NULL;
mysql> SELECT * FROM my_table WHERE phone = '';
```

See [Section 3.3.4.6, “Working with NULL Values”](#), for additional information and examples.

You can add an index on a column that can have `NULL` values if you are using the `MyISAM`, `InnoDB`, or `MEMORY` storage engine. Otherwise, you must declare an indexed column `NOT NULL`, and you cannot insert `NULL` into the column.

When reading data with `LOAD DATA`, empty or missing columns are updated with '''. To load a `NULL` value into a column, use `\N` in the data file. The literal word `NULL` may also be used under some circumstances. See [Section 13.2.6, “LOAD DATA Statement”](#).

When using `DISTINCT`, `GROUP BY`, or `ORDER BY`, all `NULL` values are regarded as equal.

When using `ORDER BY`, `NULL` values are presented first, or last if you specify `DESC` to sort in descending order.

Aggregate (group) functions such as `COUNT()`, `MIN()`, and `SUM()` ignore `NULL` values. The exception to this is `COUNT(*)`, which counts rows and not individual column values. For example, the following statement produces two counts. The first is a count of the number of rows in the table, and the second is a count of the number of non-`NULL` values in the `age` column:

```
mysql> SELECT COUNT(*), COUNT(age) FROM person;
```

For some data types, MySQL handles `NULL` values specially. If you insert `NULL` into a `TIMESTAMP` column, the current date and time is inserted. If you insert `NULL` into an integer or floating-point column that has the `AUTO_INCREMENT` attribute, the next number in the sequence is inserted.

#### B.3.4.4 Problems with Column Aliases

An alias can be used in a query select list to give a column a different name. You can use the alias in `GROUP BY`, `ORDER BY`, or `HAVING` clauses to refer to the column:

```
SELECT SQRT(a*b) AS root FROM tbl_name
 GROUP BY root HAVING root > 0;
SELECT id, COUNT(*) AS cnt FROM tbl_name
 GROUP BY id HAVING cnt > 0;
SELECT id AS 'Customer identity' FROM tbl_name;
```

Standard SQL disallows references to column aliases in a `WHERE` clause. This restriction is imposed because when the `WHERE` clause is evaluated, the column value may not yet have been determined. For example, the following query is illegal:

```
SELECT id, COUNT(*) AS cnt FROM tbl_name
 WHERE cnt > 0 GROUP BY id;
```

The `WHERE` clause determines which rows should be included in the `GROUP BY` clause, but it refers to the alias of a column value that is not known until after the rows have been selected, and grouped by the `GROUP BY`.

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```
SELECT 1 AS `one`, 2 AS 'two';
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal. For example, this statement groups by the values in column `id`, referenced using the alias ``a``:

```
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name
 GROUP BY `a`;
```

This statement groups by the literal string `'a'` and does not work as expected:

```
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name
 GROUP BY 'a';
```

#### B.3.4.5 Rollback Failure for Nontransactional Tables

If you receive the following message when trying to perform a `ROLLBACK`, it means that one or more of the tables you used in the transaction do not support transactions:

```
Warning: Some non-transactional changed tables couldn't be rolled back
```

These nontransactional tables are not affected by the `ROLLBACK` statement.

If you were not deliberately mixing transactional and nontransactional tables within the transaction, the most likely cause for this message is that a table you thought was transactional actually is not. This can happen if you try to create a table using a transactional storage engine that is not supported by your `mysqld` server (or that was disabled with a startup option). If `mysqld` does not support a storage engine, it instead creates the table as a `MyISAM` table, which is nontransactional.

You can check the storage engine for a table by using either of these statements:

```
SHOW TABLE STATUS LIKE 'tbl_name';
SHOW CREATE TABLE tbl_name;
```

See [Section 13.7.5.36, “SHOW TABLE STATUS Statement”](#), and [Section 13.7.5.10, “SHOW CREATE TABLE Statement”](#).

To check which storage engines your `mysqld` server supports, use this statement:

```
SHOW ENGINES;
```

See [Section 13.7.5.16, “SHOW ENGINES Statement”](#) for full details.

#### B.3.4.6 Deleting Rows from Related Tables

If the total length of the `DELETE` statement for `related_table` is more than 1MB (the default value of the `max_allowed_packet` system variable), you should split it into smaller parts and execute multiple `DELETE` statements. You probably get the fastest `DELETE` by specifying only 100 to 1,000 `related_column` values per statement if the `related_column` is indexed. If the `related_column` isn't indexed, the speed is independent of the number of arguments in the `IN` clause.

#### B.3.4.7 Solving Problems with No Matching Rows

If you have a complicated query that uses many tables but that returns no rows, you should use the following procedure to find out what is wrong:

1. Test the query with `EXPLAIN` to check whether you can find something that is obviously wrong. See [Section 13.8.2, “EXPLAIN Statement”](#).
2. Select only those columns that are used in the `WHERE` clause.
3. Remove one table at a time from the query until it returns some rows. If the tables are large, it is a good idea to use `LIMIT 10` with the query.
4. Issue a `SELECT` for the column that should have matched a row against the table that was last removed from the query.
5. If you are comparing `FLOAT` or `DOUBLE` columns with numbers that have decimals, you cannot use equality (`=`) comparisons. This problem is common in most computer languages because not all floating-point values can be stored with exact precision. In some cases, changing the `FLOAT` to a `DOUBLE` fixes this. See [Section B.3.4.8, “Problems with Floating-Point Values”](#).
6. If you still cannot figure out what is wrong, create a minimal test that can be run with `mysql test < query.sql` that shows your problems. You can create a test file by dumping the tables with `mysqldump --quick db_name tbl_name_1 ... tbl_name_n > query.sql`. Open the file in an editor, remove some insert lines (if there are more than needed to demonstrate the problem), and add your `SELECT` statement at the end of the file.

Verify that the test file demonstrates the problem by executing these commands:

```
shell> mysqladmin create test2
shell> mysql test2 < query.sql
```

Attach the test file to a bug report, which you can file using the instructions in [Section 1.6, “How to Report Bugs or Problems”](#).

### B.3.4.8 Problems with Floating-Point Values

Floating-point numbers sometimes cause confusion because they are approximate and not stored as exact values. A floating-point value as written in an SQL statement may not be the same as the value represented internally. Attempts to treat floating-point values as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. The `FLOAT` and `DOUBLE` data types are subject to these issues. For `DECIMAL` columns, MySQL performs operations with a precision of 65 decimal digits, which should solve most common inaccuracy problems.

The following example uses `DOUBLE` to demonstrate how calculations that are done using floating-point operations are subject to floating-point error.

```
mysql> CREATE TABLE t1 (i INT, d1 DOUBLE, d2 DOUBLE);
mysql> INSERT INTO t1 VALUES (1, 101.40, 21.40), (1, -80.00, 0.00),
 -> (2, 0.00, 0.00), (2, -13.20, 0.00), (2, 59.60, 46.40),
 -> (2, 30.40, 30.40), (3, 37.00, 7.40), (3, -29.60, 0.00),
 -> (4, 60.00, 15.40), (4, -10.60, 0.00), (4, -34.00, 0.00),
 -> (5, 33.00, 0.00), (5, -25.80, 0.00), (5, 0.00, 7.20),
 -> (6, 0.00, 0.00), (6, -51.40, 0.00);

mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b
 -> FROM t1 GROUP BY i HAVING a <> b;

+----+----+----+
| i | a | b |
+----+----+----+
| 1 | 21.4 | 21.4 |
| 2 | 76.8 | 76.8 |
| 3 | 7.4 | 7.4 |
| 4 | 15.4 | 15.4 |
| 5 | 7.2 | 7.2 |
| 6 | -51.4 | 0 |
+----+----+----+
```

The result is correct. Although the first five records look like they should not satisfy the comparison (the values of `a` and `b` do not appear to be different), they may do so because the difference between the numbers shows up around the tenth decimal or so, depending on factors such as computer architecture or the compiler version or optimization level. For example, different CPUs may evaluate floating-point numbers differently.

If columns `d1` and `d2` had been defined as `DECIMAL` rather than `DOUBLE`, the result of the `SELECT` query would have contained only one row—the last one shown above.

The correct way to do floating-point number comparison is to first decide on an acceptable tolerance for differences between the numbers and then do the comparison against the tolerance value. For example, if we agree that floating-point numbers should be regarded the same if they are same within a precision of one in ten thousand (0.0001), the comparison should be written to find differences larger than the tolerance value:

```
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
 -> GROUP BY i HAVING ABS(a - b) > 0.0001;
+----+----+----+
| i | a | b |
+----+----+----+
| 6 | -51.4 | 0 |
+----+----+----+
1 row in set (0.00 sec)
```

Conversely, to get rows where the numbers are the same, the test should find differences within the tolerance value:

```
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
```

```
--> GROUP BY i HAVING ABS(a - b) <= 0.0001;
+-----+-----+
| i | a | b |
+-----+-----+
| 1 | 21.4 | 21.4 |
| 2 | 76.8 | 76.8 |
| 3 | 7.4 | 7.4 |
| 4 | 15.4 | 15.4 |
| 5 | 7.2 | 7.2 |
+-----+-----+
5 rows in set (0.03 sec)
```

Floating-point values are subject to platform or implementation dependencies. Suppose that you execute the following statements:

```
CREATE TABLE t1(c1 FLOAT(53,0), c2 FLOAT(53,0));
INSERT INTO t1 VALUES('1e+52','-1e+52');
SELECT * FROM t1;
```

On some platforms, the `SELECT` statement returns `inf` and `-inf`. On others, it returns `0` and `-0`.

An implication of the preceding issues is that if you attempt to create a replica by dumping table contents with `mysqldump` on the source and reloading the dump file into the replica, tables containing floating-point columns might differ between the two hosts.

## B.3.5 Optimizer-Related Issues

MySQL uses a cost-based optimizer to determine the best way to resolve a query. In many cases, MySQL can calculate the best possible query plan, but sometimes MySQL does not have enough information about the data at hand and has to make “educated” guesses about the data.

For the cases when MySQL does not do the “right” thing, tools that you have available to help MySQL are:

- Use the `EXPLAIN` statement to get information about how MySQL processes a query. To use it, just add the keyword `EXPLAIN` to the front of your `SELECT` statement:

```
mysql> EXPLAIN SELECT * FROM t1, t2 WHERE t1.i = t2.i;
```

`EXPLAIN` is discussed in more detail in [Section 13.8.2, “EXPLAIN Statement”](#).

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See [Section 13.7.2.1, “ANALYZE TABLE Statement”](#).
- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

```
SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
WHERE t1.col_name=t2.col_name;
```

`USE INDEX` and `IGNORE INDEX` may also be useful. See [Section 8.9.4, “Index Hints”](#).

- Global and table-level `STRAIGHT_JOIN`. See [Section 13.2.9, “SELECT Statement”](#).
- You can tune global or thread-specific system variables. For example, start `mysqld` with the `--max-seeks-for-key=1000` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See [Section 5.1.7, “Server System Variables”](#).

## B.3.6 Table Definition-Related Issues

### B.3.6.1 Problems with ALTER TABLE

If you get a duplicate-key error when using `ALTER TABLE` to change the character set or collation of a character column, the cause is either that the new column collation maps two keys to the same value

or that the table is corrupted. In the latter case, you should run `REPAIR TABLE` on the table. `REPAIR TABLE` works for `MyISAM`, `ARCHIVE`, and `CSV` tables.

If `ALTER TABLE` dies with the following error, the problem may be that MySQL crashed during an earlier `ALTER TABLE` operation and there is an old table named `A-xxx` or `B-xxx` lying around:

```
Error on rename of './database/name.frm'
to './database/B-xxx.frm' (Errcode: 17)
```

In this case, go to the MySQL data directory and delete all files that have names starting with `A-` or `B-`. (You may want to move them elsewhere instead of deleting them.)

`ALTER TABLE` works in the following way:

- Create a new table named `A-xxx` with the requested structural changes.
